This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE

MARINE ENGINEER,

A MONTHLY JOURNAL OF

Marine Engineering, Shipbuilding, and Steam Navigation.

EDITED BY WILLIAM GEORGE NEAL.

Vol. III.—From April, 1881, to March, 1882.

LONDON:
OFFICE FOR ADVERTISEMENTS AND PUBLICATION, 3, AMEN CORNER,
PATERNOSTER ROW, E.C.

1882.

INDEX.

EDITORIAL NOTES.

American Accelerating Gun, 260
Allan Line, &c., 2
Amending the Code of Regulations to Engineers in R. N., 148
American Ferry Boat "Solano," 26
American New Fire Boat, 3
Anti-corrosive Paints and Protections, 194
Armour Plated Vessels, 170
Cables Broken at Sea, 194
Cargo carrying, Vessels in Steel and Iron, 122
Chinese Gun Boats, 121
Chinese Steamer "Meifoo's" first arrival, 217
City of Worcester, 259
Clyde Building Trade, 217
Cost of Steel Ships and Iron Ships, 169
Deputation from the Chamber of Shipping, 2
Disaster on the Solway Steamship, 193
Discharge of Rubble or Concrete Blocks, 122
Electric Light, 193
Electric Lighting of the "Inflexible," 74
Engine Room Artificers, 193
Engine Work, its Value, &c., 169
Experimenting with Torpedoes, 74
Explosion at the Launch of the "City of Rome," 73
" of the "Doterel," 145
Fleuss's Diving Dress, &c., 50
Gas Explosions on Coal Laden Ships, 25
Jury Rudder, 217
Launch of a Floating Derrick, 74
"Lighting" Torpedo Boat, 97
"Livadia," Failure of Boiler Steel Plates, 26
Liverpool Docks and London Docks, 240
Management of our Dockyards, 98
Manganese Bronze, 25
Mediterranean Deep Sea Soundings, 51
Mersey Tunnel, 97
Milford Haven New Docks, &c., 240
Navy Estimates, 1
New Docks at Gravesend and Tilbury, 145
New Guns for the Navy, &c., 218
New Life Saving Beacon, 50
Oil as an Aid to Still the Waves, 240
Panama Canal, &c., 239
Polyphemus, 73
Plimsoll Load Mark, 240
Principle of Forced Combustion, &c., 146
Professor Raoul Pictet's Invention, 121
Royal Naval Engineers, 260
Russian Commercial Fleet, 2
Salvage by Raising Sunken Vessels, 74
Sayer's Air Bags for Sides of Ships, 122
Seagoing Engineers Associations, 170
Shah, The, 2
Status of the Engineers R. N., 26
Steering by Electricity, 98
Sir John Hay on the British Navy, 26
Sub-marine Telegraph and their Cables, 218
Sub-marine Torpedo Boat, 50, 98
Tonnage Measurement, &c., 146
Torpedo Boats, 259
Tunnels, Foreign, 259
Trajan Theodoresco Sub-marine Torpedo Boat, 121
Tweddell's Hydraulic Machine Tools, 49
Voyage of the Inflexible, 170
Warrant Officers in H. M. Navy, 51
Wreck of an Italian Barque, 1
"Xerotine Siccative," Explosion of 239

ILLUSTRATED ARTICLES.

"Almirante Brown," Trial Trip of the, 105
An Account of Experiments made by a Board of United States Naval Engineers with screw propellors of different material and dimensions, applied to the United Fish Commissions' steamer, "Look-out," with the hull coppered and not coppered. Pages 100, 101, 126 to 128, 173 to 176, 195, 196, 221
Bourry's Dynamometrical Governor, 180 to 183
" Improvements in Steam Boilers and Steam Joints, 226 to 228
Cook and Mylchreests Split Boss Propeller, 60
Donovan's Boat Lowering Apparatus, 202 to 204
Experimental Researches into the Properties and Motions of Fluids with Theoretical Deductions therefrom, 228, 229
Fresh Distilled Water at Sea, 134
Groom's Illuminating Oil Feeder, 202
Henderson's Patent Firedoor, 247, 248, 249
Hydraulic Machine Tools, Tweddell's System, 152, 153, 154
Hydromotor, 148, 149
Improved Boat Lowering Apparatus, 10, 11
" Fog Horn, 12, 15
" Method of Stowing and Discharging Torpedoes from Torpedo Boats, or other Vessels, 219, 226a
Influence of cut-off and length of Connecting Rod on Working of Steam Engines, 56, 57, 58, 79, 80, 81

Liardet's Patent Propeller, 204, 205
Lightfoots Patent Self contained Dry Air Refrigerator, 150, 151
"Livadia," Peculiarities of Behaviour of Steel Plates supplied for the Boiler of the Imperial Russian Yacht, 30 to 40
Mammoth Fire Boat, 12, 13
Merryweather and Son's Patent Steam Fire Engine, 262 to 267
Merton Hall (New Screw Steamer), 241, 248a
Mild Steel in French Arsenals, 55, 56, 82 to 88, 104, 105, 123, 124
Morris & Bennett's Patent Safety Boat Lowering Apparatus, 60, 61
Norton Power House and Ship Ventilator, 251
On Strength of Crank Shafts, 62 to 66, and 91
On the Progress and Development of the Marine Engine, 128 to 132, 155 to 157, 176 to 180, 196 to 200
Orvis Smoke Consuming and Fuel Saving Apparatus, 110, 111, 112
Patent Lightning Speed Check Governor, 249, 250
Patent Anchor, 89, 90
Polyphemus, 107 to 110
Repairing a Broken Crank with Wire Rope, 58, 59
Simey's New Steam Steering Machine, 88, 89
Steam Quarter Master, 132
Whyte's Removable Boiler Bearers, 42
Youngs Compound Engine, 40 to 42

GENERAL INDEX.

"Admirante Brown," Trial Trip of the, 105
An Account of Experiments made by a Board of United States Naval Engineers with screw propellers of different material and dimensions applied to the United Fish Commission's Steamer "Lookout," with the hull coppered and not coppered, Pages 100, 101, 126 to 128, 173 to 176, 195, 196, 221
Anti-Corrosive and Anti-Fouling Compositions, 134
Anti-Fouling and Anti-Corrosive Compositions, 152
Anti-Fouling Compositions, 201
Asbestos Packing, 123
"Berthon" Collapsible Boat, 184
Boiler Incrustation, 78
Bourry's Dynamometrical Governor, 180 to 183.
  ,, Improvements in Steam Boilers and Steam Joints, 226 to 228
Canada, H.M.S., Launch of, 140
Charge against Chief Engineer of a Wilson Liner, 221
City of Rome, 172
  ,, ,, Launch of, 76
Cook & Mylchreest's Split Boss Screw propeller, 60
"Conqueror," H.M. Ship, 147
Cornish Life Saving Apparatus, 123
Corrosion of Iron and Mild Steel, 17, 18
Docks at Liverpool, 154
Donovan's Boat Lowering Apparatus, 202 to 204
Ead's Ship Railway, 243
Enthracite, Experiments with the Perkin's Machinery of the Steam Yacht, 6, 7, 8, 9, 42, 43, 51, 52, 53.
Ericcsson "Destroyer," 16, 17
Experimental Researches into the Properties and Motions of Fluid with Theoretical Deductions therefrom, 228, 229
Foulger's Antifouling Composition, 182
Fresh Distilled Water at Sea, 134
Groom's Illuminating Oil feeder, 202
Henderson's Patent Firedoor, 247, 248- 249
Hydraulic Machine Tools, Tweddell's System, 152, 153, 154
Hydromoter, 148, 149
Hydraulic Machinery on Board Ship, 214
Improved Boat Lowering Apparatus, 10, 11
  ,, Fog Horn, 12, 15
  ,, Method of Stowing and Discharging Torpedoes from Torpedo Boats or other Vessels, 219 and 226a
Influence of cut off and length of connecting Rod on working of Steam Engines, 56, 57, 58 79, 80, 81
"Inflexible," H.M. Ship,
Institution of Civil Engineers, 54, 243, 244, 245, 246
  ,, Mechanical Engineers, 99
  ,, Naval Architects, 27, 28, 29, 30
Iron and Steel as Constructive Materials, &c. 124, 125
Liardet's Patent Propeller, 204, 205
Lightfoots Patent Self contained Dry Air Refrigerator, 150, 151
Lightfoot's Dry Air Refrigerator, 201
Limitations of the Steam Engine, 3, 4, 5, 6
Lubrication of Refrigerators, 213
Luminous Paint, 112, 113
"Livadia," Peculiarities of Behaviour of Steel Plates supplied for the Boiler of the Imperial Russian Yacht, 30 to 40
Machinery at Birkenhead, 150
Mammoth Fire Boat, 12, 13
Merton Hall (New Screw Steamer), 241, 248a
Masonry Works at Dublin Custom House Docks, 170
Merryweather and Son's Patent Steam Fire Engine, 262 to 267
Mild Steel in French Arsenals, 55, 56, 82 to 88, 104, 105, 123, 124
Morris & Bennett's Patent Safety Boat Lowering Apparatus, 60, 61
Naval and Submarine Exhibition, 147, 257
Navy Estimates, 12, 13, 14, 15, 16
New Dock at Leith, 99
New Marine Monsters, 222
Norton Power House and Ship Ventilator, 251
Notes on Anchors, 88
Notes Relating to the Proper Method of Expansion, &c., 241
Ocean Steamship Machinery, 225, 261, 262
On Strength of Crank Shafts, 62 to 66, and 91
On the Progress and Development of the Marine Engine, 128 to 132, 155 to 157, 176 to 180, 196 to 200
Orvis Smoke Consuming and Fuel Saving Apparatus, 110, 111, 112
Patent Lightning Speed Check Governor, 249, 250
Patent Anchor, 89, 90
Polyphemus, 107 to 110
"Polyphemus," H.M. Ship, 75, 76
"Progreso," Twin-Screw Steamer Dredger, 222
Relative Corrosion of Iron and Steel, 77, 78, 101, 102, 103, 104
Repairing a Broken Crank with Wire Rope, 58, 59
Rocket Life Saving Apparatus, 9
"Rome" and "Clyde" New S.S., 171
Roth Patent Sea Safe, 194
Royal Marine Engineers, &c., 224, 225, 246
Sanitary Point, 113
Sheerness Dockyard, 100
Silicate Cotton or Slag Wool, 148
Simey's New Steam Steering Machine, 88, 89
Steam Quarter Master, 132
Suffield's Patent Freshwater Distilling Apparatus, 112
Torpedo Boat for Danish Government, 215
Towing Hawsers, 213
Van Speybrouck's Anti-Fouling Composition, 184
Whyte's Removable Boiler Bearers, 42
Youngs Compound Marine Engine, 40 to 42

LETTERS TO THE EDITOR.

Anti-Fouling and Anti-Corrosive Composition, 165, 166, 167, 190 212, 236
Carpenters and Shipwrights in H.M. Royal Navy, 256
Collapsing of Marine Boiler Furnaces, 164
Erratum, 211
Formulæ and Results for the H.P. of a Compound Steam Engine, 23
Gordon Castle, 191
Gross Register Tonnage, 22
Improvements in the Navy, 190
Loose Propeller, 71
Loss of Life at Sea, 167, 212
Marine Governors, 237
Perkins's Boiler, 237
Preservation of Food, 237
Saving Life and Property at Sea, 212
Sea-Going Engineers' Association, 190, 212, 256
"Status" of H.M. Naval Engineers, 118
"Status" of Marine Engineers, 140, 211
Steamer being Towed, &c., 257
Steam Yacht Competition, 118
To ascertain the Pitch of a Four-Bladed Screw Propeller, 164, 190
Tonnage of Ships, 71

INDEX.

BOOKS REVIEWED.

British Wild Flowers, 190
How to Manage a Steam Engine, 23
Iron Founding, 190
Lectures on Naval Architecture and Marine Engineering, 235
Naval Hygiene, 235
Practical Guide to the use of Marine Steam Machinery, 23, 211
Stock Requisition and Private Log Book, 211
Transactions of the Institution of Naval Architects of 1881, 235
Wood-wooking Machinery, 23

PATENTS.

Recent Applications for Patents connected with Marine Engineering Ship Construction, and Mechanical Appliances for uses in Ships, 22, 48, 71, 95, 120, 143, 168, 191, 216, 238, 258, 274
Board of Trade Examinations, Return of Engineers reported to have passed Examinations under the provisions of the Merchant Shipping Act of 1854, 22, 48, 72, 96, 120, 144, 168, 192, 216, 238, 258, 274

PARAGRAPHS and NOTES AND NOVELTIES.

The Marine Engineer,

LONDON, APRIL 1, 1881.

EDITORIAL NOTES.

MR. TREVELYAN has just laid before the country his Navy estimates for the new year, and there is much matter therein for congratulation to the country at large. Before detailing these points of advantage we would note that the Engineers as a body are somewhat passed over, leaving many matters of grievance still untouched and unredressed. That the engineers deserve the greatest possible consideration at the hands of the Admiralty may be fully realized; that engineers, stokers, and artificers considerably exceed the whole number of seamen in the Navy. We hope still by the energetic representation of their needs and grievances to aid in pressing these matters upon the attention of the Government. In ships we are promised a rapid completion of those now on the stocks, including the new steel cigar ironclad, the *Polyphemus*. The practical results from this vessel are watched with much interest as it may be the precursor of a revolution in marine construction. Pending, however, the deductions that may arise from the *Polyphemus*, we are promised next year two sea-going cruisers which shall combine the speed of the *Leander* to run 16 knots, and with guns of greater power than the *Thunderer* or the *Devastation* to pierce 16 in. plates. This is a marked advance in the fighting ship of the future, as a point much to be regretted in our present most powerful ironclads, is their great unwieldiness and want of sea-going and roomy qualities. In guns, too, the Admiralty has at last recognized the fact that Woolwich is not infallible, and that an independent committee of scientific naval and engineering experts are most likely to be able to give good and unbiassed reports upon any new systems of guns submitted to their opinion. At any rate the system of breech loading is fully adopted, and we are promised in a year or two a very large number of the largest size of breech loading cannon, constructed with improved explosive chambers and to the latest designs for improved penetration. On the whole the Navy and Admiralty seem full of life and energetic improvement, and are thus a credit and an ornament to the country.

We cannot compliment the Italians as a nation on their sailor-like qualities. There are few men less reliable in a storm or ship-wreck than the excitable natives of Southern Europe. A fearful story of undisciplined terror has reached us as occurring during the wreck of an Italian barque off Cooney Island, when bound for an American Port. The tale is told by the only survivor, that when the vessel struck the captain offered brandy to the crew that they might die drunk. The sea seems to have reminded them of higher duties by washing the brandy out of their reach. Their next appeal was to an image of the Madonna, before whom they knelt shrieking and imploring the Madonna to rescue them. When the waves washed the Madonna away also, they seem to have given themselves up to demoniacal despair, the steward pulling out his knife and cutting his throat. Two or three others seem to have followed his example, and in the midst of this horrible scene the vessel broke to pieces, and the crew of fourteen dead and living were precipitated into the sea. That one sailor by clinging to wreckage reached the shore and lives to tell the tale, forcibly points the moral that all or many might have been saved by well directed and energetic preparations for safety.

Russia is by no means so insignificantly represented amongst the commercial navies of the world as she may be considered by some. The Russian finance minister has just concluded an inquiry through the Department of Manufacture or Commerce into the state of the Russian Commercial Fleet. The Ports of the White Sea have 11 steamers and 575 sailing vessels; Baltic Ports, 63 steamers and 578 sailing vessels; the Black Sea and Sea of Azoff, 171 steamers and 1,964 sailing vessels; the Caspian, 36 steamers and 1,004 sailing vessels; and the Pacific Ocean, 15 steamers. In all, they amount to 296 steamers and 4,121 sailing vessels, of which 1,196 are employed in deep sea navigation, and 3,221 in the coasting trade. A great number of these are also Russian built, viz., 3,695 out of the total, leaving only 722 as having been procured abroad. There is no doubt an immense future before Russia as a commercial and naval country when she is blessed with a more enlightened Government, and her many riches are more fully developed.

The firm of Messrs. Allan Brothers, & Co., are an instance of the great development that has attended the energy and skill of many of our large shipping lines. The Allan Line has only been established some sixty years, and only sailing ships of comparatively small burthen were employed during the first thirty-two. The first steamer of 1,500 tons was built only some twenty-eight years ago, and when we now state that the firm owns twenty-four splendid steamers and a total of 100,000 tons, a remarkable proof is afforded of the energy and skill which must have been needed to create and foster a business of such magnitude. The latest addition to the fleet is the *Parisian* steel built by Messrs. R. Napier & Sons, of Glasgow, which has had a most satisfactory trial on the Clyde, and is now about to take her place in the service from the Mersey. The *Parisian* is one of the most perfect of a splendid line.

An important deputation from the Chamber of Shipping waited upon Mr. Chamberlain to demur against further restrictive legislation upon grain cargoes, pointing out that they believed the present Act, if fully carried into effect, gave ample power to the President of the Board of Trade to put a stop to dangerous loading. Colonel Hill gave an example trom Messrs. Turnbull's returns that their ships had made 271 voyages safely from the Black Sea and Sea of Azoff with grain in bulk. Mr. Glover drew attention to the fact that ship-owners who had gone to considerable expense to comply with the requirements of the present Act would be denied the benefit of the exemptions offered on those conditions. Other members stated that to require "feeders" in single decked ships would, in all probability, create a new source of danger to life and property, by increasing the number of openings by which the sea might get into the hold. Mr. Chamberlain was, however, not disposed to admit that there was not still great need for further precautionary measures against loading in bulk as the last three months have shown 25 grain and 77 coal vessels have been lost out of 197. We, however, have much satisfaction in drawing our readers' attention to the fact that Mr. Chamberlain stated the Board were quite prepared to pass vessels constructed on a safe plan for the grain trade, such as he was aware were now built. We cannot do better than refer our readers to several satisfactory plans for grain loading, such as we have illustrated in past issues. We are glad to note also that Mr. Chamberlain proposes to bring a Bill in soon for the formation of a Shipping Commission to be elected by ship-owners, and to act as arbitrators in disputes between ship-owners and the Board of Trade. Many of our readers must have felt the want of such a tribunal, and it is to be hoped that many vexed questions of load line will be satisfactorily settled by it.

The *Shah* is to be fitted with an entirely new and more powerful armament, advantage being taken of her refit to effect this. It is not before it was wanted, as it must be fresh in the memory of all how she and the *Amethyst* allowed the Peruvian ship, *Huascar*, to slip through their fingers. She was then armed with eight comparatively useless 64-pounders, and with only a couple of 12-ton nine inch revolving chase guns, and sixteen six-and-a-half ton 7-inch broadside guns. In her new armament she is to be furnished with two 8-inch and twenty-four 6-inch long breech-loading rifled weapons with great penetrative power, the 64-pounders being wholly dispensed with. In addition to the above she will be provided with two Gatling guns, and six Nordenfelt guns, which are excellent weapons at close quarters or against torpedo craft. he will also be fitted with twelve 14-inch Whitehead torpedoes. The *Shah* will thus, as far as her armaments go, be one of the most powerful cruisers afloat, and from her ample interior accommodation certainly one of the pleasantest ships afloat.

THE Americans are proposing to construct a new fire boat on a large scale, for the extinction of the numerous fires which occur in New York and Brooklyn on the river front. The hull is of iron, 250 ft. long and 40 ft. beam. She has two distinct engines driving the paddle wheels, so that one may go forward whilst the other goes back so as to enable her to turn on a centre in almost any direction. The boilers are 3,000 horse-power, and are so constructed that their full power may be used either on the paddles or on the pumping engines. The discharge pipes are two in number, fitted to a vertical stand pipe like a mast in the fore part of the vessel. This stand pipe is supplied by water from the forcing pumps. The upper discharge pipe is moveable on trunnions anywhere round the vertical pipe, and has a variable discharge orifice of from 6 to 10 in. diameter. The lower discharge pipe, also moveable on trunnions, has a nozzle of 20 in. diameter. These nozzles are enormous, the largest being at least 400 times the volume of an ordinary 1 in. fire nozzle. The boat is also fitted with a gun to fire wooden projectiles to break down any opposing wall or confined space, to which no other access can be obtained. This is altogether a startling innovation in fire engines and promises to immediately flood any fire within reach.

ORDER FOR ANOTHER LARGE STEAMER.—Messrs. James and George Thomson, the builders of the *Servia*, have just closed a contract with the Hamburg American Steamship Company, to build for them a very large steamer for the Hamburg and New York passenger and mail service. She will be a vessel of 5,500 tons, of somewhat similar proportions to those of the Allan liner *Parisian*, and will be the largest steamship in the German mercantile marine.

THE following vessels are now on the ways, being constructed on the Tyne. At Messrs. C. Mitchell & Co.'s yard the four gunboats for China are nearly completed; the same firm have seven steamers on the ways. Messrs. Wigham, Richardson & Co. have five large new steamers on the stocks. Messrs. Leslie & Co., at Hebburn, have eight new steamers in hand, besides a large new steamer in the graving dock, fitting out for Liverpool owners. Messrs. J. Schlensiger & Co., have three new steamers in hand. Messrs. Swan & Hunter have three on hand. At the Wallsend Shipway the Antwerp mail steamer *Helvetia* will shortly be completed, after which she will proceed to Antwerp to resume her station, from thence to New York. Messrs. Clelland & Co. have three steamers on the ways repairing. The Tyne Iron Shipbuilding Co. have four boats on the stocks. Messrs. Palmer & Co. have four new steamers on hand at Willington Quay, and several in course of construction at Jarrow. Messrs. J. T. Eltringham & Co. are building three or four tugs at South Shields. Messrs. Thomas and William Smith have three new coasting steamers on hand. From the foregoing it will be seen what magnitude shipbuilding is now assuming in the Tyne, giving employment to several thousands of men, who are enjoying excellent wages.

THE LIMITATIONS OF THE STEAM ENGINE.

From the Journal of the Franklin Institute.

By WILLIAM DENNIS MARKS, Ph.B., C.E.,
Whitney Professor of Dynamical Engineering, University of Pennsylvania.

PERHAPS there is no more unsafe proceeding in science than to attempt to predict the limitation of the development of any of its results. Yet the theory of the steam engine has so far been developed as to seem to permit us to mark out the boundaries of its progress with tolerable accuracy.

At least, we trust that a full criticism of its present deficiencies, and a deduction of its limitations from known laws, will interest such of our readers as are engaged in the improvement of this machine, to which our civilization is more indebted for its advancement than to any other one thing.

In this article we will consider the steam engine alone, as it is in no wise responsible for the economy of the boiler which supplies the steam, or for the losses incurred in conveying the steam from the boiler to the engine.

The boiler should be considered apart from the engine, and it is well to incidentally remark here that the performances of the best types of boiler leave but little room for improvement so far as evaporation is concerned.

It is rather in the utilization of the steam after it reaches the engine that we must look for progress, and in this point, we take it, lies the value of a thorough investigation of the machine itself.

The well-known formula for the horse-power of a steam engine* contains three factors, which can be varied at will: the mean effective pressure, the volume of the cylinder, and the number of strokes per minute.

Concentration of power in a small space is the greatest attribute of the steam engine; it is its power to concentrate the strength of thousands of horses in the space of an ordinary room that renders the steam engine so useful and indispensable to us.

For this reason we cannot go on increasing the volume of the steam cylinder indefinitely without a proportionate increase in power, and it is only necessary to remark to mathematicians, with regard to the proportions of the cylinder, that that cylinder whose stroke equals its diameter contains the maximum of volume with the minimum of condensation surface.

The importance of reducing condensation surface is becoming more and more appreciated among engineers, and shortening the stroke will prove less of a bugbear when the laws of inertia, as applied to the reciprocating parts of a steam engine, are better understood.

Shortening the stroke has the further advantages of shortening the space passed over by the piston head during a given number of strokes, and consequently of reducing the wear on the piston head as well as of rendering the engine more compact for a given power.

The following formula gives for any assumed horse-power, mean effective pressure, and number of strokes per minute, the required common diameter and stroke of cylinder, *in inches*:

$$d = 79{\cdot}59\sqrt[3]{\frac{(HP)}{NP}}\ \dagger$$

Concentration being attained, the next important consideration that arises is *economy of steam*, and this is the battle ground upon which the struggle for supremacy among our engine builders is to-day being practically fought out, while the physicists are quite as hotly engaged in a dispute as to the relative theoretical merits of steam, hot air, and electric engines, into which we will not enter.

Practically, we think that, as far as the steam engine is concerned the impossibility of supplying to the steam in the cylinder any appreciable amount of heat by means of steam or hot air jackets is acknowledged by all, and the jacket is only expected to keep the cylinder warm, and prevent it from abstracting heat from the steam inside the cylinder.

---

* $\frac{PLAN}{33000} = (HP)$. In which P = mean effective pressure per square inch, L = length of stroke in feet, A = area of piston in square inches N = number of strokes per minute, (HP) = indicated horse-powers, $\frac{AL}{144} = V$ = volume of cylinder.

† *The Relative Proportions of the Steam Engine*, p. 26. Marks.

The jacket proving imperfect, we must find other means for preventing condensation by cooling, and they are these: Diminution of condensation surface, as already stated above, and shortening of the duration of the time for condensation, which means an increase in the number of strokes of the piston. The effect upon the structure of the engine of increased rotative speed is not injurious to the engine, as so positively stated by many engineers; but, if attempted, rapid speed requires a far greater knowledge of the dynamics of the steam engine than has as yet been applied to it by many constructors, and will almost inevitably shake to pieces a faultily designed structure.

The length of the crank pin and shaft bearings must also increase directly with the number of revolutions made, while their diameter, within ordinary limits as to pressure and speed, has no appreciable effect upon the heating at the bearing; but when we consider the practical fact, that the eccentrics, possibly because of greater speed of rubbing surfaces, are always sources of large frictional losses, it would seem best to make the diameters of all bearing journals just as small as the pressures allowable upon the surfaces of contact will permit. Much yet remains to be determined with regard to the laws controlling bearings. A very interesting work has been published on *Friction and Lubrication*, by Professor Thurston, but it is to be regretted that he has formulated the results of his experiments with so much positiveness, as other and careful experimenters have found it difficult to obtain results which clearly verify each other.

He has shown conclusively that the coefficient of friction is much affected and reduced by the state of the rubbing surfaces, by the method of lubrication, and by the quality of the lubricant.

Perfect, almost mirror-like, surfaces reduce the coefficient of friction far below the 3 to 5 per cent. formerly stated by Morin as a minimum, provided a continuous lubricating apparatus is used with good sperm oil, and it will be found that a costly lubricant such as sperm oil is cheapest where care is exercised not to waste in its application.*

The important influence of the number of turns upon the length of bearings has not been clearly enough understood to prevent accidents from heating of the crank pins and bearings, which is one of the most annoying mishaps which can befall an engine, and at times requires the utmost vigilance of the engineer for its prevention.

The great difficulty attendant upon making bearing and shaft press uniformly throughout the length of the journal has almost forced the use of Babbitt or soft metal for high speed engines, and where proper care is taken in proportioning the results have justified its use.

Crank pins shrunk in by heating the crank, are apt to be out of truth, no matter how carefully the work has been done, as heat is apt to warp the crank.

Pins should be forced in cold, or the crank and pin be forged in one piece as in the case of most small double cranks.

High rotative speed, while increasing the power of the steam engine, also renders it more compact and diminishes the weight of the fly-wheel necessary to obtain regularity of speed.

Rotative speed has, however, its limitations, independently of the trouble sometimes caused by the heating of bearings.

For instance, it can be shown that if the safe stress in tension upon cast iron equals 1800 pounds per square inch, that a cast iron ring can be revolved safely at a maximum lineal speed of 8,000 feet per minute, or thereabouts, which at once places a limitation upon the rotative speed of the fly-wheel, and demands reduction of its diameter as the rotative speed is increased.

Let N = the number of revolutions per minute.
,, D = the diameter of cast iron ring, in feet.

We have

$$\pi D N = 8000$$

or

$$D N = 2546.$$

This formula would limit the diameter of the fly-wheel of a pair of engines, to make 600 revolutions per minute, lately proposed by the distinguished engineer, Mr. Chas. T. Porter, to about 4 feet.

Of course, as the tensile strength of the material of which the fly-wheel is made is increased, the lineal speed at which it can be driven is increased.

If we take 5000 pounds per square inch as the safe tensile strength of the steel tire of a locomotive, we find its lineal speed to be limited to about 2½ miles per minute, or 150 miles per hour, and it only remains for our engineers to provide boiler capacity and road bed adapted to such speeds, in order that they may be realized by a properly constructed locomotive.

This speed would shorten the time between New York and Philadelphia to 36 minutes.

High rotative speed necessitates special precautions as to the weight of the reciprocating parts.

If we impose the condition that the initial and final stresses upon the crank pin be equal, we must make the centrifugal force of the reciprocating parts (piston, piston rod, cross head and connecting rod), supposed to be concentrated at the crank pin, equal to half the difference of the initial and final steam pressures upon the whole piston head.

High rotative speed has also demanded a change in the form of the connecting rod, which was formerly largest at its mid-length, but has of late years been made largest at the crank pin end; a consideration of the stress upon it, due to its own inertia, would place the point of greatest stress at 0·578 of its length from the cross head end, but the stresses due to the twisting of the crank pin in its boxes recommends as a measure of safety that the rod be made largest at the crank pin neck, and tapered down from that to the cross head.

In a properly proportioned engine, of any assumed horse-power, the *only* method of reducing the weight of the moving parts is to increase the rotative velocity; lengthening the stroke will not do it.

The points of interest with regard to the volume of the steam cylinder and the rotative speed of the engine having been touched upon, there remains to be considered the mean effective pressure of the steam.

In the "MARINE ENGINEER" for February, 1881, the writer has shown, under the assumption that the steam expansion curve is an equilateral hyperbola, that the most economical point of cut-off for steam engines is determined by dividing the absolute back pressure by the absolute inital pressure of the steam.

Indicators do not give such curves, even if in perfect order, unless the steam is a little wet; but the approximation is sufficiently close for all practical purposes.

A more accurate way would be to say that the most economical point of cut-off is attained when the final steam pressure equals the back pressu e; but our first statement is more convenient in form and will serve our purpose, with all the practical accuracy necessary,

Let P = the mean effective pressure of steam in pounds per square inch.

Let P_b = the initial absolute pressure of steam in pounds per square inch.

Let B = the back absolute pressure on piston in pounds per square inch.

Let e = the fractional part of the stroke at which the steam is cut off.

Let V = the volume of the steam cylinder in cubic feet.

Then we have

$$P = e P_b \left[1 + \text{nat. log.} \frac{1}{e} \right] - B$$

Let (HP) = the indicated horse-power.
,, S = the specific volume of the steam for pressure, P_b.
,, W = the weight of water used per horse-power.

We have

$$(HP) = \frac{P L A N}{33000}$$

in which L = the length of stroke in feet.
N = the number of strokes per minute.
A = the area of the piston head in square inches.

Therefore.

$$(HP) = \frac{\left\{ e P_b \left[1 + \text{nat. log.} \frac{1}{e} \right] - B \right\} V N}{33000} \times 144$$

since $144\, V = L\, A$.

The quantity of water used during one minute is

$$62\tfrac{1}{2} \frac{e V N}{S}$$

62½ pounds being taken as the weight of one cubic foot of water.

---

* Let l = the length of the crank pin, in inches.
,, L = ,, stroke in feet.
,, (HP) = the indicated horse-power.

Then, for marine propeller engines, a practical formula, giving safe lengths, would be

$$l = 0{\cdot}622 \frac{(HP)}{L}$$

One-fourth of this length will serve safely for side-wheel or stationary engines.

For locomotive engines practice seems to prove that $l = \cdot013\, d2$ is a safe value, in which d = diameter of the steam cylinder, in inches.

For crank shaft bearings, letting R = the whole maximum weight on bearings, and N = the number of strokes per minute, we have $l = \cdot000005\, R\, N$.

Therefore, the weight of water used per horse-power is

$$W = \frac{62\frac{1}{2}\,\frac{e\,V\,N}{S}}{\frac{144}{33000}\left\{e\,P_b\left[1 + \text{nat. log. }\frac{1}{e}\right] - B\right\}V\,N} = \frac{14323\,e}{S\left\{e\,P_b\left[1 + \text{nat. log. }\frac{1}{e}\right] - B\right\}}$$

If in this last formula we substitute $\frac{B}{P_b}$ for e, we obtain the theoretical minimum quantity of water to be evaporated per horse-power, and

$$W = \frac{14323}{P_b\,S.\ \text{nat. log. }\frac{P_b}{B}} = \frac{6220\,3}{P_b\,S\ \text{log. }\frac{P_b}{B}}$$

For one horse-power per hour we would have, multiplying by 60,

$$60\ W = \frac{373218}{P_b\,S\ \text{log. }\frac{P_b}{B}}$$

As, for instance, for a non-condensing engine having a gauge pressure of 45 pounds, and cutting off at ¼ the stroke, we find the minimum limit of evaporation of water required to be about 24 pounds of water per horse-power per hour.

Mr. Charles E. Emery has experimentally realized as low as 39 pounds of water per horse-power per hour with the given pressure, in small non-condensing engines.

If, in the last formula, we regard the product of the pressure, and the specific volume, $P_b\ S$, as constant, which it is with a considerable degree of approximation, we observe that the economy varies directly as the log. $\frac{P_b}{B}$, showing that both Watt and Oliver Evans were partially right in their attempts to increase the economy of the steam engine. Watt was right in perfecting more and more the vacuum obtained, and Evans in increasing the steam pressure at the boiler. Neither of them were wholly astray, but were soon met, and their progress stopped by the slow increase of the economy beyond certain limits, and by the practical difficulties arising in the pursuit of a partially apprehended law.

It is evident that we are limited as to the steam pressure, and that a great increase of that, or a great decrease of back pressure, by reason of more perfect vacuums, will render the point of cut-off so early, and the mean effective pressure so low, that the necessary increase of volume in the steam cylinder will prevent that compactness and concentration of power so desirable in the steam engine; and, although it has already been shown that high rotative speed aids in rendering the engine compact, we are also limited in that direction.

Regularity of speed is an imperative condition in all engines used to drive high-speeded machinery; under such circumstances, regularity becomes the first requisite, and to it all other considerations must be subordinated.

Mr. G. H. Corliss, with his automatic cut-off engine, was the first to satisfactorily solve this problem.

With a constant steam pressure and a constant load, an engine will run, under the control of a throttling governor, with an approximation to regularity determined by the sensitiveness of the governor. With a throttling governor every change of the steam pressure, every change in the load causes a change in the speed of the engine, no matter how well proportioned it may be.

The laws regulating the centrifugal governor are such as to prevent it from ever becoming a very perfect mechanism, for the engine *and governor* must go fast in order to go slow, and *vice versa*. With an automatic cut-off governor, the speed will be held with regularity under all steam pressures and loads within its capacity, the approximation to perfection attained being determined by the proportions of the fly-wheel and the sensitiveness of the governor.

Governors in which the inertia of the balls is utilized to check any attempted change of speed, without an appreciable change of speed in the governor itself, will ultimately supersede the centrifugal governor, which is full of radical defects.

Valve motions, actuated by a weight or spring released automatically by the governor, are comparatively so slow in their motions as to prevent high rotative speeds and short strokes. This form of valve motion has been elaborated with great skill and ingenuity on such engines as the Corliss, Harris-Corliss, Reynolds-Corliss, Wheelock's and Brown, which, so long as long stroke and slow rotation is adhered to, leave but little to be desired on the score of regularity of motion or perfection of workmanship.

To a different class belong the Porter-Allen and the Buckeye engines; in these engines, which are the exponents of high rotative speeds and short strokes, the cut-off of the engine is actuated by means of a link or an eccentric, whose position is regulated by means of a centrifugal governor, and, whatever the speed, the valves must keep pace with the engine in its motions.

A large number of valve motions are in use on the various forms of locomotive, marine and stationary engines, throughout the civilized world, and it is perhaps worth our while to practically note the important points of some of the older forms.

The plain hollowed slide valve is the most commonly used on the rougher forms of engines, because of its simplicity; as, however, the earliest point at which it can cut off steam without choking the exhaust is about ⅝ of the stroke, it is not economical with the high pressures of the present day or with the vacuums ordinarily attained in condensing engines.

When a reversing gear is used, the Stephenson link motion is commonly used, where simplicity of mechanism rather than economy of steam is a point to be gained.

With open rods it has a variable lead, decreasing from the dead point; with crossed rods it has a variable lead, increasing from the dead point.

For crossed rods, the position of the piston is nearly constant at the opening of the steam ports; this is a decided advantage. Crossed rods permit a slightly greater length of eccentric rods.

Fastening the link to the ends of the eccentric rods, at a point behind the centre line of the link, as is usually done in American practice, introduces irregularities into the point of cut-off, but does not affect the lead.

When the ends of the eccentric rods are fastened to the link, at points on the centre line of the link, this error does not occur, but larger eccentrics are required, which are sometimes inconvenient.

The mode of suspension of the link is far more important than is usually supposed, as imperfect suspension not only introduces serious errors in the valve motion, but also affects the durability of the construction, by producing excessive slip in the block.

Where a constant lead is desired, using different angles of advance for the two eccentrics will produce a constant lead in one direction of motion, but ruins the action of the valve motion in the opposite direction.

The Gooch link motion is difficult to fit into an engine, because of the distance required between the centre of the crank shaft and the end of the radius rod; it is very easy to handle, and should therefore be used where frequent reversing is necessary, as in the cases of yard locomotives and hoisting engines, even though requiring considerable trouble to fit in.

If a constant lead be a great advantage, this link motion has this advantage. The suspension link for the link proper should be made as long as possible, and the suspension link for the radius rod should be attached as closely as possible to the link block. The tumbling shaft should be placed on the opposite side of the link from the crank shaft.

Allan's link motion, having a straight link, can be more easily fitted up than motions having a curved link; it has all the disadvantages of the Gooch link motion, but, unlike it, has not a constant lead, and has a greater number of parts. Particular attention must be paid to the relative lengths of the tumbling shaft arms for simultaneously raising and lowering the link and radius rod. The Allan link motion does not handle as easily as the Gooch.

Heusinger von Waldegg's link motion is the easiest of all to handle; it can be so arranged as to have very little slip in the block, but cannot be easily attached to all forms of crosshead. It is the simplest reversing gear yet mentioned, and has a constant lead.

Pius Fink's link motion is the simplest reversing gear in existence which at the same time can be adjusted as a cut-off; it has a constant lead, but a limited range of action, and in this point is inferior to all the others, as well as being irregular in its variation from its calculated positions.

However, if carefully designed it will do good work, and is very easy to handle and very durable.

The fact that it is impossible to avoid choking the exhaust, and the consequent compression of the steam, thereby reducing the power of the steam engine whenever the attempt is made to cut off early in the stroke with a single valve has led engineers to devise double valve motions which will effect an early cut off of the steam, independently of the motion of the hollow of the slide valve relatively to the exhaust.

To this type belong the valve motions of the Porter-Allen and

Buckeye engines, both of which show a wide range of action for motion in one direction, and great simplicity of structure.

The Gonzenbach link motion, with its double steam chest, and excessively complicated outside gear, is now almost obsolete; it will not cut off sharply and well, except for very early points, and that, too, only for motion in one direction, and when properly arranged for motion in one direction gives a double admission of steam for motion in the opposite direction; it is difficult to handle, and its complication renders it very liable to break down.

The Polonceau link motion, while it has not the double steam chest or as much complication in its outside valve gear, cannot cut off steam later than $\frac{1}{3}$ of the stroke, and is therefore not very well adapted to general locomotive use where economy is sacrificed to concentration of power.

It is not very difficult to handle, but, like the Gooch, presents some difficulty in adapting to the narrow limits offered by a locomotive.

Meyer's link motion seems to have met with the greatest favour from builders of marine and stationary engines, as it presents a wide range for motion in one direction, and a greater range when used as a reversing motion than any of the others.

The screws which move the expansion blocks are liable to rust or wear, and cause trouble; the expansion valve should have separate eccentrics to work best; it is intricate in its construction, and liable to break down.

It is also difficult to handle, and absorbs much power unless the distribution valve is balanced.

An ingenious modification of the Meyer valve motion is the Ryder cut-off, in which a cylindrical expansion valve, whose edges approach each other after the manner of an isosceles triangle wrapped around a cylinder, is moved around its axis by means of the governor, so as to have the same effect as that of increasing or decreasing the distance between the expansion blocks of the Meyer cut-off.

In order that we may make ourselves clearly understood, we recapitulate.

A really good steam engine should possess the following qualities: Concentration of power, economy of steam, regularity of speed, simplicity of design and durability of construction.

We have endeavoured to mark the limitations of the first three attributes of a good engine; the last two must be worked out in the shop.

We are perhaps, too bold in our prediction, but it seems to us that the engine of the future will have a cylinder whose stroke is equal to its diameter, its speed will be limited by the tensile strength of its revolving parts, its bearings will be of great length, its cut off will be determined, approximately at least, by the ratio of the back pressure to the initial pressure, its valve motion will be rigidly in connection with the crank shaft, its reciprocating parts will be so proportioned as to put a nearly constant pressure on the crank pin, its fly-wheel, if it has one, will be proportioned so as not to admit of more than a predetermined variation of speed during one stroke, its governor will no longer be centrifugal, but a revolving pendulum, almost isochronous, and holding the engine, with all necessary approximation, within fixed limitations, to a constant speed.

ADVANTAGE will be taken of the refit of the *Shah*, which will be commenced on the 1st of April at Portsmouth, to provide her with an entirely new and much more powerful armament, but without increasing the number of her chase and broadside guns. The memorable engagement during which the *Shah* and the *Amethyst* permitted the Peruvian turret ship *Huascar* to slip through their fingers, as it were, has not apparently been forgotton at the Admiralty, and in her next commission the *Shah*, though the largest unarmoured frigate in the service, will be able to give a good account of herself in action against an ironclad. She has hitherto carried a couple of revolving 12-ton nine-inch chase guns, 16 six and-a-half-ton seven-inch broadside guns, and eight comparatively useless 64-pounders. In the new armament with which she is to be furnished, her heavy muzzle-loaders will be superseded by the new, long, and narrow B.L.R. weapons, of which she will carry two eight-inch and 24 six-inch guns; the 64-pounders being wholly dispensed with. For boat and saluting purposes she will be fitted with three M.L.R. nine-pound guns of 8 cwt. each, and one seven-pounder; and in addition to the above the *Shah* will be supplied with a couple of Gatling 45 machine guns' six Nordenfelt one-inch guns, and 12 14-inch Whitehead torpedoes. In the number and power of her armament the *Shah* will be one of the most formidable cruisers afloat.

ON THE EXPERIMENTS WITH THE PERKINS MACHINERY OF THE STEAM YACHT "ANTHRACITE."

From the Journal of the Franklin Institute.

By Chief-Engineer ISHERWOOD, United States Navy.

(*Continued from page* 280.)

IN calculating the weight of steam accounted for by the indicator at the point of cutting off the steam in the small cylinder nothing is to be added for condensation in the cylinder due to transmutation of heat into the total power developed up to that point, the heat for that purpose having been expended in the boiler during the generation of the steam. After the closing of the cut-off valve in the small cylinder all the steam thenceforth used to the end of the stroke of the piston of the large cylinder is expanded steam.

In calculating the weight of steam accounted for by the indicator at any point, from the steam pressure there present, allowance must be made for the weight of steam already in the clearance and steam passage of the cylinder when the boiler steam enters, as only the excess over this weight has been drawn from the boiler. The weight of steam in the clearance and steam passage present when the boiler steam enters is calculated from the back pressure against the piston at the commencement of its stroke, and not from the mean back pressure during its stroke. This is why the back pressure at the commencement of the stroke of the pistons is given separately in the table.

The economic results are given for the cost of the indicated, net and total horse-power in pounds of coal, in pounds of the combustible portion of the coal, in pounds of feed water, and in Fahrenheit units of heat consumed per hour. Of these, the latter alone is exact for comparison with the performances of other engines. The cost in pounds of feed water does not include the difference in the total heats of steam of different pressures, and in the total heats of feed water of different temperatures, which the cost in units of heat does. The cost in fuel is variable with the quality of the fuel, with the rate of its combustion, with the kind and proportions of boiler in which it is consumed, and with the skill of the fireman; the fuel measure is therefore not a proper one for the economic efficiency of the engine, *per se*, as compared with that of other engines, for which purpose it furnishes but a rough approximation. The true engineering comparison is for the cost of the *total* horse-power in units of heat consumed per hour. For commercial purposes the comparison should be for the cost of the *net* horse-power in units of heat consumed per hour. The total horse-power representing the entire work done by the steam, both usefully and in overcoming prejudicial resistances within the machine itself, while the net horse-power represents only the work done at the crank pin, which is the useful work available for purposes exterior to the machine itself. The number of Fahrenheit units of heat expended per hour per indicated net and total horse-power developed by the engine, is the product of the multiplication respectively of the pounds of feed water consumed per hour per each of the said horse-powers by the number of units of heat put into that water, namely, the difference between the total heat of the boiler steam and the total heat of the feed water.

If the object be to compare the economic efficiency of two systems of machinery, as a whole, including engine, boiler, method of using the steam, &c., then the cost of the *net* horse-power developed in pounds of fuel consumed per hour is the proper measure, taking care that the fuel used is the same in both cases.

In the various calculations of the quantities in the following table allowance has been made for the different specific heats of water at different temperatures and under different pressures. Also for the different total and latent heats of steam of different pressures. All the steam in the cylinders was in the saturated state, as appears from the difference in the weight of steam accounted for at any point by the indicator and the weight drawn from the boiler.

All the various quantities observed during the experiment were carefully noted personally by experienced assistant engineers of the Navy under the supervision of the Chief Engineers composing the Board. The indicator diagrams were taken by these assistants with every precaution, the indicators having been previously tested, as were also the scales used for weighing the coal and its refuse. Every attention was given to have the results minutely accurate. The cylinders, on trial, showed no leakage, and it is believed the entire machinery was in excellent condition.

Table containing the Data and Results of the Experiment made at the New York Navy Yard on the Machinery of the Steam Yacht "Anthracite" by a Board of United States Naval Engineers.

	Date of experiment (vessel secured stationary to wharf)	August 13, & 14, 1880.
	Number of sets of indicator diagrams, taken half-hourly	48·
Total Quantities.	Duration of the experiment in hours and minutes, consecutively	23.58
	Total number of pounds consumed of Cumberland semi-bituminous coal	4400·
	Total number of pounds of refuse in ash, clinker, &c., from the coal	776·
	Total number of pounds of combustible (gasifiable portion of the coal), consumed	3624·
	Per centum of the coal in refuse of ash, clinker, &c.	17·6363
	Total number of pounds of feed water pumped into the boiler	35114·
	Total number of double strokes made by the pistons of the engine	148154·
Engine.	Steam pressure in the boiler, in pounds per square inch above the atmosphere	316·50
	Steam pressure in the receiver, in pounds per square inch above the atmosphere	10·54
	Position of the throttle valve	Wide open.
	Fraction completed of the stroke of the piston of the 1st cylinder when the steam was cut off	0·5206
	Fraction completed of the stroke of the piston of the 3rd cylinder when the steam was cut off	0·2835
	Number of times the steam was expanded	25.7098
	In none of the cylinders was the steam cushioned, nor was there either steam or exhaust lead	
	Vacuum in the condenser, in inches of mercury	26·75
	Height of the barometer, in inches of mercury	30·023
	Back pressure in the condenser, in pounds per inch above zero	1·6066
	Number of double strokes made per minute by the steam pistons	103·02782
Temperatures.	Temperature, in degrees Fahrenheit, of the external atmosphere	77·5
	Temperature, in degrees Fahrenheit, of the engine-room	98·5
	Temperature, in degrees Fahrenheit, of the injection, or sea water	76·0
	Temperature, in degrees Fahrenheit, of the discharge water	95·0
	Temperature, in degrees Fahrenheit, of the hot well	122·0
	Temperature, in degrees Fahrenheit, of the feed water in the tanks	120·5
	Temperature, in degrees Fahrenheit, of the steam in the boiler, considered as saturated	420·0
	Temperature, in degrees Fahrenheit, of the steam in the 1st cylinder at the commencement of the stroke of the piston, considered as saturated	385·0
Rate of Combustion.	Pounds of coal consumed per hour	183·5883
	Pounds of combustible consumed per hour	151·2101
	Pounds of coal consumed per hour per square foot of grate	11·9869
	Pounds of combustible consumed per hour per square foot of grate	9·8728
	Pounds of coal consumed per hour per square foot of outer heating surface	0·6115
	Pounds of coal consumed per hour per square foot of inner heating surface	0·8142
	Pounds of combustible consumed per hour per square foot of outer heating surface	0·5036
	Pounds of combustible consumed per hour per square foot of inner heating surface	0·6706
Steam Pressures in 1st Cylinder per Indicator.	Pressure on piston of 1st cylinder at commencement of its stroke, in pounds per square inch above zero	201·64
	Pressure on piston of 1st cylinder at the point of cutting off the steam, in pounds per square inch above zero	169·12
	Pressure on piston of 1st cylinder at the end of its stroke, in pounds per square inch above zero	91·50
	Mean back pressure against piston of 1st cylinder during its stroke, in pounds per square inch above zero	45·95
	Back pressure against piston of 1st cylinder at commencement of its stroke, in pounds per square inch above zero	39·57
	Indicated pressure on piston of 1st cylinder, in pounds per square inch	110·98
	Net pressure on piston of 1st cylinder, in pounds per square inch	108·98
	Total pressure on piston of 1st cylinder, in pounds per square inch above zero	156·93
Steam Pressures in 2nd Cylinder per Indicator.	Pressure on piston of 2nd cylinder at commencement of its stroke, in pounds per square inch above zero	60·60
	Pressure on piston of 2nd cylinder at the end of its stroke, in pounds per square inch above zero	31·30
	Mean back pressure against piston of 2nd cylinder during its stroke, in pounds per square inch above zero	31·06
	Back pressure against piston of 2nd cylinder at commencement of its stroke, in pounds per square inch above zero	30·20
	Indicated pressure on piston of 2nd cylinder, in pounds per square inch	10·537
	Net pressure on piston of 2nd cylinder, in pounds per square inch	8·537
	Total pressure on piston of 2nd cylinder, in pounds per square inch above zero	41·597
Steam Pressures on 3rd Cylinder per Indicator.	Pressure on piston of 3rd cylinder at commencement of its stroke, in pounds per square inch above zero	27·71
	Pressure on piston of 3rd cylinder at the point of cutting off the steam, in pounds per square inch above zero	22·28
	Pressure on piston of 3rd cylinder at the end of its stroke, in pounds per square inch above zero	9·55
	Mean back pressure against piston of 3rd cylinder during its stroke, in pounds per square inch above zero	4·21
	Back pressure against piston of 3rd cylinder at commencement of its stroke, in pounds per square inch above zero	3·74
	Indicated pressure on piston of 3rd cylinder, in pounds per square inch	12·457
	Net pressure on piston of 3rd cylinder, in pounds per square inch	10·457
	Total pressure on piston of 3rd cylinder, in pounds per square inch above zero	16·667
Boiler Vapourization.	No. of pounds of water that would have been vapourized in the boiler had the feed water been supplied at the temperature of 100 degrees, and vapourized under the atmospheric pressure of 29·92 inches of mercury	36509·6289
	No. of pounds of water that would have been vapourized in the boiler had the feed water been supplied at the temperature of 212 degrees, and vapourized under the atmospheric pressure of 29·92 inches of mercury	40775·4371
	Pounds of water vapourized from 100° Fahrenheit by one pound of coal	8·2976
	Pounds of water vapourized from 100° Fahrenheit by one pound of combustible	10·0744
	Pounds of water vapourized from 212° Fahrenheit by one pound of coal	9·2671
	Pounds of water vapourized from 212° Fahrenheit by one pound of combustible	11·2515

(*To be continued.*)

To the Directors of the Perkins Engine Company, Limited.

GENTLEMEN :—In accordance with your desire, as communicated through Mr. Loftus Perkins, I, on Saturday the 22nd May, made a trial of the Perkins patent engine fitted on board the screw steam yacht *Anthracite*, preparatory to her leaving England on her voyage to New York.

You are of course perfectly well aware of the nature of the engines and boilers of the *Anthracite*, but in order that this report may be more readily followed, I think it well to state, in the report itself, the leading particulars of the machinery of that vessel.

The engines are of the direct-acting inverted type with surface condensation. Two cylinders only are used, but the after cylinder has two diameters of bore; the upper and smaller one is the high pressure, and receives the steam from the boiler during the first half of the down stroke, the lower and larger diameter, is the medium or intermediate, and is supplied at the up stroke with the steam, which in the high pressure did the work of the preceding down stroke. The exhaust from the bottom of the after cylinder passes into a chamber, from which is afforded the supply to the low pressure (the forward) cylinder, and from this arrangement there is obtained in two cylinders an expansion of thirty-two times.

The distribution of the steam in the after cylinder is made by three lifting double-beat valves, the upper faces of these valves being, however, divided into two sections. The valve stalks rise and fall by the action of eccentrics, which control the motion of the stalks downward as well as upwards, the stalks being loose in close-topped sockets in the valves, so that after the valves are seated the stalks can recede from them. The distribution of the steam to the low pressure cylinder is made by an ordinary slide valve with an expansion valve on its back; this latter valve is worked off the prolongation upwards of the circulating pump rod. The surface condenser is composed of a number of close-topped, galvanized, wrought-iron tubes, standing vertically from a tube plate, and having within them smaller tubes open at both ends, and proceeding upward from a lower tube plate, so that the water from the sea passes up through the central tubes, and down the annular spaces to the inlet of the circulating pump.

The exhaust steam is admitted into the body of the condenser, and comes into contact with the exterior of the close-topped tubes, the condensed steam being drawn off by the air-pump, and returned to the hot well which surrounds the upper part of the condenser. The space between the high pressure piston and the upper side of the intermediate piston is in connection with the chamber which supplies the low pressure cylinder. The circulating pump is worked by a beam off the low pressure piston rod, and the air-pump is worked by a similar beam off the intermediate cylinder piston rod. The feed pumps and bilge pumps are worked off the cross heads of the circulating pump and of the air-pump. The reversal is effected by a link motion.

The cylinders and their covers are heated by steam circulating through wrought-iron pipes cast into the thickness of the metal, and are very efficiently clothed so as to prevent loss of heat.

The boiler is the well known Perkins boiler formed of successive horizontal rows of wrought tubes (3 inches external diameter) connected at frequent intervals by vertical thimbles, the whole series being contained in a wrought-iron double casing having the space filled in with vegetable black. The water gauges, one in the boiler and one in the engine room, are made of flat plates of mica secured in frames. The boiler is supplied with distilled fresh water. There is a still fitted with a coil, and having its steam pipe in connection with the condenser, by which the store of water can be distilled over for use.

With respect to the dimensions of the engine, I was furnished at my request by Messrs. Hawks, Crawshay & Sons, the builders of the engines, with the working drawings. These drawings show the high pressure cylinder to be 8 in. bore, the intermediate 16 in. bore, and the low pressure 23 in. bore, but I was informed by Mr. Perkins that the cylinders were all somewhat smaller than the foregoing dimensions. He has now sent me the gauges, and these give the high pressure cylinder at $7\frac{3}{4}$ in. diameter, the intermediate as $15\frac{13}{16}$ in., and the low pressure as $22\frac{13}{16}$ in. The stroke in both cylinders is 1 ft. 3 in. The diameter of the piston rods (the areas of which have to be deducted from the area of the intermediate piston, and from that of the underside of the low pressure piston) is $2\frac{3}{4}$ in.

My principal assistant was on board the *Anthracite* on the Friday, and he informed me that the fire was let out at about 2.30 p.m. on that day, and as the result the boiler and water were practically cold when the fire was lit on Saturday morning.

Preparations for the trial had been made by weighing out 50 cwt. of "Nixon's navigation hand-picked lumps" into fifty 1 cwt. sacks. These were ranged on deck. The bunkers, which were full, were sealed up both above and below. A spring balance was hung up on deck, close to the stokehold hatch, and one of my assistants caused each sack of coal to be reweighed just before it was lowered for use. The gross weight was taken, and the sacks were afterwards separately weighed so as to obtain the net weight of the coal.

Fifty pounds of dry wood were served out and two sacks of coal, and with these the fire was laid (the grate has an area of about 15 square ft.). The fire was lit at 6.28 a.m. Steam was up and the engines were turned round at 7.18 a.m. The height of water in the boiler gauge was noted, and also the height in the hot well, the still cock being shut, was sealed in that position. The steam stop valve was sealed in its wide open position. The engines were started, and the vessel got under way at 7.20 a.m. The throttle valve was put into the position which the engineer knew, from experience, would cause the engines to run at about 130 revolutions per minute after they became thoroughly heated up, and the handle was sealed into this position, the link motion being in full gear ahead. The engines were provided with a Harding's counter, such as is used in the Navy, and there were pressure gauges to show the boiler pressure, and the pressure in the chamber supplying the low pressure cylinder, and the condenser was provided with a vacuum gauge. Four Richard's indicators were fitted, viz.: one to the high pressure end of the after cylinder, one to the intermediate end of that cylinder, one to the top and one to the bottom of the forward, the low pressure cylinder.

The first set of diagrams was taken at 8.22 a.m. The first reading of the counter at 8.30 a.m. From this time until 5.45 p.m. the counter was read at the hours and half hours, and sets of diagrams were taken at the quarter past the hour, and at the quarter to the hour. The time when each sack of coal was lowered into the stokehold was noted, and also the time when the stoker commenced to use the contents of each sack.

The last shovelful of the fifteenth sack was put on at 5.18 p.m., and it was decided to stop the trial as soon as the coal then in the fire was exhausted.

I determined to let the engines run on until they stopped of themselves, and to take indicator diagrams, first at each quarter of an hour and then at each five minutes during the time they were gradually stopping. The quarter hour diagrams were taken until 6.30 p.m., when the engines were making 124 revolutions, and the five minutes diagrams were taken until the engines came to a stand at 7.23 p.m. or 12 hours 3 minutes after their start in the morning. The water in the boiler was pumped to the same level in the gauge as that at which it had stood in the morning and the height of water in the hot well was noted.

The mean revolutions from 8.30 a.m. to 6.30 p.m., 10 hours, were 130·77 per minute, and from the first start to the same time being 11 hours 10 minutes, the mean revolutions were 130·4 per minute.

An experiment was made as to the transmission of heat through the boiler casing. This was carried out by placing the bulb of a thermometer in contact with the top of the casing, the bulb being covered over with cotton waste; the result was that at the end of one hour the thermometer stood at 125 degrees Fahr.

From the start at 7.20 a.m. to 6.30 p.m., 11 hours and 10 minutes, the engines developed an average gross indicated horse-power of 80·55, but from 6.30 to the time, 7 23 p.m., that the engines stopped of themselves from the fire having burnt itself out, the power was of course gradually diminishing. This being so I have calculated the whole work from first to last in foot-pounds; these amount to 1,828,291,466 foot-pounds, equivalent to 923·38 horse-power if exerted for one hour.

I estimate the 50 pounds of wood as of about one-third the value of coal as fuel, say ...	17 lbs.
The coal 15 cwt.	1680 „
	1697 „

The gross indicated horse-power developed during the trial being equivalent to 923·38 horse-power exerted for an hour 1697 ÷ 923.38 = 1·83 pounds of coal per horse-power per hour, *including the coal used in getting up steam.*

As a check upon the foregoing from the time when the first shovelful of the fourth sack of coals was put on the fire, namely, at 7.50 a.m. to the time when the first shovelful of the fifteenth sack of coals was put on the fire, namely, at 4.45 p.m., *i.e.*, 8 hours 55 minutes, the engines exerted an average of 80·9 horse-power; this gives the consumption per horse-power per hour at 1·7 pounds, assuming the fire was uniform at the commencement and end of these times. The loss of water for the whole 12 hours was $23\frac{1}{3}$ gallons.

The engines worked with the most remarkable smoothness and regularity, as with the exception of tightening up the bolts of two glands about an hour after the start, there was not a spanner or hammer or any tool used about the engines during the 12 hours the ship was under way, nor was there a single handle connected with the engines shifted. The link-motion was in full gear the whole while, and the stop valve and throttle valve remained, as I have said, sealed up and unmoved.

Water was allowed to circulate on the thrust-block, but there was not a heated bearing anywhere. The amount of lubrication was small, involving an expenditure of about one gallon of lard oil, while cylinder and slide lubrications are in the Perkins system inadmissable and with the metal used unnecessary.

The engines were thoroughly steady, no straining or racking of any kind, in fact it is impossible for any pair of engines to have worked in a more thoroughly satisfactory manner, so far as all external evidence of working was concerned, and there were no sounds to lead to any other belief than that of all being satisfactory within.

I hope on the return of the *Anthracite* from America to have an opportunity of seeing the engines opened, and of thus observing their condition after some thousands of miles of steaming, and I should also be glad to have an opportunity of retesting the consumption.

At the conclusion of the trial my assistants took away the four indicators and the spring balance with which the coals were weighed. All these have been tested with the result that the balance and the 100 pound spring (used in the high-pressure cylinder indicators) and some of the lighter springs, are absolutely accuate, and that the variations in the others are too trifling to call for any allowance in calculating the mean pressures.

It may be well to state that the mean pressures of the various diagrams (of which there were 128 in all) have been ascertained by dividing the areas of the diagrams, obtained with the planimeter, by the lengths of the diagrams. This is a thoroughly accurate mode, while the plan commonly followed of measuring the heights of the diagrams at a number (usually ten) of places is one which ordinarily gives a pressure in excess of the truth.

It would be an investigation of considerable interest in an engineering point of view if a vessel fitted with first-rate compound engines of the ordinary construction, and working, say, at 70 pounds pressure in the boiler and indicating something about the same power as those of the *Anthracite*, viz., from 70 to 90 horse-power, could be tried in a precisely similar manner to that in which the *Anthracite* was tried.

In conclusion, I wish to say that I esteem myself particularly fortunate in having obtained the friendly co-operation during the run of Mr. William Rich, of Messrs. Eastons & Anderson, whose long experience in engine trials rendered his assistance of the greatest value, and to whom I beg leave to express my best thanks. I have his authority for saying that he entirely concurs in this letter of report.

I am, gentlemen, your obedient servant,
(Signed) F. J. BRAMWELL.

THE programme of the meetings of the Institution of Naval Architects, which takes place on the 6th, 7th, and 8th of April, is lengthy and varied. There will be no less than sixteen papers on the theory and practice of naval architecture and on marine engineering. There are to be four papers on a subject which is exciting much attention, viz., the use of mild steel in substitution for iron as a material for the construction of the hulls and armour of ships, the shells of steel boilers, and parts of the machinery. Mr. Samuda will deal with the application of steel to the construction of war ships. Mr. W. Parker, chief engineering surveyor to Lloyd's Registry, will treat on the failure of the original steel plates used in the boilers of the *Livadia*. The best steel has occasionally behaved most treacherously, and Mr. Parker's paper is expected to throw considerable light on this subject. The third paper on steel is by a well-known French authority, M. Berrier Fontaine, who will give an account of the experience of the French dockyards in the use of mild steel for shipbuilding. The fourth paper is by Mr. J. R. Ravenhill, on the increasing use of steel for shipbuilding and marine engineering. Of the papers on theoretical naval architecture Mr. W. H. White, of the Admiralty, will contribute two. Mr. R. E. Froude will deal with a subject with which his late father's name was identified, viz., the leading phenomena of of the wave-making resistance of ships. Finally, Mr. W. John, of Lloyd's Registry, will read a paper on grain cargoes, a matter to which the loss of many grain-laden vessels gives a painful interest.

ROCKET LIFE-SAVING APPARATUS.

THE last report of the Chief of Ordnance to the United States Government contains, amongst a vast amount of interesting matter, a valuable report by Lieutenant Lyle on life-saving rockets, based on a series of experiments carried out at Sandy Hook last year, with a number of Russian, German, and English apparatus. The Russian rocket consists of an iron cylindrical case 3 in. internal diameter and 27.2 in. long, closed at the head by a hemispherical metallic cover, and at the rear with an iron plate provided with a screwed socket and a series of small vent holes. The stick is of light wood, 27 in. long, with a screwed head for attaching to the rocket body, and near the opposite end on the under side is a light steel hook for engaging in the chain when the rocket is fired. The total weight of the apparatus is 25.5 lb. The firing tube is rectangular in section, about 50 in. long, and formed of thin sheet iron, bent so as to have on the lower side two parallel flanges or projections in such a manner that the tube has a slot running along the whole length of the tube on one side, except for a few inches at the rear end where it is strengthened. This tube is mounted on a graduated quadrant placed on a tripod. On being fired the hook on the underside of the rocket-stick slides in the groove just mentioned, and in emerging engages in the end of a short chain hung outside the muzzle of the tube. This chain is connected to the safety line.

There are two descriptions of German rockets, one resembling in general appearance the Russian rocket just described. It is made in two sizes, and consists of an iron cylindrical case fitted with a solid ogival head, the butt end of which fits within the case, and is fastened to it by screws. The rear end of the case is reinforced by an internal ring and an open casting is also screwed to it; this casting, which extends about 8 in. to the rear of the case, is cylindrical, but with the metal cut away except at the ends, which are connected by three ribs, parallel axially and converging to the rear end, which contains a socket for the stick to be screwed into. The latter is of wood, coned at the front end and covered with sheet iron, a screw being introduced for attaching it to the case, and the rear end is provided with an iron loop through which the chain is passed. The following are the dimensions of the leading parts of the 2 in. and 3 in. rockets of this class:

	2 in. Diameter. in.	3 in. Diameter. in.
Body:		
Total length of rocket	23·5	34·5
Length of case	15	
Inside diameter	2·05	3·1
Thickness of case	·05	·06
Length of head	5·2	8·75
„ base ring	1·1	1·35
Total length of base	5·8	8·3
Number of ribs	3	3
Stick:		
Total length	39·4	39·9
Largest diameter	2·2	2·3
Smallest „	2·0	2·0
Length of chain	87·	122·5
Weight of rocket complete	15·5 lb.	42·25 lb.

The German anchor rocket is very similar in general form to those just described. Instead, however, of the head being ogival it is formed with four short arms and flukes; the base piece is tripoidal and not cylindrical, but is made with three ribs and open spaces between them, and the stick is of thin sheet metal formed into a tube about 2·3 in. in diameter. The German rocket stand consists of an open sheet iron trough 12 ft. 9 in. long, and trapezoidal in form with a rounded bottom, in which at the front end a slot 1 in. wide and 10·9 in. long is formed for the chain to pass through. The upper edges of the trough are stiffened with angle-iron, and along the bottom from the slot before mentioned to 10 in. beyond the rear end of the trough, a stiffening plate is bolted. To the projecting extremity of this bar two small inclined stays are attached. The stand is supported by two inged legs near the front end of the trough, and by the projecting bar at the rear end, which rests on the ground. The rocket is ignited by a percussion snap lock.

The English Boxer rocket differs from any of the former already described. The body is made of two Bessemer steel cylinders placed end to end in the same axial line. Both cylinders are charged with composition in such a way as to leave in each a conical cavity which reaches to within four inch of the forward ends of each case these ends being filled in solid with composition. The front end of the forward case is closed with a semicircular metal head, and the rear ends of each with a ring, leaving a circular opening one inch in diameter in the centre. The two cases are secured together by screws passing through a diaphragm with a central opening, and placed between the front of one cylinder and the rear of the other. Metal straps pass round the cases, and are extended on one side to receive the stick, which are of pine, nine feet six inches long, one-and-a-quarter inch square, and protected beneath the vent of the case by a sheathing of tinned iron. Holes are made in each, and axially for some distance, and then curved till they pass through the stick for the reception of the line. The stand is of sheet iron, except the legs, which are of wood, and is something like the German form. The Boxer fuses are conical, one-and-a-half inches long and one inch in the largest diameter, to fit the opening in the vent. The object of forming the body of this rocket in two parts is to give it additional range, the charge in the forward case igniting only after that in the rear case has burnt out.

Finally, we may mention the Hooper rocket, a metallic cylinder 3.75 inches in diameter and fourteen-and-a-half inches long, closed at one end by a spiral wooden head and at the other by a metal base extending several inches beyond the rear of the case, and furnished with a number of spiral springs through which the gases escape and impart a rotary movement to the rocket. No stick is attached to this apparatus and the chain is linked to a swivel on the base.

By way of comparison, we may notice one form of life apparatus in use in America. This is a solid shot, twelve inches long and two-and-a-half inches in diameter, with an ogival head. The base is recessed and tapped, and into it is screwed a hollow cap. To flanges on the rear of this cap are pinned five arms or flukes 83 inches long and 25 inches thick. These are connected by rigid horizontal arms, at a point two inches below that where they are pinned to the cap, to a central bar thirteen inches long and about five-eighth inches diameter; one end of this bar is made with an eye, and the other end is screwed and a nut is placed on it. This nut slides in a part of the opening within the cap, the diameter of the remainder being only sufficient to allow the passage of the bar, except in one place where it is slotted out to receive a locking spring. When the flukes are closed around the central bar, the nut on the end of the latter is pressed inwards, but when the flukes are opened, the nut and bar move forward until the former is stopped by the shoulder in the cap, and at the same time the spring-catch before mentioned locks the flukes open. This projectile is fired from a gun having a bore two-and-a-half inches in diameter and twenty inches long; it is placed in the gun point downward, with the flukes closed; but after being fired the shot reverses, and the pull from the rope fastened to the eye at the end of the central bar drives back the latter, opening the flukes until they are locked in their extended position.

The result of a large number of experiments made with the Russian, German, and English systems of rockets are given in Lieutenant Lyle's report, and the conclusions he draws from them may be summarised as follows. He found that the Russian rockets were extremely unwieldly, and that they and the stand were very inconvenient to handle. The mode of picking up the chain at the commencement of the flight is objectionable, as a sudden strain is thrown upon the chain, sufficient sometimes to break it. The construction was very faulty, and many of the rockets failed through blowing out the base, which is weakened by a large number of vent holes. The range and accuracy obtained left much to be desired. The German rockets gave excellent results in both the latter respects, moreover none of them failed, and the workmanship was extremely good; the stand also left nothing to be desired. The drawback to the system is its costliness; the smaller-sized rockets cost about 15s. each, the large size about 23s., and the anchor rockets nearly £5. Nevertheless these rockets are preferred on the New Jersey coast to any other, although the confidence in them is not sufficiently great to encourage the men to stand near when they are fired. The Boxer rocket is reputed to be erractic in its flight, and very easily deviated from its course by wind; it is also considered too complicated for use on the American coast. The Hooper rockets are stated to have failed very badly, and to be liable to explode dangerously. Lieutenant Lyle concludes his report by pointing out that the greatest possible care is required in packing, storing, and handling rockets; the composition is very liable to get loose from the case, and when fired gases find their way into the spaces thus left, often producing an explosion. Under the most favourable circumstances "it may be said that with rockets one never knows what may happen, nor where they will go when fired."—*Engineering.*

IMPROVED BOAT LOWERING APPARATUS.

THERE has been so much agitation about efficient means for lowering boats safely at sea, that it is to be expected that some means will be eventually and generally adopted. We illustrate herewith a boat lowering apparatus, the property of the British and Foreign Boat Lowering Company, Limited, 5, Austin Friars, Old Broad Street, which seems to have many valuable features to fulfil all the requirements of the investigating committee on the accident to H. M.'s steam frigate *Ariadne*. In their report the following requirements and qualifications for an efficient apparatus were recommended.

1. The arrangements should be of the most simple character, and readily understood by untrained men.

2. The apparatus should be always in readiness for immediate use.

3. The lowering and disengaging gear should be certain in their action and under the absolute control of one man.

4. It should be possible to lower both ends of the boat simultaneously.

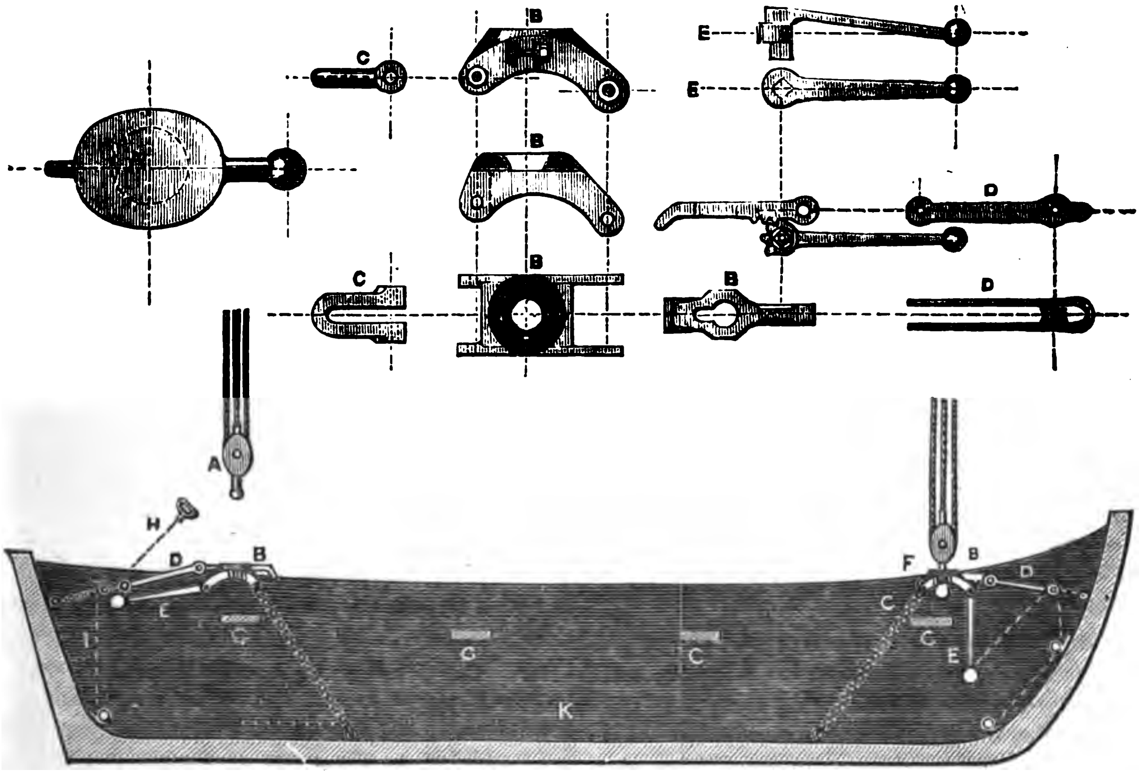
5. The disengaging operation should be easily and quickly performed.

6. There should be no risk of fouling, nor of the persons in the boat being injured by the falling of the heavy gear.

7. The lowering gear should be in conjunction with the hoisting pendants, or easily and quickly attached to them.

All these points are amply fulfilled by the Company's Patent gear, and at the same time, as all the improvements are added in the boats and to the block on the falls, the usual falls and davits require no alteration. This is a great consideration in applying a new improvement, as the first cost is thereby considerably reduced and the shipowner sees that if not satisfied he has but to remove the new gear and his old tackle is as good as ever.

In reference to the illustration the forward fall is shown locked and secure, and the after fall is disengaged. The peculiarity of the fall block is that it terminates in a nob, not in a hook. This is a great advantage in a rough sea as such accidents frequently occur by the catching of the hook in the thwarts, chains, or persons of those on board. The difficulty of releasing a hook at any moment is very great when the boat is unsteady and is alternately light and bearing hard on the hook. The nob of the bolt attached to the block A passes through a circular collar B, through which passes a slotted bolt B. The slot in this bolt is as small in one part as the shank of the ball block, and in another part sufficiently large to let



IMPROVED BOAT LOWERING APPARATUS.

the nob pass through it. In small boats the chain-slings are arranged (as shown in the drawing) so that the weight of the boat assists in locking the ball-block. In heavy boats both chains are fixed to the frame of the machine, and when fixed for hoisting the sliding bolt is fixed to the box by means of a pin passing through both.

Where practicable, the simplest plan is to fix the machine under a thwart and bolted to the keel, this doing away with all sling-chains. This bolt is provided with teeth as a rack, into which gears a partly toothed pinion on the end of the ball lever E. When the ball lever is hanging down, as at the forward end of the boat, the bolt locks the ball block, but as soon as the ball lever is raised as seen aft, the bolt B is thrust forcibly forward, and the ball block is allowed to escape. The raising of these ball levers can be effected simultaneously by one man sitting at the stern by means of the running chain K and the handles H and I, or either block can be released as desired.

The picking up of the boat is very easy by taking in one hand the block and lifting up with the other the ball lever, slipping the ball block into the opening and dropping the lever. This operation is performed instantaneously, and when locked it is impossible for any rising or falling of the boat to disengage the ball block and fall. But at the same time the man locking the ball can instantaneously release it if he finds the man at the other end of the boat has failed to lock; thus preventing the boat being left hanging end on by a receding wave.

Another great advantage of the ball block above hooks of any kind is that in case of any foul of the fall ropes whilst hoisting, the nob of the ball block will turn in its socket, and thus relieve the twist or foul.

The gear can be fixed or removed immediately by inserting or removing the pins at the foot of the stay rods and fixing or unhooking the sling chains.

They have just fitted the boats of the *Garth Castle*. On March 26th their gear was tried before a good company, and under the personal superintendence and orders of the captain (Captain Webster), with great success. Captain Small (Messrs. D. Currie & Co.'s superintending captain) was also present. On one occasion the boat was let off about 4 feet from the water, with six men in her, and also oars, sails, two barrels water, &c., the gear acted splendidly. Messrs. Scrutton & Co., who are manufacturing for the Company was present, and all seemed pleased at the results acheived.

IMPROVED FOG HORN.

As the danger to vessels during fogs is by no mean on the decrease any apparatus that promises additional security well deserves the consideration of our readers.

The horn is one of the best means of giving a distinct warning sound during the continuance of a fog. We consider a horn better than a bell, as it gives a definite direction to the sound. A bell gives a sound equally in every direction, and does not thus convey the distinct idea of position produced by the blast of a horn, which proceeds only in one direction. In sailing vessels where there is no steam on board it is impossible easily to produce a fog horn signal. The apparatus we illustrate is a simple mechanical means of producing a blast through a horn. The trumpet A is of the usual form, and at the larger end is provided a conical disperser, sustained in place by radial arms. The smaller end of the trumpet is inserted in the chamber C, and is provided with a reed B.

The chamber C communicates with the air cylinder F, whose piston is moved by means of a handle at the end of the piston-rod, projecting from a stuffing box at the end of the cylinder. Air enters at either end of the cylinder through valves 6, and is forced through a passage containing a check valve into the air chamber C.

The resulting blast is clear and sonorous, and the apparatus thus appears very efficient for sailing vessels.

THE MAMMOTH FIRE BOAT.

A very large proportion, fully one-half of the whole number of fires in New York and Brooklyn occur at the river side. As most of the buildings there are of excessive height it has been found that the ordinary fire appliances are quite unable to cope with the fires. A gigantic fire boat has been designed for this purpose by a Mr. Maxim, of sufficiently large power to flood out and almost instantly extinguish any fire that could possibly occur. This would no doubt prove a very remunerative outlay, although the cost will be large, in the great amount of salvage thus saved.

The boat is of iron, 250 ft. long and 40 ft. beam. She is driven by paddle-wheels, which have each their independent engines, so that the boat can turn as it were on a pivot. She carries 3,000 horse-power, all of which can be turned on to her paddle power or on to the pumping engines. The engines are compound, using steam at 80 lb. pressure per square inch. The pumps are of the compound duplex pattern, and are of great size and strength.

The novel features of this boat consist of the vertical stand pipe and the two discharge pipes mounted on trunnions on the stand pipe, one at the top and one at the bottom. The stand pipe communicates with the water pressure reservoir below deck, and will rotate in any direction, and will elongate or shorten by a telescopic joint.

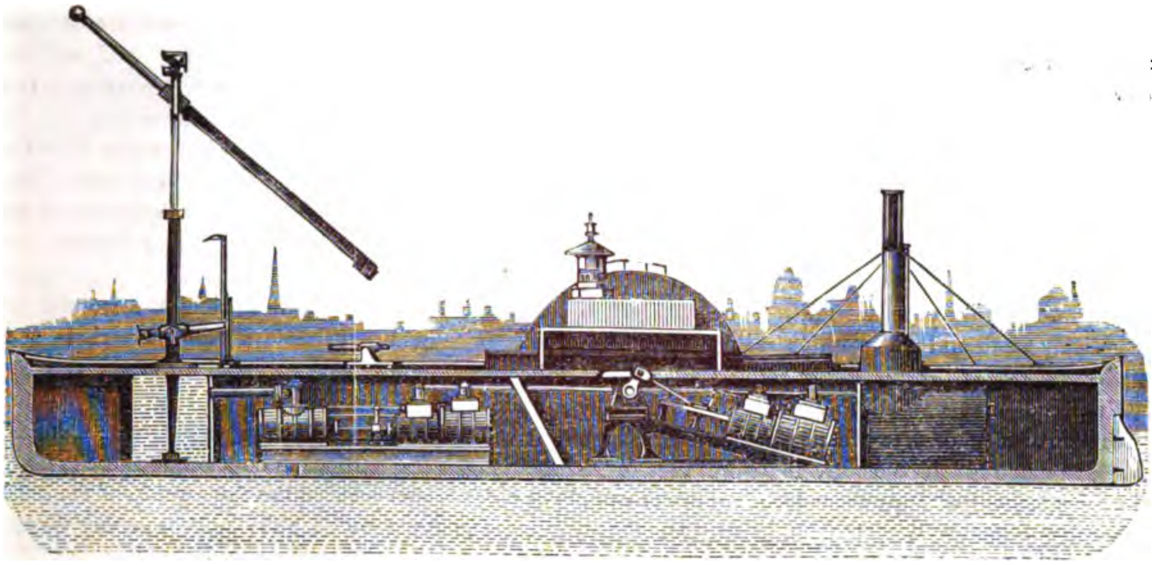
The lower discharge pipe is designed to extinguish fires on shipboard or for sinking a ship. It has a nozzle 20 in. diameter, and can therefore throw a stream 400 times greater than that of an ordinary 1 inch fire nozzle.

With the sea for a supply and 3,000 horse-power on the pumps, the stream would be that of a considerable waterfall of inconceivable force and magnitude. In the case of the upper nozzle the discharge is 60 ft. above the deck, and the nozzle is 60 ft. long from the trunnion. When at its highest angle of elevation the nozzle is 100 feet above the deck.

A very ingenious modification is used on the upper discharge pipe. A series of nozzles, five in number, varying in diameter from 6 to 10 in. are arranged in a rotating barrel like a revolver, and thus any variation in the size of the nozzle for short or long distances can be produced instantaneously without stopping the flow. In addition to the water appliances this boat carries a gun to demolish the walls of buildings when the fire cannot otherwise be got at. This gun is of special construction, 16 in. in the bore, firing a wooden projectile 4 ft. long.

THE NAVY ESTIMATES.

On Friday night Mr. Trevelyan moved the Navy estimates in a speech at once complete, modest, and lucid. It evoked very little criticism, although the sums for which Mr. Trevelyan asked are very large. Nor, indeed, is it easy to criticize a scheme which is in almost all respects admirable. Up to the present it has been constantly charged against Liberal Governments that they are invariably the reverse of liberal in dealing with the Navy; and that when they go out of office they leave the ships of which they have had the care in a miserable and dilapidated condition. It would seem from Mr. Trevelyan's speech that this objectionable charge cannot for the present at least, be brought against Mr. Gladstone's Administration. Not only does the present Board of Admiralty approve of what was done by its predecessors, but it goes further in the same direction, and announces that the Navy of England must be supreme, and that supremacy can only be obtained by taking advantage of all the aid that science can lend We are to have everything that is new provided it be



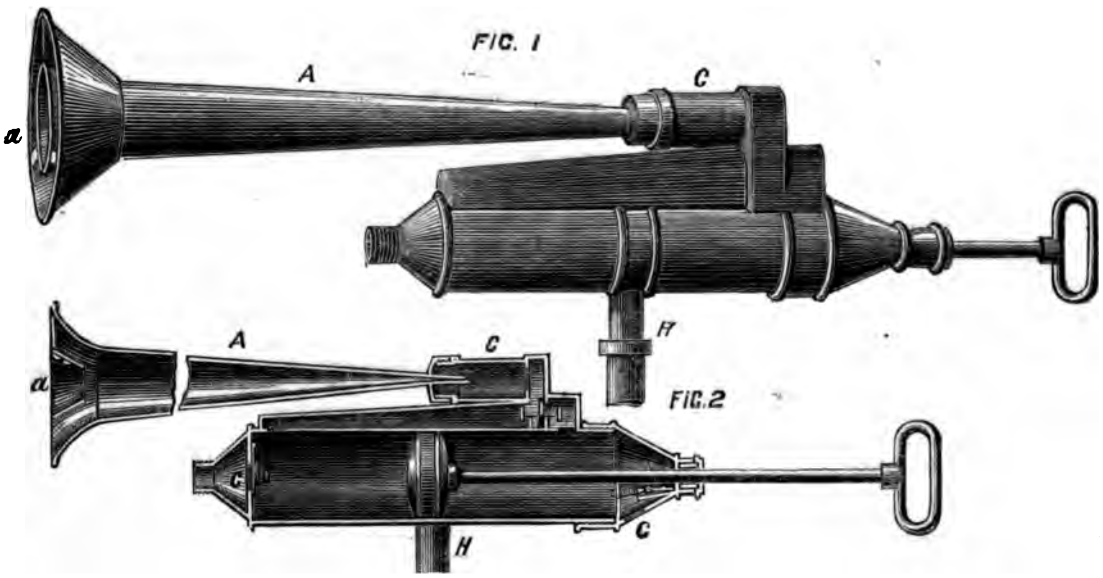
THE MAMMOTH FIRE BOAT (*see page* 12).

also good. Steel armour, breech loading guns, torpedoes, torpedo boats, machine guns, and electric lights are all to be pressed into the service of the Navy. The price to be paid will be high; but omelettes cannot be made without breaking eggs. The old estimate for first rates was £1,000 a gun. Thus the cost of the *Duke of Wellington* the last of the great three-deckers which have made England's flag glorious, including her machinery, did not exceed £150,000. In the present day we cannot get an ironclad fit to fight in line of battle for less than £400,000, and the price of such ships as the *Inflexible* far exceeds that sum. The Italians spend nearly a million on each of such ships as the *Duilio* and the *Lepanto*. To argue that the sums thus laid out in Great Britain are wasted, is to show that the questions at issue have not been fully grasped. Not less than one-half the whole mercantile marine of the world sails under the British flag, and relies for protection on British ships of war. Under the circumstances it is important that our Navy should be of adequate power. Money spent in rendering our merchant ships safe from pillage could not be regarded as wasted under any circumstances, so long as its expenditure secured the required end. But wholly apart from this consideration is another, which may well deprive the Navy estimates of their terrors. When we spend half a million on an ironclad, we really, as a nation, do not lose the money. John Bull takes it out of one pocket and puts it into another. To cite armour-plates as an example. In their production quite a small army of men is employed in raising coal, smelting iron, making bricks, and, finally, in producing the plates themselves. The construction of armour-plate mills and furnaces gives employment to yet other workers by the score. In making guns and ammunition Woolwich Arsenal keeps over 7000 hands employed, and in time of pressure as many as 13,000. In our dockyards thousands of men earn their living. Our engine builders, when they get orders from the Admiralty, are delighted. Not one sixpence need be spent out of Great Britain, which is absolutely self-sufficing in the matter of war-ships. Abroad it is different. France, Germany, Italy, have all to come to us for armour-plates, at least, and for much else besides. It may be urged that if we did not spend half a million on a ship, we could save that amount in taxes, which would do us more good. Perhaps the saving would amount to about 3½d. per head of the population, or in a family of seven to, say, two shillings, an appreciable sum; one as nothing compared to the advantages accruing to many hundreds of artisans employed in the construction of our navy. A modern English ironclad is not, therefore, as some would have us think, an embodiment of waste. There is more to be urged in her favour than the bald statement that, whether she does or does not represent money misspent, she is indispensable.

Those portions of Mr. Trevelyan's speech possessing most interest for our readers refer to three subjects, namely, the construction of new ships; the adoption of breech-loading guns in the Navy; and the pay and position of naval engineers. The programme of the

Admiralty for the coming year is easily stated. The *Agamemnon* and *Ajax* are to be completed for sea at Chatham; the *Inflexible* is to be commissioned in June or July; the *Conqueror*, an improved Rupert, is to be pushed on; the *Polyphemus* is to be completed; the *Colossus* and the *Majestic* will each be advanced about a quarter; the *Collingwood* will also have work done on her. So much for what may be termed old ships. The most noteworthy feature in the Admiralty scheme is the construction of ships of a new type. These will be partially-armoured cruisers, intended to cope with the second-class ironclads of other Powers, and to protect our commerce all over the world. Time was when comparatively small and cheap ships would have been deemed sufficient for the purpose. Sir E. J. Reed—then Mr. Reed—was carried to fame and fortune by designing small men of war which should have a high speed. He made his ships short, therefore they were small and handy. Making them speedy was the affair of the marine engineer, and Messrs. Penn, Maudslay, Ravenhill, Rennie, and others, gave Mr. Reed what he wanted. But the day of Bellerophon's is over, and the small ship of the epoch is described by Mr. Trevelyan in the following passage:—"Her length is to be 315 feet; her extreme breadth 61 feet; and her tonnage about 7,300. Her horse-power 8,000; her bunkers will hold 900 tons; and her speed on the measured mile will be sixteen knots. She has the great advantage of twin screws. She will have a belt 8 feet broad and 140 feet long amidships, of steel-faced armour, 10 inches thick with 10 inches of backing, protecting her engine-room and boilers 3 feet above water and 5 feet below. She will have a conning tower of steel-faced armour; a protecting deck of inclined steel, 3 in. thick, 5 ft. under water, covering the whole of that part of the ship, both fore and aft, which is not clad in iron. She will carry an armament of four 18-ton 9·2 inch breach-loading guns, mounted in barbettes, with protection against bullets, which at a thousand yards will pierce 16½ inches of iron armour, and more than 13 inches of steel-faced armour. She will carry likewise six 6-inch breech-loading guns, equal in range to those which carried desolation at a distance of five miles into the Peruvian harbours; she will be equipped with boat guns, torpedoes, machine guns, and will probably be fitted with a couple of torpedo boats in addition; and she will have room for over 400 men and officers to work her and fight her. She will combine the speed of the *Leander* with guns of greater power than the *Thunderer* or the *Devastation;* and the Admiralty with some confidence submit her to the criticism of a nation which thinks little of a vessel that cannot travel far and fast, and fight sharply and long. She will rank high among cruisers, and high among second-class ironclads, and in the hope that she will meet the ends for which she is designed, it is proposed to lay down one such vessel this year at Portsmouth, and another at Chatham. Her hull and engines will cost £400,000, as against £550,000 for the *Collingwood*, and £150,000 for the *Leander*. Later on we propose to confide the construction of another to a private yard. It is impossible within reasonable limits of space to attempt to criticise such a design as this; but we may point out that the adoption of comparatively light guns of enormous power has alone rendered such a ship possible. A comparatively small cruiser of 7000 tons displacement and 8000 horse-power may well excite the wonder of those who once held that the days of big ironclads were numbered. The new ship will hold a rank in the Navy not quite equal to that formerly held by the 74-gun ships. It will not be out of place to give, for the sake of comparison, a few particulars concerning these 74's. One, the *Ajax*, was perhaps the fastest ship of the kind under steam in the Navy after she had been cut down. She was 176 ft. long between perpendiculars, 48 ft. 6½ in. beam, and drew about 23 ft. Her displacement was about 3000 tons. The power of her engines, indicated, 846 horses, and her speed unrigged but ballasted, 7·147 knots. The *Blenheim*, another 74 cut down, was of nearly similar dimensions, and rigged and fully equipped for sea, had under steam a speed of 5·81 knots, obtained with 811 indicated horse power. It is not thirty years since these ships were regarded as powerful vessels, fit to go anywhere and fight anything afloat.

The Admiralty have finally, and we think prudently, determined to adopt breech-loading guns. In the art of constructing such things the world has made great progress within the last fifteen or twenty years; and whereas a 10 in. breech-loading gun, trustworthy and capable of firing a very heavy charge, was an unknown weapon as late as 1871, there can be no doubt now that such a gun can be produced. Comparisons have been drawn between the breech-loading guns of the French navy and our own muzzle-loaders, wholly to the disparagement of the latter. But this is wrong. The French naval breech-loader has already been illustrated in our pages. It is a gun of the past, powerful but in name, and the whole French navy will have to be re-armed ere long; and progress is being made in that direction. The great advantage of breech-loading is that it permits the use of a very long gun on board ships; and great length of bore is essential to give the enormous velocity which can alone enable a comparatively light projectile to get through a great thickness of armour. It used to be a rough rule that the gun must have a diameter equal to the thickness of the plate to be punched; thus a 9 in. gun would punch 9 in. plates, a 12 in. gun 12 in. plates, and so on. But the new 9 in.



IMPROVED FOG HORN *(see page 12).*

gun can punch 16¼ in. of armour at 1000 yards. This is a terrible weapon, and must by no means be taken as representing finality.

We shall make no attempt to follow Mr. Trevelyan through his speech, which all deserves perusal by those interested in the Navy, but proceed at once to deal with the position of engineers in ships of war. Sir E. J. Reed and other speakers all ably advocated their claims to consideration. So far as we understand these claims at present, they are not for augmented pay, but for improved position. Engineers wish for higher rank and more social advantages on board ship. Now we have long and persistently advocated the cause of the engineers in the Navy, and we must not be accused of speaking harshly or unjustly concerning them when we say that they are gradually drifting into a false position, and that much mischief in one shape or another may ultimately be done to their cause by themselves. It is a standing subject of complaint at present, that the modern naval engineer is neither a gentleman nor an engineer; and with limitations, we are compelled to accept the statement as not far removed from the truth. Before going further we must add that there are in the Navy numbers of men who are both engineers and gentlemen in the fullest sense of the words, and these officers will be the first to admit that there are also many men who are neither. The law of the survival of the fittest may come into play, and in process of time the "shovels" will all disappear, and educated gentlemen, quite entitled in every respect to rank with and mess with the other officers, may take their place. Then there will be no more complaints about want of social status. The combatant officers will like the engineers, and will associate with them as their social equals. No possible rule which an Admiralty could frame could bring about this result. What the engineers want they must get for themselves by themselves, and we have no doubt that the new men coming in under the present system and specially educated, will ultimately have nothing to complain of; and that this result is generally anticipated is demonstrated by the apparently growing popularity of the service. "With regard to the engineers," said Mr. Trevelyan, "a great deal has been done. But I think it undesirable that whenever a new Board of Admiralty comes in changes should be looked for. But the Admiralty fully recognizes the change of *status* which is being effected in the case of the engineer. At the same time I think their position is looked upon as a good one, for in 1877 I find that for forty-two posts there were 142 candidates in the engineer's serve; in 1878, 214 candidates for sixty posts. In 1879, forty vacancies attracted 230 candidates; and in 1880 there were 188 candidates for sixty-five posts. As regarded the character of the candidates the right hon. member for South Devon said that they were just the sort of men that were wanted. I do not think, therefore, that at the present time we are justified in raising the pay of the engineers. At the same time we will carefully watch over the interests of that branch of the service, and it is admitted that they deserved somewhat different treatment from what they have hitherto received. There is great difficulty in the question of cabin accommodation, but the recommendations of the committee will be kept in view."

But the whole question can be regarded from another point of view, and much that is now said concerning engineers in the Navy induces us to question whether it is desirable that gentlemen should be employed in the engine rooms of our ships. They may have no cause to complain; but the country may have good reason to wish that gentlemen did not go into the engine rooms. A great deal is said about the responsibility devolving on the engineers of a large ironclad. But just as much and more devolves on the driver of every express train in the kingdom. The value of a fast passenger train with its engine may be taken at a moderate estimate at £10 000, and the whole of this may be lost by a single act of negligence on the part of an engine driver. He has besides many lives depending for safety on him. It would be almost impossible for a naval engineer to do £10,000 worth, or even £1000 worth of damage by negligence—except systematic and protracted negligence —on board an ironclad. The naval engineer has no designing to do. He can alter nothing; he builds no engines; he is not expected to make a suggestion; his use on board ship is to keep the machinery in order, and to do this he must take off his coat and use his hands. Brain work is scarcely needed at all. But gentlemen do not follow handicraft trades; and the work of a naval engineer if it is properly done is the work of a tradesman, and is not professional labour. The engineers know this perfectly well, and the man who works is called by those who do not a "shovel." The new men wear kid gloves and keep their uniforms clean; and to meet this evil and get work done the Admiralty have had to call into existence an entirely new class within the last ten years, namely, the engine-room artificers, on whom, in some ships, devolves all the dirty work, and, in fact, all the work of every kind requiring the use of tools or an oil can. Now this is not as it should be, and we are disposed to think that the country would be much better served by employing thoroughly competent artisans, men who are not afraid of a chisel and hammer, to look after the machinery of our ironclads, than the class now finding its way into our engine-rooms. Each ship ought, however, to carry a superintending engineer, who would, as a matter of course, be an educated, cultivated gentleman. He would have his foremen under him, and would take charge of all the machinery in the ship. His position would be analagous to that of the engineer of any of the large works and factories with which England abounds. No matter what may be said on the subject by those who know little or nothing about it, the charge of marine engines in the Navy is not ennobling, nor exalted, nor intellectual. It involves nothing which calls for the display of talent, and it gives a really clever man no opening whatever.. In the mercantile marine an able man has a hundredfold the opportunity of doing something which will show that he has brains and can use them. Under the circumstances we regard the present system as a mistake, and in this view we are supported by large numbers of engineers who have given the subject their attention.—*Engineer.*

THE ERICSSON "DESTROYER."

SINCE the introduction of the torpedo as an implement of naval warfare, varied and extended improvements have been made towards its perfection, and no one has probably given as much thought and study to the subject as Captain John Ericsson. He has recently produced a projectile which, it is claimed, eclipses all other inventions in that direction, and which he has appropriately named the *Destroyer.* He claims this to be a culmination of his theory which he discussed with Napoleon in 1854. The torpedo boat is said to be peculiarly a Yankee invention, the first ever known being a very primitive model, invented by Captain David Bushnell, of the Engineer Corps, United States Army, and launched in New York harbour in 1776. The torpedo was to be exploded by a clockwork fuse. In 1777 a schooner was destroyed in the harbour of New London, Connecticut, by a drifting percussion torpedo, which was directed against a frigate and missed its mark. In 1807 Robert Fulton experimented with four different torpedoes of his own invention in this harbour with success. Colonel "Sam" Colt, the celebrated arms manufacturer, applied electricity to the ignition of submarine torpedoes in 1843. During the late war of the Rebellion nine ironclads, eleven wooden vessels, and nine transports were destroyed by American torpedoes. Those used on the Danube by the Russians were spar torpedoes, of the same pattern as that used in blowing up the ram Albermarle, on the Albermarle Sound, by Lieutenant William B. Cushing, United States Navy. The Ericsson moveable torpedo was experimented with during the summer and fall of 1875, under the supervision of the inventor's agent, and a full knowledge of the mechanism was obtained.

For the past five years Captain Ericsson has devoted himself to working out the problem of torpedo explosives, and he has succeeded in developing one of such power and vehemence that the very shock would suffice to entirely destroy any war vessel ever constructed. After considerable experimenting, he conceived the idea of substituting gunpowder for compressed air in the propulsion of submarine torpedoes carrying destructive charges of dynamite. His first trials were prosecuted with a projectile of peculiar form and a gun of novel construction, both devised by himself. The greater portion of these experiments, it should be observed, have been carried out with a gun thirty feet long and fifteen inches calibre—not a breech-loader, as in the *Destroyer*, but a muzzle-loader, suspended under the bottom of two wrecking scows, the gun being lifted above the water after each shot by shears and suitable tackle: Several experiments were conducted on the Hudson River, where the water was so shallow that the torpedo invariably sank into mud out of sight, and he was obliged to continue his experiments at Sandy Hook, where the bottom was so hard that he found no difficulty in recovering the torpedo cylinder. The results of the experiments proving so successful, Captain Ericsson has built, at his own expense, a vessel, which he styles the *Destroyer.* This vessel now lies at the Weehawken coal docks, above Hoboken, where experiments have been carried on for a long time, and were concluded on November 11th, the last shot being then fired. The *Destroyer*, to an ordinary observer, would not in the least reveal its mysterious purpose as a most remarkable engine of naval warfare. It is simply an unarmed iron-clad vessel, with bows and stern wedge-shaped, and when ready for action the hull is nearly submerged. The form of the hull is very peculiar, both ends being precisely alike, terminating with very fine wedges, probably sharper than any vessel of deep draught yet built. The length is one hundred and thirty feet, depth eleven feet, extreme breadth of beam twelve feet, thus presenting the unusual proportion of eleven times greater length than beam. The rudder is wholly unconnected with the visible part of the stern, being attached to a vertical wrought iron post, welded to a prolongation of the keel, just aft of the propellor, its upper part being nearly four feet below the water line. The tillers consist of thin plates of iron, rivetted on opposite sides of the rudder, a few inches from the bottom. These tillers are operated by straight rods connected to the pistons of horizontal hydraulic cylinders of five inches diameter, attached to the sides of the keel. Accordingly, the steering gear will be placed ten feet below the water-line, while the top of the rudder only reaches within five feet of the water-line. The leading feature in the construction of the hull is its being provided with an intermediate curved deck, extending from stem to stern, composed of plate-iron strongly ribbed and perfectly water-tight. This intermediate deck sustains a heavy, solid armour-plate, placed transversely to the line of keel, thirty-two feet from the bow, inclined at an angle of forty-five degrees, and supported on the aft side by a wood backing four feet six inches deep at the base. The steering wheel is applied behind this wood backing, a wire rope extending from its barrel to a four-way cock near the stern, by which water pressure is admitted alternately to the hydraulic cylinders at the stern, the motion of whose pistons actuate the rudder. The lower division of the vessel is supplied with air for supplying the boiler furnaces by powerful blowers drawing in air from above. Owing to the peculiar construction of the vessel there is no reason why she would not live at sea in any weather.

Above the intermediate deck is the deck-house or cabin, seventy feet long, composed of plate-iron, and is rivetted watertight to the upper part of the hull. This will be used as the quarters for both officers and crew. The helmsman stands in a pit in the forward end, where he steers the vessel and discharges the gun by a battery. A small glass port, level with his eyes, gives him a view of the course of his vessel and the position of the enemy. He is protected from the fire of the enemy by a wrought-iron invulnerable armour plate, sixteen inches in thickness. A heavy armour plate also protects the base of the smoke stack, so that the entire superstructure and the exposed part of the smoke stack may be shot away, and still the vessel not be disabled.

The forward and after part of the main-deck of the boat is plated with one inch wrought-iron, and on the forward deck is a deflecting armour plate which runs down to the base of the intermediate deck. The gun from which the torpedo is fired is placed on the bottom of the forward part of the vessel next to the keel, the muzzle terminating in the stem seven feet below the water line. The water is prevented from rushing through the gun into the bilge by an outboard valve opened and closed automatically. The small quantity of water rushing into the gun between its discharge and the closing of the valve is run into the bilge after the breech of the gun is opened, and is then pumped out by a steam syphon.

The gun is a smooth-bored cylinder, breech-loading, 30 ft. in length, 16 in. diameter of bore, made of wrought-iron, and hooped with steel. The breech swings upward and over when opened, and when the torpedo and the gunpowder charge is in, it is swung back and locked upon the clutch principle. The projectile, or torpedo, is 25 ft. 6 in. long, 16 in. diameter, and, including the charge of two hundred and fifty pounds of dynamite or explosive matter, weighs fifteen hundred pounds. The body of the projectile is made of wood, and its shape can be best described by likening it unto an enormous cigar. The point, or dynamite section, is made of copper, and a cast-iron armature is affixed to the tail to balance the weight of the opposite end. The charge of powder is put into the space between the tail of the projectile—after it has been placed in the gun—and the breech of the gun, and then the breech closed. A fuse, connecting with the combustion chamber, is ignited by electricity. The initial velocity with which the torpedo leaves the gun is at the rate of one hundred and sixty miles an hour, or two hundred and fifty feet a second. With a minimum charge of powder in the gun the projectile traversed the first three hundred and ten feet in three seconds.

In all the experiments which have been conducted, common cord nettings have been used to determine whether there was really any trajectory in the travel of the torpedo. At firing distances of 250 and 300 ft. the course of the torpedo through the water was perfectly straight. The tide currents have no effect whatever on the course of the torpedo, nor can its course be detected as it travels through the water, as it does not make the slightest commotion when discharged. The torpedo is fired absolutely by concussion, and is calculated to strike a vessel at any point below the water-line. It has been proven that a vessel like the *Invincible*, even with a hundred water-tight compartments, could be sunk by a single torpedo, and that a mosquito fleet of torpedo boats could destroy the largest navy of ironclads. The *Destroyer* is intended to supersede steam rams; it attacks bows on in defiance of the opponent's fire, being protected by inclined transverse armour plates, and has an average speed of 16 miles an hour. Instead of having a lot of ironclads for harbour defence, forty or fifty *Destroyers* could be built and completely equipped for what one *Invincible* would cost.

The machinery of the vessel is entirely below the water-line, and below the intermediate deck, so that it is impossible for the boat to become disabled from the shots of the enemy. The main condenser of the engines, which is a pair of direct-acting, forms the bed-plate. The entire machinery is so compact that it only occupies a space less than 8 ft. square, and the engines may be worked up to 1,000 indicated horse-power. A single cylindrical tubular boiler, with two furnaces running fore and aft of the vessel, the fire-room connecting with the engine-room, furnishes the engines with steam; and the whole is so economically arranged that it only requires an engineer and fireman on each watch. A patent fan-blower keeps up the circulation of fresh air, and keeps a low temperature in the engine department. The steering gear, operated by hydraulic machinery, runs alongside of the keel, and the top of the rudder is 5 ft. below the water-line.

THE CORROSION OF IRON AND MILD STEEL.

AT the meeting of the Institution of Civil Engineers, held on Tuesday, the 22nd of March, Mr. Abernethy, F.R.S.E., President, in the chair, the paper read was on "The Comparative Endurance of Iron and Mild Steel when exposed to Corrosive Influences," by Mr. D. Phillips, M. Inst. C.E.

The author was a member of the committee appointed by the Admiralty, in June, 1874, to inquire into the causes of corrosion in boilers, and since the dissolution of the committee he had made further experiments with the same objects in view. The results were given of numerous tests, the surfaces of the specimens in nearly all cases being bright. Illustrations were shown of gutta-percha and plaster-of-Paris impressions taken from many of the specimens. Tubes of different brands of iron and steel were subjected to various tests in a special apparatus at Sheerness Dockyard. Some of the tubes were welded, others were cold drawn; with one exception, they were all specially prepared. Each tube had an exposed surface of 9.58 square feet. The iron tubes lost 45.4 per cent. less in weight than the steel. Small discs of iron and steel were also tested in another set of tubes in the same apparatus. The percentage in favour of the irons was 56.7. Pieces of iron and steel, of different brands, were suspended for twelve months in two marine boilers, one vessel having a jet condenser, and the other a surface condenser, and also in a feed-water heater supplied with fresh water. The percentages in favour of the irons were 32.7, 27.5, and 11.8 respectively. Plates of Bolton steel and Lowmoor iron, 10 in. by 8in., were likewise placed in the boilers of the two vessels mentioned. Half of the number were withdrawn after thirteen months, and gave a percentage in favour of the irons of 32.7—corrosion in the steels, in the form of pitting, being most marked. Of the remaining eight plates, four remained in the boilers twenty-one months and four twenty-two months, the result being 28.6 per cent. in favour of the irons. Plates of the same two metals, 15 in. by 8 in., were suspended for thirteen months in the feed-water heater. The percentage in favour of the irons was 10.9. The corrosion in the steels was only slightly more marked and irregular than in the irons. Plates of Lowmoor iron and Landore steel, suspended in pairs in vessels, under slightly different conditions, gave a percentage of 4.8 in favour of the irons.

The author next referred to a series of experiments with iron and steel plates (crucible, Bessemer, and Siemens steels, and Staffordshire and Yorkshire irons), suspended in the boilers of ocean and coast-going steam vessels belonging to various shipowners. The exposed surface of each plate was 37.87 square inches. Taking the results from fifty-six sets the percentage in favour of the two irons over the Bessemer and Siemens steels was 21.3. The different results obtained from some of the sets might be thus summarised: No. 43 set was suspended in the boiler 285 days. The boiler was filled fourteen times with fresh water, 2 in. of water being blown off daily. No. 2 set was in the boiler 311 days. The boiler was filled eight times with fresh water, and five times with sea water, 3 in. of water being blown off daily at sea, and 12 in. at intermediate ports. The mean loss of weight in No. 2 set was 825.4 grains, as compared with 347.7 grains in No. 43 set, or nearly 2½ times as much. Boiler 62 was filled five times with fresh water, 1 in. of water being blown off daily. The plates were in the boiler for 298 days. The mean loss of water was 364.9 grains, as compared with 825.4 grains in No. 2 set. Set 8½ was in the boiler 43 days, the boiler being filled four times with sea water and once with fresh water, an average of 73 in. of water being blown off daily. The mean loss of weight was 575.7 grains as against 364.9 grains in 62 set, being at the rate, per month of thirty days, of 401.78 grains in 84 set, against 36.7 grains in 62 set. Comparing set No. 9, which was suspended in a jet-condensing boiler, with 62, which was subjected to something like the most improved method of surface-condensing treatment, the loss in No. 9 was nearly four times that in No. 62 set. These results clearly proved the error of the conclusions arrived at by many experienced persons previous to the appointment of the boiler committee.

Experiments made by the author with plates similar to those last mentioned, placed in sea water, in rain water, exposed to the weather only, and exposed to the weather and dipped in sea or rain water daily, gave a result of 64·8 per cent. in favour of the irons, omitting the hard steel. The corrosion was strikingly local and severe in the set placed in rain water. Wetting the metals daily, especially with sea water, and exposing them to the weather, caused very severe corrosion. The results of these experiments incontestably proved, that under almost all circumstances iron, and especially the harder sorts, was far superior to steel in the resistance it offered to corrosion.

The author remarked that, in his opinion, such theories as that corrosion, was caused by galvanic action between metals and their oxides, or between different brands of iron or steel, or between iron and steel, were practically unworthy of consideration. He then proceeded to say that steel had probably received more than its fair share of praise as regarded homogeneity and uniformity of temper. Although iron was inferior to steel as regarded cinders, laminations, &c., yet mild steel was not without original defects, as was shown by several of the gutta-percha impressions. Moreover some of the tubes and discs before mentioned presented after testing a damaskeen appearance similar to gun barrels.

Surprising differences of temper were exhibited in the cold bending of the metals tested in the tube apparatus, not only between the various brands, but also between the tubes of each brand. The difference between the behaviour of the tempered and the annealed steel specimens under the cold bending test was also most marked.

It would seem that in the purifying of metals, in order to render them more ductile, elements, such as carbon, phosphorus, &c., were eliminated, which no doubt rendered the metals more liable to corrosion. In the metals tested in sea-going boilers the ordinary BB Staffordshire iron proved 9.6 per cent. better than the best Yorkshire, as regarded loss of weight, and the harder steel 20.9 per cent. better than the two mild steels. In the tube experiments the ordinary iron tubes proved 122.2 per cent. better than those specially prepared. Again, the tubes called "improved metal" were 31.1 per cent. better than the tubes called "improved homogeneous metal," by far the most ductile and expensive of the two.

It appeared from recent analyses that the percentage of phosphorus ranged from 0.20 to 0.21 in the cruder irons, from 0.7 to 0.14 in the better sorts, and from 0.016 to 0.04 in the milder steels. The amount of carbon in iron ranged from 0.0545 to 0.074 per cent., whilst in mild steel it varied from 0.131 to 0.273 per cent. From 0.0649 to 0.1080 per cent. of manganese was found in iron, and from 0.238 to 0.3317 per cent. in steel. These results confirmed the authors' conclusions, that the commoner irons, containing the most phosphorus, resisted corrosion better than the superior sorts, and the harder steels, containing the most carbon, better than the softer and finer sorts.

In conclusion, the author remarked that much yet remained to be done to produce a metal at once strong and ductile, but at the same time better able than mild steel to withstand corrosion. On the other hand, the treatment of marine boilers might be so modified, especially with the aid of zinc properly applied, as to enable the purer metals to be used in their construction.

THE new firm of shipbuilders established at Scotswood has, it is stated, secured a contract to build a large vessel for French owners. Shipbuilding at Scotswood In the upper reaches of the Tyne, is something to note. Hitherto only small boats—until the dredging of the Tyne Commissioners deepened the river—could be navigated to that locality. Little or no change had been made for centuries —probably ever since the Romans sojourned on the Tyne in that part of the ancient river. Fifty or sixty years ago an effort was made to get a company, with adequate capital, to cut a canal across to the Mersey to join, for purposes of navigation, the east with the side of the land, but the project fell through. That was long before the North-Eastern Railway was formed to Carlisle from Newcastle.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of the* MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Gironde.—On February the 26th Messrs, C. S. Swan & Hunter, Wallsend, launched an iron screw steamer, built for the Cardiff Steamship Company, and intended to run between Cardiff and France. The vessel was named the *Gironde* by Mrs. Hooper, of Sunderland, and will proceed to the Wear to have her machinery fitted by Mr. George Clark.

Fedele Primavesi.—On February 28th there was launched from the Jarrow-yard of the Palmers S. & Iron Company (Limited), a screw steamer bearing the above name, and of about 2,300 tons carrying capacity. This steamer has been built under special survey and to the highest requirements of Lloyd's 100 A 1 class. She will be fitted with every modern appliance for rapid discharge and reloading, as also for economy in every detail of working. She carries Emerson Walker & Co.'s Patent Brass Cone Brake Combination Windlass. She will be employed in the general carrying trade. This steamer is the third built by the Palmers Company to the order of Messrs. J. and R. Bovey, of London and Cardiff, and the christening ceremony was performed by Mrs. Robert Bovey, the wife of one of the Managing Owners. A special feature in the steamers managed by the above firm is that each steamer is registered under the Companies' Acts as the property of a limited company, thus securing to the shareholders immunity from liability beyond the amount of each share. This third steamer will be registered as the property of the Fedele Steamship Company (Limited). Messrs. J. and R. Bovey have also contracted with the same builders for a fourth steamer, of 2,700 tons deadweight capacity, and suitable for Atlantic, Mediterranean, or Indian trades.

Bothwell Castle.—On March 1st, Messrs. Raylton, Dixon & Co. launched from the Cleveland Dockyard, Middlesborough, a steamer built to the order of Messrs. Thomas Skinner & Co., of London and Glasgow, and will form one of their well-known "Castle" Line to China, for which Messrs. Dixon are also laying down for them another rather larger vessel. The *Bothwell Castle*, as the present vessel has been named, has a beautiful clipper bow, and full figurehead of Mary, Queen of Scots. She will carry nearly 4,000 tons of tea, and her dimensions are 345 ft. extreme length, 38 ft. 6 in. beam, 27 ft. 6 in. depth moulded, and about 2,600 tons gross register. Her decks, rails, and fittings are entirely of East India teak, and her passengers will be accommodated in a deckhouse aft wheel. She is fitted with Harfield's patent steam windlass and Bow & M'Lachlan's steam steering gear. The engines, of 280 horse-power nominal, are being constructed by Messrs. Thos. Richardson & Sons, of Hartlepool, where she will be taken next week to have them fitted on board.

Roseville.—On March 1st Messrs. W. Gray & Co. launched from their shipyard at West Hartlepool an iron-screw steamer, built to the order of R. Shadforth & Co., of Sunderland, which is the third steamer built by Messrs. Gray for them. Her dimensions are:—Length, 257 ft. 6 in.; breadth, 35 ft. 6 in.; depth of holds, 19 ft. and 23 ft. 6 in.; classed 100 A1 at Lloyd's, and built under the survey of Captain Thomas Watson, Hartlepool. The engines are 150-horse power by Messrs. Blair & Co., Stockton, and carries Emerson, Walker & Co.'s Patent Combination Windlass. She is built with double bottom on the new longitudinal and bracket system, and is specially fitted to carry grain under the new Act by having a permanent iron bulkhead full depth of hold all fore and aft. As she left the ways she was christened the *Roseville* by Miss Shadforth, of Fernville-house, Sunderland.

Mariner.—On March the 1st Messrs. M. Pearce & Co. launched from their iron shipbuilding-yard at Stockton-on-Tees, an iron screw steamer of the following dimensions, viz.:—Length over all, 257 ft., breadth extreme, 32 ft.; depth of hold from top of floors, 21 ft. 2 in.; gross register tonnage, about 1,420 tons. The steamer has been built to the highest class (100 A) at Lloyd's, under special survey. Has full poop, bridge, topgallant forecastle, and is fitted with three steam winches, patent windlass, &c. Engines are of 120-horse power, by Messrs. Blair & Co. As the vessel took the water she received the name of *Mariner*, and has been built to the order of a Liverpool firm.

Lockyer.—On March the 2nd Messrs. Bertram, Haswell & Co. launched from their iron shipbuilding-yard, South Dock, Sunderland, an iron screw steamer for Messrs. Wilkie and Turnbull, of North Shields. The principal dimensions are:—Length over all, 300 ft.; breadth, 37 ft.; depth, 24 ft. 6 in.; deadweight capacity, 3,100 tons. The vessel has been built under special survey to pass the highest class 100 A1 in London Lloyd's, and 20 years in Liverpool registry. She is specially designed for the American and Indian trades; the main deck is of iron, and the upper deck of iron covered with wood. She is built on the cellular tank system; has iron longitudinal bulkheads from keelson to main deck, in accordance with the provisions of the Board of Trade, in order to reduce the danger of cargo shifting (such as grain, &c.) to a minimum; has water ballast fore and aft, and is of immense strength. She is fitted with steam steering gear, and four large steam winches by Clarke, Chapman & Gurney, with Clarke's patent donkey boiler, also Emmerson, Walker & Co.'s Patent Windlass. She will be fitted with a pair of Mr. John Dickinson's compound surface condensing engines of 200-horse power, and provided with all the latest improvements in marine engineering. The vessel has a short full poop, topgallant forecastle for the accommodation of seamen and firemen, long bridge amidships extending over engine and boiler room. The ceremony of christening was performed by Mrs. Chas. Turnbull, wife of one of the managing owners, who named the vessel the *Lockyer*.

Plessy.—On March 2nd a steamer, named the *Plessy*, was launched from the ship building-yard of Messrs. Hodgson & Soulsby Cowpen Quay, Blyth. The *Plessy*, which is intended for the Indian and Atlantic trades, has been built to the order of Messrs. Watts, Ward & Co., of London, Newcastle, and Blyth, and is of the following dimensions:—Length over all, 264 ft.; extreme breadth, 36 ft.; depth of hold, 23 ft. She is built on the three-deck principle, and classed 100 A 1 at Lloyd's. The estimated dead-weight capacity of the vessel is about 2,450 tons, and she will carry about 10,000 quarters of heavy grain, besides 200 tons of fuel. The steamer will be fitted with compound surface-condensing engines of 160-horse power, with extra-sized boilers and shafting, the machinery to be made by Messrs Blair & Co., Stockton, and will be classed at Lloyd's M.C.

Embleton.—On March 2nd Messrs. W. Gray & Co. launched, from their yard at West Hartlepool, an iron screw-steamer, built to the order of Messrs. G. T. Pearson & Co., West Hartlepool, and is the second built for the same firm within three months. Her dimensions are:—Length, 256 ft. 6 in.; breadth, 34 ft. 6 in.; and depth of holds, 19 ft. 8 in., and 24 ft.; class 100 A 1 at Lloyd's, and built under the survey of Mr. Cornforth, of Hartlepool; engines, 150-horse power, by Blair & Co, Stockton; will carry a dead-weight of 2,350 tons. As she left the ways the new vessel was christened the *Embleton* (after a village near Wynyard), by Miss Pearson, of Castle Eden, daughter of the Managing Owner.

Saxon Prince.—On March 3rd an iron steam vessel, the *Saxon Prince*, was launched from the shipyard of Messrs. Swan & Hunter, at Wallsend. The ceremony of christening was performed by Mrs. N. B. Main, of Gateshead. The *Saxon Prince*, which is built to the order of Mr. James Knott, of Newcastle, is intended principally for the Bilbao trade, and is of the following dimensions, &c.:—Length, 215 ft.; breadth, 30·8 ft.; depth (moulded), 16·10 ft.; dead-weight capacity, 1,250 tons, on about 14 ft. 6 in. water; long raised quarter-deck, topgallant forecastle, with accommodation for crew, double bottom throughout for ballast, iron decks; engines, 100-horse power, supplied by Messrs. Black, Hawthorne & Co., and will be ready in April.

Fairfield.—On March 5th there was launched, from the Jarrow shipbuilding yard of the Palmers Shipbuilding & Iron Company (Limited), the screw steamer, *Fairfield*, built for Captain Joseph Brown and Partners, Liverpool. The *Fairfield* measures 260 ft. in length over all; 34 ft. beam, and 20½ ft. depth of hold, and is constructed to carry 2,200 tons deadweight; she is classed 100 A 1 at Lloyd's, and will be fitted with a pair of Palmer's compound surface condensing engines, of 30 in. and 60 in. cylinders, and 36 in. stroke.

Agnes Otto.—On March 15th a screw steamer, of the following dimensions, was launched from the iron shipbuilding yard of Messrs. John Readhead & Co., South Shields, namely:—Length, 260 ft.; breadth, 32 ft.; depth of hold, 18 ft.; and deadweight capacity, 1,900 tons. The vessel will be fitted by Messrs. Readhead & Co. with compound surface condensing engines of 130 nominal-horse power. She has been built to the order of Mr. George Otto, of North Shields, and upon leaving the ways she was named the *Agnes Otto*, by Miss Jenny Otto, daughter of the Owner. The new steamer will be employed in general trades, and will be commanded by Captain John Oliver, of South Shields.

Thorn Holme.—On March 17th Messrs. J. L. Thompson & Sons launched from their shipbuilding yard, North Sands, an iron screw steamer of the following dimensions, viz.:—Length, 260ft.; breadth, 36 ft,; depth of hold, 18 ft, 6 in.; and of 2,200 tons burthen, built under special survey to class 100 A 1 at Lloyd's, The engines, which are on the compound surface condensing principle, of 160-horse power, are being supplied by Mr. George Clark, of Southwick Engine Works. This vessel has been built to the order of Messrs. Hine Brothers, of Maryport. She will be fitted with four horizontal steam winches, Harfield's patent windlass, and patent steam steering gear by Donkin & Nichol, of Newcastle, and other modern improvements, The naming of the vessel, *Thorn Holme* was performed by Madame Lachere, of Antwerp.

Southbourne.—On March 18th the *Southbourne* (s) was launched from Messrs. Blumer's yard, North Dock, Sunderland. The vessel is the property and built to the order of Mr. D. P. Garbutt, of Hull. Her dimensions are:—Length between perpendiculars, 275 ft.; extreme breadth, 36 ft.; depth of hold, 24 ft.; gross tonnage, about 2,100 tons register; deadweight capacity, 2,800 tons. The *Southbourne* will be fitted with engines by the North-Eastern Marine Engineering Company, of 180-horse power. All the latest improvements have been introduced into the vessel to render her suitable for the Atlantic and Indian trades.

Abeona.—On March 19th a screw steamer, named the *Abeona*, built for Messrs. Graham, Anderson & Co., of Carlisle, Tyne Docks and Maryport, was launched from the iron shipbuilding-yard of Messrs. Bartram, Haswell & Co., South Dock, Sunderland. Her principal dimensions are:—Length between perpendiculars, 200 ft.; breadth, 30 ft.; and depth of hold, 15 ft. 6 in. She has been built under the inspection of the Liverpool Underwriters' Surveyors, also the Owners' Surveyor, and will obtain the highest class in the Underwriters' Registry. The general arrangements of the vessel are:—Topgallant forecastle, large bridge which covers and protects the engine and boiler rooms, and also covers the Officers' and Engineers' cabins; steam windlass of Emerson & Walker's patent; three powerful steam winches, by Clarke, Chapman, & Gurney; strong steering gear, and every convenience, including large hatchway, for the speedy and efficient working of the vessel. The cabins are aft under a half-poop. The engines have been constructed by Mr. John Dickinson, of Sunderland, and are of 120-horse power nominal, with cylinders 27 in. and 51 in. in diameter, with a stroke to each of 36 in.; boilers capable of bearing an ordinary working pressure of 80 lbs. per square inch. The ceremony of christening was performed by Mrs. Graham, wife of one of the Managing Owners, who named the steamer, *Abeona*. She will be under the command of Captain Temple.

Copley.—On March 19th Messrs. Ismay, Imrie & Co., of the White Star Line, received a further addition to their fleet of sailing vessels, making the second this year launched on the Mersey. The new vessel, which is named the *Copley*, is a ship of the following dimensions:—Length, 263 ft.; breadth, 39 ft. 1 in.; depth, 24 ft. 1 in.; and registering 1,750 tons nett, which has been built to their order by Messrs. W. H. Potter & Son, and was launched from the building yard of that firm at the Queen's Dock. The ceremony of naming the vessel was performed by Miss Anita Guthrie Williamson, daughter of Stephen Williamson, Esq., M.P. for the St. Andrew's Burghs, from whose estate in Cheshire the *Copley* takes her name.

Refulgent.—On March 21st Messrs. Short Brothers launched from their yard at Pallion, Sunderland, a screw steamer for local owners, making the ninth vessel built by them for the same firm. She is of the following dimensions:—Length, 216 ft.; breadth, 30 ft.; and depth of hold, 16 ft. 4 in.; with a deadweight carrying capacity of 1,400 tons. She is constructed on the cellular bottom principle, has a long raised quarter-deck, bridge-house over engines, and boiler amidships, and topgallant forecastle. She is constructed to the highest class in the Liverpool Registry, under special survey. The hatchways, four in number, are very large, for the purpose of self-trimming, and she has all the latest improvements for quick loading and discharging. On leaving the ways the vessel was named the *Refulgent*, the ceremony of christening being performed by Miss Mail, of Sunderland. After the launch the vessel was taken in tow for the South Dock, where she will be fitted with engines and boilers of 100-horse power by Mr. John Dickinson, Monkwearmouth.

Iron Acton.—On March 22nd there was launched, from the dockyard of Messrs. Raylton, Dixon & Co., of Middlesbrough, a steamer named the *Iron Acton*, built to the order of Bristol Owners for the timber trade. Her dimensions are:—Length over all, 235 ft.; breadth, 32 ft. 6 in.; depth of hold, 16 ft.; and she will carry about 1,450 tons on light draught. She has water ballast in after and main holds, and iron decks right fore and aft and will be fitted with engines of 100-horse power, by Messrs. Thomas Richardson & Sons, of Hartlepool.

Dawn.—On March 27th there was launched from the yard of Messrs. Edwards & Symes, at Cubitt Town, a screw steamer of the following dimensions:—Length, 100 ft.; breadth, 15 ft.; depth, 9 ft. This vessel is intended for the inter-island trade in the West Indies, and is the pioneer vessel of a company of colonial merchants, who have entrusted their commands to the firm of Messrs. Pile & Co.. As the vessel left the ways she was christened the *Dawn* by Mrs. C. H. Pile.

St. Donato.—A screw steamer named the *St. Donato*, of 2,200 tons, was launched a few days ago from the building yard of Messrs. Schlenger, Davis & Co., at Wallsend. She has been built to the order of the St. Donato Steamship Company, of Cardiff, the Managing Owners being Messrs. Harrison Brothers & Moore, also of Cardiff. The length of the *Donato* is 260 ft., breadth 35 ft., and depth of hold, 20 ft. 4½ in.

Brunswick (s.s.).—On March 2nd, Messrs. Wm. Pickersgill, of Sunderland, launched from their yard the s.s. *Brunswick*, built to the order of Mr. John Bacon, of Liverpool. She is a sister ship, so far as the model is concerned, to the s.s. *Stuart*, recently built by the same people for Mr. Bacon, but the general arrangement plan, which is the design of Mr. Joseph R. Oldham, under whose superintendence the ships and machinery have been constructed, is quite new. The vessel is 245 ft. by 33 ft. by 18 ft., and she will carry 1,910 tons dead weight. The saloon is amidships, with captain's room, spare state room, steward's berths, bath room, pantry, &c., all at fore-end of bridge, and the engineers' rooms and mess room are at the after end of bridge. There is an extra large wheel-house aft, and the chart room, companion and midship wheel-house are all in one. Two of the hatches are extra large, being suitable for taking in locomotives or large pieces of machinery. There is water ballast in both holds and in after peak. She is fitted with a very powerful steam crane and three large steam winches, Harfield's patent windlass, &c. The engines are by Mr. George Clark, of Sunderland, and are 130 nominal horse-power. The vessel takes the highest class in Lloyd's, and is considerably in excess of their requirements.

Embleton.—On March 17th a finely-modelled iron sailing barque—built to the order of Messrs. Peter Iredale & Son, Liverpool—was successfully launched from the shipbuilding yard of Messrs. Robert Thompson & Sons, Southwick, Sunderland, of the following dimensions, viz.:—226 ft. long by 36 ft. broad, and 21½ ft. depth of hold; having been built under Lloyd's special survey to class 100 A1. She has a raised quarter-deck and monkey forecastle, large iron deck-house amidships, with accommodation for crew and apprentices; cabin aft, fitted up for captain and officers, and with spare berths; and is fitted throughout with all the latest improvements for a vessel intended for the Indian and China trade. As she left the ways she was gracefully christened the *Embleton* by Mrs. Paynter, wife of the captain of the vessel.

LAUNCHES.—SCOTCH.

Carron Park.—On February 21st a screw steamer, named the *Carron Park*, was launched from the yard of the Campbeltown Shipbuilding Company. The *Carron Park* is a vessel of 550 tons register, 155 ft. keel, 12 ft. hold, and 23 ft. beam. She is built to the order of the Carron Steamship Company (Limited), Glasgow, being the maiden vessel of the firm, and she will be commanded by Captain R. Barclay. She is intended for the fruit and general cargo trade between Liverpool, Nantes, and the Rhone. She will be engined by Kincaid, Donald, & Co., Greenock. Miss M'Nair, Braefoot, named the vessel as she left the ways.

Quetta.—On March 1st Messrs. Wm. Denny & Brothers launched from their shipyard at Dumbarton an iron screw steamship of the following builders' dimensions:—380 ft. by 40 ft. by 30 ft. 6 in., and of about 3,400 tons, for the London and Calcutta line of the British India Navigation Company. She has been fitted with a pair of compound surface condensing direct-acting inverted cylinder engines of 500-horse power nominal, by Messrs. Denny & Co., Dumbarton. She is fitted for a large number of first and second-class passengers. As the steamer left the ways she was named the *Quetta* by Mrs. Macmichael, wife of Neil Macmichael, Esq., of Locksley, Helensburgh, and partner in the firm of Messrs. Wm. Mackinnon & Co., of Glasgow, and Messrs. Mackinnon, M'Kenzie, & Co., of Calcutta, agents in Calcutta for the British India Steam Navigation Company.

Algoa Bay.—On March 2nd Messrs. Russell & Co., shipbuilders. Greenock, launched from their shipbuilding-yard an iron barque of about 1,150 tons, which has been built to the order of Messrs. Hatfield & Co., Glasgow. The vessel's dimensions are as follows:—Length, 220 ft.; breadth, 35 ft; and depth, 21 ft. As she left the ways the barque was named the *Algoa Bay*.

Notting Hill.—On March 3rd there was launched at Messrs. Dobie & Co.'s yard, Govan, the first of three steamers which form an entirely new departure in our commercial Navy. The owners and designers of the *Notting Hill*, and her sister steamers, the *Tower Hill* and the *Ludgate Hill*, now in course of construction by the same builders, have adopted the twin-screw system now invariably applied to the armed Navies of the world, as they believe the modern Transatlantic steamer has reached the dimensions which require the application of means that have, after long trial, been found to ensure speed, handiness, and safety. The two screws at the stern of the *Notting Hill* will propel her 12 knots when laden, and will enable her to turn round almost in her own length, and allow her to entirely dispense with her rudder if anything should disable it. Should an accident befall one set of engines, or shafting, or propellers, the remaining set will propel the vessel at a speed of 10 knots, the average of ocean-going steamers. The *Notting Hill* is built entirely of steel, and it is claimed for her that she will deliver a larger cargoe on her draught than any steamer now running or building. Her 'tween decks, ready fitted with side lights, would carry upwards of 1,000 steerage passengers, or a whole regiment of soldiers, upon the one deck. She has been specially surveyed by the Admiralty, and her eminent fitness will enable her to take a prominent place in the transport service. She is provided, under Admiralty direction, with coal armour for the protection of her engines and boilers, and with such a number of bulkheads, all extending to the upper deck, that the steamer, when loaded, will float even if any one compartment is absolutely open to the sea. Her crank shafts are the latest improved built description, and of Vickers' steel. Her propellers are of the same material, and with movable blades. She is fitted with instantaneous hydraulic starting gear, that enables the movements of both propellers to be controlled at the same time by a mere child. She has Harrison's steam steering gear. Her boilers, 10 in number, with 20 furnaces, are of steel, made upon Turner's patent principle. She has four masts, and turtle backs forward and aft. In the latter ample space for the firemen and crew is provided, while in the saloon and state rooms, all on deck, accommodation has been furnished for cabin passengers in the best part of the steamer, well forward of the engines and boilers. She can carry upwards of 900 head of cattle, for which ample ventilation and movable fittings of the strongest and most improved designs have been provided, She has been constructed under special survey for the highest class at Lloyd's, both hull and machinery. Messrs. James Howden & Co. supplied the engines and boilers. As the *Notting Hill* left the ways the naming ceremony was performed by Mrs. W. H. Nott, of Sefton Park, Liverpool, the wife of the principal owner.

Ranee.—On March 3rd there was launched from Messrs. Ramage & Ferguson's shipbuilding yard, Leith, an iron screw steamer of about 700 tons, for the Borneo Company (Limited), of Singapore and London. The vessel's design is on the new shade-deck principle, and besides having a cargo capacity for about 10,500 piculs of rice, there will be considerable accommodation for both European and native passengers in the poop and deck-houses under the shade deck. Steam winches, steam windlass, and steam cooking apparatus, and many other appliances to suit the vessel for her special trade, which will be between Singapore, Sarawak, and Bangkok, have been introduced, and the arrangements for comfort in a hot climate have been carefully attended to. The dimensions of the hull are 185 by 27 by 21, and the engines, which are of the latest and most improved description, will be of 105 horse-power nominal. As the vessel left the ways, she was named the *Ranee* by Miss Russell, of Dunfermline.

Albingia.—On March 7th Messrs. Dobie & Co. launched from the Govan shipbuilding yard an iron screw steamer, built by them to the order of the Hamburg American Company, to the highest class, and measuring 1,900 tons. As she left the ways, she was named the *Albingia* by Miss Adelaide Isbister M'Ewan, of Barns Terrace, Ayr.

Bretton Hall.—On March 19th Messrs. Charles Connell & Co. launched from their shipbuilding yard at Scotstoun, an iron screw steamer of 2,500 tons. She is classed 100 A 1 at Lloyd's, and has been built to the order of Messrs. Alexander & Radcliffe, Liverpool, for their Hall Line, and is fitted up with every facility for the rapid loading and discharging of cargo. As she left the ways she was named *Bretton Hall*, and was immediately towed to the harbour to get her machinery fitted on board, which is being supplied by Messrs. John & James Thomson, Finnieston Engine Works.

Goval.—On March 19th there was launched from the building-yard of Messrs. Hall, Russell & Co., Aberdeen, an iron screw steamer named the *Goval*, of the following dimensions, viz.;—Length, 165 ft. by 23 ft. 6 in. by 12 ft. 6 in., and 450 tons gross register. This vessel has been built under special survey to class 100 A at Lloyd's, and will be fitted with compound surface-condensing engines 65-horse power nominal steam winches, water ballast, and all the most approved appliances for facilitating the loading and discharging of cargoes. The *Goval* has been built to the order of Messrs. Wm. Leslie & Co., and is specially fitted for the Continental herring and grain trade. Shifting boards and portable decks have been provided and arranged to prevent the crushing and shifting of cargoes. Mrs. John Leslie, of Donbank, performed the ceremony of naming the vessel, which was afterwards taken to the sheer poles for the purpose of receiving masts and machinery.

Lorna Doone.—On March 17th Messrs. Blackwood & Gordon launched a gunboat named *Lorna Doone* for Rajah Brooke, of Sarawak. The dimensions are:—Length, 100 ft.; breadth, 17 ft.; depth of hold, 8 ft.; and 150 tons. The builders have fitted the *Lorna Doone* with engines of 40-horse power. She is intended as an auxiliary gun and despatch boat. There are two 9-pounders on board.

Heron.—On March 19th Messrs. Scott & Co. launched from their building-yard at Bowling an iron screw steamer of 150 tons, built to the order of Messrs. R. Walker & Co., Clyde-terrace, Glasgow, and intended for the Loch Fyne herring trade. She will be fitted with compound surface-condensing engines of 45-horse power, by Messrs. R. Harvey & Co., Glasgow. As the vessel moved into the water she was named the *Heron* by Mrs. Gibb, Glasgow.

Palma.—On March the 22nd Messrs. H. M'Intyre & Co. launched from their shipbuilding-yard at Merksworth the *Palma*, an iron screw steamer of 1,100 tons, The *Palma*, which is the property of the Company La Islena, is intended for mail and passenger service between Palma, Barcelona, and Marseilles. She is built to the highest class at Lloyd's, and her passenger accommodation and cargo appliances are of the best description. The poop is fitted with saloon and sleeping accommodation for forty first-class passengers, and also two ladies' cabins, besides pantry, &c. There is accommodation forward for from 80 to 100 second-class passengers, besides two ladies second class cabins, the Officers and Engineers' rooms being placed amidships on main deck. The engines, which are compound surface-condensing and of great power, are being supplied by Messrs. Hutton & Corbett, Glasgow, and are expected to drive the vessel at a very high rate of speed. The ceremony of naming the vessel was performed by Miss Bews.

Bann Whatt Soon.—On March 22nd Messrs. Blackwood & Gordon, Port Glasgow, launched the *Bann Whatt Soon*, an iron screw steamer of about 500 tons, built for trading in the East. She will be fitted with compound engines of 80-horse power nominal by the builders.

Servia.—The Cunard Royal Mail steamship *Servia*, was launched on March 1st, from the shipbuilding yard of Messrs. James & George Thomson, Clydebank, near Glasgow, in presence of a large number of spectators. Great interest was taken in the event from the circumstance that the new vessel is fully 3,000 tons larger than such huge ships as the *Gallia*, the *Arizona*, the *Orient*, the *Furnessia*, and the *Parisian*, being in point of dimensions and tonnage exceeded only by Mr. Scott Russell's famous ship, the *Great Eastern*. The ceremony of naming the ship was gracefully performed by Mrs. John Burns. Among the company present were Mr. John Burns, chairman of the Cunard Company, the Earl of Ravensworth, Lord Balfour of Burleigh, Mr. Baring, Mr. Jardine, Mr. Cleland Burns, Mr. Cunard, Mr. Wilfrid Bevan, Mr. Williamson, Mr. Dudley Ryder, Mr. George A. Burns, the Lord Lieutenant of Dumbartonshire, Captain Townsend, R.N., and officers of Her Majesty's ship *Hercules*, Mr. and Lady Isabella Gordon, and Colonel and Lady Georgina Drummond Murray. The dimensions of the *Servia* are:—Length, 530 ft., breadth 52 ft., depth 44 ft. 9 in.; gross tonnage 8,500 tons. A better idea of the huge size of the vessel will be gained from the following facts. Her cargo capacity will be equal to 6,500 tons, with 1,800 tons of coal and 1,000 tons of water ballast, the vessel having a double bottom on the longitudinal bracket system. The anchor davits are 8 in., and the chain cable pipe 22 in. in diameter. The propeller shaft weighs 26¼ tons, and the propeller, boss, and blades, which are made of Vickers steel, are 38 tons in weight. The machinery consists of three cylinder, compound surface-condensing engines, one cylinder being 72 in. and two 100 in. in diameter, with a stroke piston of 6 ft. 6 in. It is anticipated that the indicated horse-power will amount to 10,500. There are in all seven boilers, six of which are double and one single-ended, and all are made of steel, with corrugated furnaces, the total number of furnaces being 39. Practically the *Servia* is a five-decker, as she is built with four decks and a promenade. The promenade, which is reserved for the passengers, is very large and spacious. On the fore part of it are the steam steering gear and house, captain's room, and flying bridge. On the upper deck forward is the forecastle, with accommodation for the crew, and lavatories and bath rooms for steerage passengers, while aft are the light towers for signalling the Admiralty lights, with the look-out bridge on the top. Near to the midship house are the captain's and officers' sleeping cabins. Next to the engine skylight is the smoking-room, which can be entered from the deck or from the cabins below. It is unusually large for a smoking-room, being 30 ft. long by 22 ft. wide. Near the after-deck house is the ladies' drawing-room, to which access can be obtained either from the music-room or from the deck. Abaft of this, and in the upper end of the upper deck, is the music-room, which is 50 ft. by 22 ft. in dimensions, and which is to be fitted up in a handsome manner with polished wood panellings. Immediately abaft of the music-room is the grand staircase, which leads to the main saloon and the cabins below on the main and lower decks. For the convenience of the passengers there are no fewer than four different entrances from the upper deck of the ship to the cabins. At the foot of the stair leading to the saloon and also in the cabins the panellings are of polished Hungarian ash and maple wood. The saloon is very large, being 74 ft. long by 49 ft. wide, with sitting accommodation for 350 persons, while the clear height under the beams is 8 ft. 6 in. The sides are all in fancy woods, with beautifully polished inlaid panels. All the upholstery of the saloon is of morocco leather. Right forward of the after deck are the pantries, baths, lavatories, and state rooms. The total number of state rooms is 168, and the vessel has accommodation for 450 first class and 600 steerage passengers, besides a crew of 200 officers and men. For two-thirds of its entire length the lower deck is fitted up with first class state rooms. The ship is divided into nine water-tight bulkheads, and she is built according to the Admiralty requirements for war purposes. A special feature is the arrangement of the water-tight doors in the engine and boiler spaces. According to the usual method, the door requires to be screwed down, and this process takes up a considerable time. In the *Servia* they can be shut from the upper deck in case of accident in a couple of seconds by simply using a connecting-rod. There are in all 12 boats, and these are equipped as lifeboats, and have Hill & Clark's patent improved boat-lowering apparatus. The keel of the ship consists of five thicknesses, making a total thickness of 6¾ in.; and in order to secure thoroughly reliable workmanship, the riveting was done by Tweddell's hydraulic riveter. All the frames and beams of the ship were riveted by this process. The upper deck is of steel, covered with yellow pine; the main deck is of steel, with a teak covering; and the lower deck is of steel, with a covering of teak above the engine and boiler spaces. All the deck-houses and deck fittings, which are liable to be carried away in a heavy sea, are made of iron and steel, and are riveted to the steel decks underneath. The *Servia* possesses a peculiarity which will add to her safety—namely, a double bottom or iron skin. Thus, were she to ground on rocks, she would remain perfectly safe while the inner skin continued intact. There are three masts on the vessel, and the Cunard Company have adhered to their special rig, believing it to be more ship-shape than the practice of fitting up masts according to the length of the ship. On these masts there will be a good spread of canvas to assist in propelling the vessel. At the luncheon which followed the launch, Mr. James R. Thomson proposed the toast of "Success to the *Servia*," coupling with it the name of Mr. John Burns, the chairman of the Cunard Company. Mr. John Burns expressed his thanks for the honour done to him in coupling his name with that of the great ship which had been launched, and, in acknowledging the toast, said the difference between their first Atlantic steamer, the *Britannia*, and the *Servia* was marvellous. The *Britannia* started on her first voyage more than 40 years ago. She measured 1,139 tons, had a capacity for 225 tons of cargo, and steamed 8¼ knots an hour. The *Servia* measured 8,500 tons, would carry upwards of 3,000 tons of cargo, with 2,000 tons of coal, as well as 1,000 passengers, and would maintain a speed, he hoped, of not less than 17½ knots an hour. These figures, he remarked, showed at a glance the vast changes which had taken place in steam navigation, and from what he saw in the development of new materials and scientific inventions, he believed that we were upon the threshold of still greater achievements. In the *Servia*, he said, a notable instance was shown of how, as iron superseded wood, steel is superseding iron, and he well remembered the careful calculations into which he went with Mr. James Thomson, the designer as well as the constructor of the *Servia*, in regard to the advantages of steel, and also the crucial testing by scientific experiment of the article itself before he recommended its adoption to his partners. In addition to being stronger and more ductile than iron, it was of less weight, as would be seen when he mentioned that the *Servia*, if built of iron, would have weighed 620 tons more than she did, and would have entailed the drawback of a corresponding increase in draught of water. In regard to scientific discoveries and inventions, he thought that science was, if anything, tending to tread too hastily upon the heels of commerce, there being no portion of a ship, from stem to stern, from truck to keel, which was not subject to suggestive improvement by scientific men; and he could assure them that it required all the proverbial blandness of a chairman to decline the overtures of hosts of suitors who came to ask him to adopt their varied wares. Still, without doubt, there were looming in the future some scientific discoveries which he believed would come to play a most important part in navigation; and he thought we might assume as more than probable that electricity would yet form a powerful factor in the economy of mechanical locomotion. In the meantime the duty of those who conducted great maritime enterprises was to keep their eyes open to everything which would conduce to safety and comfort, conducting their business upon the lines of a liberal and enlightened policy, the best means, he was convinced, of producing results alike satisfactory to the general public and to those who invested their money in maritime adventure.

TRIAL TRIPS.

Parisian.—The new Allan Liner *Parisian*, of a gross tonnage of 5,050 tons, made an experimental run from the Clyde on February 26th previous to her departure for Liverpool. She has been built by R. Napier & Sons for the Montreal Ocean Steamship Company's Royal Mail service between Liverpool and Montreal. She is 450 ft. long, 46 ft. broad, and 36 ft. deep, and will carry a load of 10,000 tons. She stood high in the water on February 26th, with about 2 ft. of her screw showing, so she was not tried for speed, but her three-cylinder compound engines are constructed to indicate 6,000 horse-power, and to propel the ship from 15 to 16 knots an hour. She has four double-ended boilers, with 24 furnaces. Her hull is constructed of steel, with an inner and outer skin, 5 ft. apart, divided into water-tight compartments, designed for safety, but available for water ballast. She has also 10 water-tight bulkheads. She carries a Trotman and a Martin anchor. The main saloon, accommodating 150 first-class passengers, is placed in the fore-part of the vessel, and so are the state rooms; the second-class state rooms are still further in front.

Nithsdale.—The screw steamer *Nithsdale*, built and engined by Messrs. Cunliffe & Dunlop, Port Glasgow, for Messrs. M'Kill & Co., Glasgow, went her trial trip on the Clyde on February 28th. The dimensions of the *Nithsdale* are:—Length, 240 ft.; breadth, 32 ft. 6 in.; and depth, 17 ft. She has a carrying capacity of 1,650 tons, and is fitted with engines of 130-horse power. She is to be employed in the Mediterranean trade, and has extensive poop accommodation. Special quarters are fitted up amidships for the Officers and Engineers. The vessel left Port Glasgow about noon, with the owners, builders, and a large party of friends on board. On the measured mile she obtained an average speed of 12 knots, equal to about 15 statute miles per hour—a speed which gave complete satisfaction. The modern improvements with which the vessel is fitted include Dunlop's patent governor, for preventing damage to the machinery through the rapid revolution of the screw when raised out of the water by heavy weather.

Penang.—On March 7th the *Penang* (s), built by Messrs. Ramage & Ferguson, Leith, for Chinese owners in Singapore, to the order of Messrs. John Warrack & Co., went out for her official trip with very satisfactory results. With 730 tons dead weight on board, on a mean draught of 13 ft. 1 in., a speed of 10¾ knots was easily attained, the consumption of coal being at the rate of 10 tons per day. On the run down to the Bass Rock a very heavy sea was encountered, and the vessel's sea-going qualities were thoroughly tested to the satisfaction of all concerned. The *Penang* will now shortly leave Leith for Singapore, the crew being all Lascars, sent here specially to sail her out, and on arrival there will at once be placed on the trade between the Straits Settlements, Borneo, Java, and Celebes.

Jane Kelsall.—The screw steamer *Jane Kelsall*, built by Messrs. Readhead & Co., South Shields, for Messrs. W. D. C. Balls and Partners, had her trial trip on March the 10th. She has been specially built for the Atlantic and Indian trades, and classed 100 A1 at Lloyd's under the three-decked rule, with two decks laid, main deck being of iron. Her dimensions are:—Length over all, 275 ft.; breadth, 35½ ft.; depth, 23 ft. Her deck plan is top-gallant forecastle, with iron deck sheathed with wood, and fitted with berths for crew. Bridge amidships over engines and boilers, with engineers' berths, &c. Poop aft with cabin, captain and officers' berths, and a few berths for passengers. She has engines of 170-horse power nominal, supplied by Messrs. John Readhead & Co., and is fitted with patent steering gear on bridge and poop aft. The trial was highly satisfactory, the speed of the vessel averaging 11 knots per hour. On her return to the harbour the vessel was taken direct into Tyne Dock, where she will load a cargo of coals for Genoa, thence to Benisaf and Baltimore. The *Jane Kelsall* will be commanded by Captain Grey, of South Shields.

Ethelbert.—On March 12th the *Ethelbert*, a screw steamer, 170 ft. by 24 ft. 6 in. by 13 ft., having compound engines of 70-horse power nominal, ran the Lights on the Clyde, and attained a speed of 10¾ knots. She is of the highest class at Lloyd's, and has been built to the order of Messrs. A. C. Colvil & Co., Glasgow, by Messrs. Workman, Clark & Co., of Belfast, and engined by Messrs. Muir & Houston, Glasgow. The working of the machinery gave great satisfaction, as also the vessel herself. The steamer is intended for the Glasgow and Mediterranean trade.

Maud Hartmann.—This screw steamer, built by Messrs. Schlesinger, Davies & Co., Wallsend, a few weeks ago, had recently a satisfactory trial trip. This vessel was built for Messrs. Ward and Holzapfel, of Newcastle, and her leading measurements are:—Length between perpendiculars, 260 ft.; breadth, moulded, 35 ft.; depth of hold, 20 ft. 4½ in.; register tonnage, 1,070 tons; and she has a carrying capacity of about 3,400 tons. She classes 20 years in red in the Liverpool Underwriters' Registry, and is in every way fitted out as a first-class ocean-going steamer. The vessel went to sea loaded with 2,382 tons of coals, and her engines were tried with great success, the indicated horse-power being over 700, and the mean speed attained over nine knots. The *Maud Hartmann*, after giving up her visitors to the attendant tug, steamed off for Bombay.

Correspondence.

[*It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions referred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.*—ED.]

To the Editor of the MARINE ENGINEER.

DEAR SIR,—I have been a reader of your valuable journal for some time now, and in comparing dimensions and results of trials in the very interesting columns devoted to "Launches and Trial Trips," I find myself "quite at sea" as to the meaning of various terms used therein.

Several of my fellow-workmen and I would feel ourselves under a great obligation if you would kindly explain the meaning of the following terms:—"gross tonnage," "gross tonnage register," "registered tonnage," "nett registered tonnage." Which of the above does "dead weight carrying capacity" come under? Explain the difference between "tons gross register" and "tons builders' measurement."—Yours very sincerely,

NOVICE.

London, *March 14th*, 1881.

GROSS TONNAGE, *or*, GROSS REGISTER TONNAGE, is the entire *internal* capacity of the vessel in cubic feet divided by 100.

In most vessels several deductions are made from the above;—for instance, the tonnage of the space occupied by the crew, or used for the navigation of the vessel, and in steam vessels a further deduction is made on account of the space occupied by the propelling machinery. The remainder, after all deductions allowed by law are taken away, is called the *register tonnage*, or, *nett register tonnage*, and is the tonnage upon which dues, &c., are paid.

The dead-weight carrying capacity does not come under either of the above heads,—it depends not only on the *external* capacity or displacement of the vessel, but also on the weight of the vessel itself, the weight of machinery, bunker, coals, &c., and weight of stores and equipment, all of which are independent of the *internal* capacity or tonnage of the vessel. For instance, a vessel built very strongly, and consequently heavily, and fitted with heavy and powerful machinery, will be able to carry much less dead-weight than a vessel of precisely the same outside form, but lighter built and fitted with less powerful machinery.

Builders' measurement tonnage is an exceedingly arbitrary and unscientific term:—it depends upon the length, breadth, and depth of the vessel only, and not upon the *form* of the vessel; so that a box-shaped vessel would be the same builders' measurement tonnage as a vessel finely shaped like a racing yacht, with the same length, breadth, and depth.—ED. M.E.

To the Editor of the MARINE ENGINEER.

DEAR Sir,—Will you or some of your kind readers furnish formulæ and results for the HP. of following conditions of a compound steam engine?

1st. Area of cylinder, 144 sq. in.; stroke, 2 ft.; revolution, 1; steam, (85·3 + 14·7) 100 lbs.; cut-off at ·5 (in this cylinder), and 2nd cylinder of double volume.

2nd. All conditions same as 1st, with exception of the 2nd cylinders, but of equal combined capacity of 2nd cylinder of 1st case.—Yours, &c., WOOLF.

Newton, *March 4th*, 1881.

Reviews.

The Practical Guide to the use of Marine Steam Machinery. By Jas. Donaldson. Published by Chas. Wilson, 157, Leadenhall-street.

We have perused this book with much pleasure, as it bears throughout the marks of a practical writer, who does not confuse his readers or himself by attempting high-flown scientific calculations or descriptions. The book abounds with excellent practical hints as to the management and care of marine engines. Many illustrations of launches and engines are given, all from the best and latest examples; and the letter-press is not only merely descriptive of the examples, but abounds in easy rules and calculations applicable to cognate cases. Many of the tables of dimensions, powers, strengths, &c., would be exceedingly useful to a marine engineer. The whole book is excellently and clearly printed, and very tastefully got up.

Wood-working Machinery. By Mr. Powis Bale. Published by Crosby, Lockwood & Co.

This volume is one of the most comprehensive collections of examples and descriptions of all classes of wood-working machinery. There is, of course, a great deal of it of no special interest to marine readers, but as wood still forms so large a part of the structure of many vessels and of their fittings, there are many machines herein described of interest to shipwrights. In especial, Chapter XXVII. deals in part with machines for sawing out ship's timbers to a correct bevel, and an invention of a Mr. Green to ensure accuracy in the bevel, without depending on the eye of the workman, is very interesting. A small diagram of the required bevel is wound round a roller, and a mechanical tracer is made to follow the line of the diagram, and thus ensure a corresponding bevel cut by the saw. Mr. Normand's machine for cutting ship's timbers is also described, and there are many other machines applicable to a shipwright's purpose. The plates and type are excellently clear and good.

How to Manage a Steam Engine. By Mr. Powis Bale. Published by Wyman & Sons, Great Queen-street.

This is a small and handy volume for the information of factory owners, colonists, or others who have to rely on their own probably unskilled services. Most of the different varieties of engines are treated of, and their peculiarities are described. Useful hints about boilers, feed-pumps and fittings are not forgotten, and the work closes with valuable information about gas engines, which are now coming so rapidly into use, and of which we should imagine there is as yet very little written information to be had.

Notes and Novelties.

MR. TH. RODENACKER, of Dantzic, in conjunction with Messrs. Bremer, Bennett, & Bremer, of London, have contracted with Messrs. C. S. Swan & Hunter, of Wallsend-on-Tyne, for a screw-steamer of similar dimensions to the *Annie*, recently built at the same yard for the above firms. The engines are to be constructed by Messrs. Black, Hawthorne & Co., of Gateshead.

THE IRON AND STEEL INSTITUTE.—The programme for the annual meeting of the Institute, on the 4th, 5th, and 6th of May, has just been issued. Mr. Josiah T. Smith's experience as one of the largest steel manufacturers in this country will give his Presidential address an exceptional interest. Mr. Alex. Wilson, of Sheffield, will read a paper on the manufacture of armour plates. The subject of the manufacture of steel and steel plates will be dealt with by Mr. Sergius Kern, of Russia, who will bring before English manufacturers and users of steel, improvements recently practised in Russia; while the experience lately gained in the practical use of steel for ship-building purposes will be dealt with in a paper by Mr. Denny, of Dumbarton. The question of the relative corrosion of iron and steel will be discussed by Mr. Wm. Parker, of Lloyd's. A paper is promised by Captain Jones, manager of the Thomson Steel Works, Pittsburg, on the manufacture of Bessemer steel and steel rails in America.

THE "DUILIO."—The following is an extract from a letter written by an officer, an impartial observer of things appertaining to the Italian Navy:—"I have seen the *Duilio* off Messina in rough weather. While on her voyage to Milazzo she shipped a very small quantity of spray, which was not the slightest hindrance to her artillery service, as she rolled almost imperceptibly, while the *Maria Pia* and the *Principe Amadeo*, on board of one of which vessels I was, scarcely could resist the seas, which caused them to roll and pitch strongly. If the *Duilio* had been an enemy she could have sunk us without firing a shot, unless we had preferred to save her the trouble by going down of ourselves. I do not know what will be the immediate result of the question as to large or small men-of-war, but I doubt not that the superior qualities of our so-called colossal vessels will finally be proved, and future history ought to be very severe with those who, actuated solely by personal motives, injure the development of our means of offence and defence. Meanwhile the *Duilio* has completed her artillery practice, during which the guns behaved admirably." An official trial is soon to be made of the heavy artillery of the *Duilio*. The experiments are to take place in the Gulf of Gaeta.

LIGHTHOUSE DISTINCTION.—At the Society of Arts lately Sir William Thompson read a paper on the subject of the best means of making a lighthouse fulfil its *raison d'être* of being distinguishable at once from a vessel's light at sea or a shore light, and not being confounded with any other lighthouse on the same coast. Sir William brings to his task not merely his highly-trained scientific intelligence, but no inconsiderable practical experience as a navigator, and his conclusion is that the most useful and satisfactory means is to adopt the system of "group-flashing," under which a lighthouse would give a series of groups of flashes, not exceeding four, at very brief entervals, with a sufficiently long period between the groups to divide them beyond the possibility of doubt. He proposes ten varieties, which are sufficient to define all the numerous fixed lights round our coast, made up of long eclipses of three seconds, and short eclipses of one second, with intervals between the beginning of one group and the beginning of the next of ten, twelve, fifteen, and twenty seconds. By means of a model apparatus for producing these occultations and a gas jet, he showed practically how perfectly distinctive signals produced in this way were, and instanced cases in which the principle has been most successfully applied in practise, both by the Trinity House and the Board of Scottish Lighthouses. He insisted on the importance of applying the same principal to the sounds of syrens, or fog horns of lighthouses, adopting Admiral Sir R. Collinsons's suggestions of high and low notes being brought in direct contrast.—In the discussion which followed, Professor Tyndall heartily endorsed the necessity for such means of distinctiveness, declaring that in certain conditions of the atmosphere, a candle in a lanthorn, and the electric light, were undistinguishable by mere appearance. He also announced that the Elder Brethren of the Trinity House were alive to the necessity of this distinctiveness, and were working in that direction.—Very general approval was given to Sir. W. Thompson's proposal, and he received a hearty vote of thanks.

REMOVING OBSTRUCTIONS IN NEW YORK HARBOUR.—The destruction of Hallett's Reef, which formed one of the obstructions of Hell Gate in New York harbour, will long be remembered as a successful piece of difficult engineering work. Since this was removed, General Newton has been engaged upon a similar, but more important undertaking forming part of the same enterprise. This is the removal of Flood Rock, the largest and most dangerous obstruction in Hell Gate, and which will involve a final blast with 200,000 lb. of powder, while the explosion at Hallett's Reef was made with 50,000 lb. of powder. The exterior works are established on the crown of the Flood Rock, which, being below the level of high water, is surrounded with a cofferdam. The works comprise a blacksmith's shop where drills, &c., are forged, a repair shop for the machines employed, boiler-house and pumps. A perpendicular shaft was first sunk through the rock to the level of the horizontal workings, the floor of which is 60 ft. below the high-water level, and about 34 ft. below the bed of the river. From a gallery connected with this shaft 10 tunnels, parallel to each other, and running in the direction of the river, are driven; these are at present 600 ft. long, and are connected by 13 smaller cross galleries. Along the main galleries tracks are laid, and the stone excavated is led on cars to the foot of the shaft, and thence is hoisted and deposited in barges. Some of the excavation was employed to protect the outer side of the dam enclosing the works, but the greater part is thrown into a deep hole in the river close by. Already 783,000 cubic ft. of stone have been removed, and as the work will progress for two or three years longer, some idea of its magnitude may be obtained. The excavation is effected by steam-worked rock drills and blasting. There are 10 drills, each capable of boring 25 holes a day, 4 ft. deep and 2 in. diameter. The blasting is done on the evening of each day, the average rate of progress being about 500 ft. of tunnel per month. It is expected that the preliminary work will be completed in 1883, and that the great blast of 200,000 lb. of powder will take place the same year. A similar system will be adopted to that so successfully used at Hallett's Reef; the workings will be filled with water before firing the charge.—*Engineering*.

EDITORIAL NOTES.

THE dangerous explosions of gas, to which coal-carrying vessels are so liable, have at last received the earnest attention of the Marine Department of the Board of Trade. There is no better precaution against such explosions, known at present, than thorough ventilation. With this view the Board draw especial attention to their recommendation that "free and continuous egress to the open air independently of the hatchways, should be provided for the explosive gases by means of a system of surface ventilation which would be effective in all circumstances of the weather." Not only, however, does he Board direct attention to this recommendation, but enforces it by warning certificated masters and officers that neglect on their part in the case of accident, would be brought before the notice of the Wreck Commissioner or of the Court investigating the case. The shipowners are also not overlooked, but are advised that it is the intention of the Board to prosecute those persons who in future send or take to sea British coal-laden ships which, on account of insufficient or improper ventilation, are in such an unseaworthy state that the life of any person is likely to be thereby endangered, and all persons who so neglect their duty in respect of ventilation as to cause danger to life or limb. This is pretty hot for both masters and owners, but after the conclusive evidence given before the Royal Commissioners appointed to enquire into the spontaneous combustion of coal in ships, it is scarcely to be wondered at.

MANGANESE BRONZE seems to be the metal of the future. It appears to have fully one hundred per cent. greater tenacity than gun-metal, and an equal increase of elasticity. For propellers this is an incalculable advantage. The elasticity of the blades of a propeller would be all important in preventing jar and vibration upon the shaft and engine. The thinner section that might be used would also offer less surface and resistance to the water, whilst equalling the strength of a gun-metal blade of much thicker proportions. A propeller of this metal is about to be fitted to the *Colossus* instead of in gun-metal as at first ordered. This decision has been arrived at after a series of conclusive experiments on comparative bars of gun-metal and Manganese bronze of the same section. Bars of one-inch square were placed on supports twelve inches apart, and first subjected to a steadily increasing pressure on the centre of the bars, and afterwards to the impact of a weight of fifty pounds falling through a height of five feet. The gun-metal bars either broke or slipped between the support by doubling up at a steady strain of 28 cwt., whilst the Manganese bronze bars required 54 cwt. to effect the same result. When tested by impact, seven to eight blows were sufficient to break down the gun-metal bars, whilst the Manganese bronze withstood thirteen to seventeen blows. The ultimate bend of the

Manganese bronze was also in both cases greater than that of the gun-metal, thus showing greater toughness as well as double the strength in the former than in the latter.

Sir John Hay seems to have but a poor opinion of the present state of the British Navy. He considers that England's safety requires a minimum of at least sixty-two ironclads, whilst at present we are not blessed with more than forty-one. France alone, it seems, have more ironclads than we, which seems in Sir John Hay's opinion, to seriously threaten England's assumed position of "Mistress of the Sea." He seems to forget that in olden times it was not an excess in numbers, but the superiority in pluck and efficiency that gave us the many naval victories of which we are now so proud. We do not think our supply of seamen is in half so satisfactory a condition as the supply of ironclads. We have only in our navy, 18,500 seamen and some 12,000 naval reserve. In the case of a war requiring the co-operation of our navy, it appears to us that it would be more difficult to successfully man a large increase of our cruising navy, than to find suitable fast steamers from the mercantile marine to reinforce our naval power. Such a large proportion of the seamen serving in our mercantile marine are foreigners or Lascars that we could in no wise rely upon that body for serviceable recruits. There is so little inducement held out to good seamen or engineers in the mass of our mercantile marine, that we cannot be surprised at the large proportion of foreigners and disreputable characters manning our cargo vessels.

The American Continent is a country of gigantic scenery and possibly of correspondingly gigantic enterprises. We see that they possess what we should suppose to be the largest ferry boat in the world. The vessel called the *Solano* plies at the mouth of the Sacramento river in Californa, and forms a connecting link in the Grand Central Pacific Railway, carrying over trains from Benicia to Port Costa on the direct route from Sacramento to San Francisco. The length of the deck is 129 metres, and the width of the platform nearly 35½ metres. The draught of water (when loaded) is about two metres, and the tonnage is 3,600. These dimensions are so considerable that the vessel can carry four lines of railway abreast which will accomodate forty-eight wagons with their locomotives, or twenty-four passenger cars of the American type. The *Solano* is a paddle vessel, with paddle wheels 9·14 metres in diameter, which are independent of each other, and each is driven by a vertical beam engine of 2,000 horse-power. These paddles are not placed outside the vessel, but are placed behind each other in the longitudinal axis of the vessel. The vessel is steered either way by four balanced rudders worked by hydraulic apparatus driven by independent steam engines.

We regret to see that a valued contemporary journal from which we, last month, published a considerable extract upon the Navy Estimates, as presented to the House by Mr. Trevelyan, does not seem to consider that there is much ground for the present feeling of the engineers of the Royal Navy, as to their inferior status compared with the combatant officers. It is not that this grievance is not generally known to exist, but this journal considers that the acknowledged inferior status of the engineers is due to their personal inferiority in education and social standing. We would beg emphatically to remark that it is this very want of social recognition that debars many of the best nurtured and educated naval engineers from remaining in the service when they can have a good opportunity to get out. Of this we know many forcible instances amongst personal acquaintances. The surest way of securing gentlemanly and well educated engineers for the service, is first to acknowledge them as such. On another point also we must greatly demur to the statement of the said contemporary that the naval engineers' position is more suited to the practical artizan than to the educated gentleman. As the success of any marine battle will now almost entirely depend on the condition and success of the engineering appliances on board, we cannot in any way agree to the opinion that the naval engineers' position is not one requiring brains and education. To our mind this is more a necessary qualification to the engineers than to the combatant officers, since the work of the former is more technical and scientific. In the case of sudden break down by weather or shot, the whole safety and power of the present iron-clad would depend upon the ingenuity and skill of the engineer officers for a temporary refit. Such impromptu work is essentially that of a designing, inventive, and educated mind of the highest order. To the suggestion also of our contemporary that one such educated engineer would be sufficient with surbordinate foremen, we think a sufficient answer to that lies in the perils of warfare, requiring several suitable subordinates ready at once to step into their leader's place in case of accident.

The failure of the steel plates of the boilers of the *Livadia* have given rise to a great deal of uncomfortable doubt as to the reliability of steel plates for boilers. This is a most important subject, as so many boilers are already built of steel plates, and the number is daily increasing. The confidence of boiler makers in steel plates is at present so great that we find them specified for the crowns of fire-boxes in place of the best Lowmoor. The faith of such boiler makers must have received a very rude shock, not only from such an unaccountable failure as that of the plates of the *Livadia's* boilers, but also from a circular just issued by the Admiralty. We call the failure of the *Livadia's* boiler plates unaccountable because the plates had answered every test for tensile resistance and ductility most admirably. It is almost impossible then, with our present knowledge, to form an idea how a perfectly ductile material can have developed a crack twelve inches long in a half-inch plate without having been subjected to any severe strain. The Admiralty circular to which we have referred may throw some light on the matter. It appears from Government tests embodied in this circular that steel loses its ductile and tenacious properties at a very low temperature, in fact little higher than that of ordinary high pressure steam. At such temperatures it is found that the steel plates cannot be bent without fracture. This is a startling statement, and if found to be generally true, the worst possible place to which steel plates could be fitted, would be over the fire in the fire-box crown. At any rate for the future no *cold* tests of steel boiler plates can be accepted as any evidence of its ductile or tenacious qualities when at the ordinary temperature of a boiler or of a crown plate. These facts will not militate in any way against the value of steel for shipbuilding purposes. It is only to boilers that the value of its application is to say the least, at present very doubtful.

THE INSTITUTION OF NAVAL ARCHITECTS.

THE annual meeting of the Institution of Naval Architects for 1881 was held on the 6th, 7th, and 8th of last month, in the Hall of the Society of Arts, John Street, Adelphi. The president, the Earl of Ravensworth, filled the chair. The proceedings commenced on the 6th with the transaction of the general business of the Institution, such as the election of the Council and of new members. The annual report of the Council was then read. The Council deeply regretted having to announce the death of Lord Hampton, the late President of the Institution. Lord Hampton, who only resigned at the close of the last annual meeting, had been president of the Institution ever since its foundation in the year 1860. His lordship's services are fresh in the memory of every member and associate, and the best testimony to them is the flourishing condition in which he left the Institution. The Council was glad to be able to report that the funds of the Institution continue to be in a satisfactory condition. Acting upon a generally expressed wish the Council has, during the past year, caused the preparation of a General Index of the twenty-one published volumes of Transactions. This index is now completed, and will be shortly on sale at the price of ten shillings to the general public, and only five shillings to members and associates of the Institution. At the invitation of the Lord Provost of Glasgow and of the committee of the Naval and Marine Engineering Exhibition, a deputation from the Council proceeded to Glasgow in November last, in order to represent the Institution at the opening of the Naval Exhibition. The deputation is of opinion that exhibitions similar to that now being held in Glasgow are, when systematically organised, of great interest and utility, and might with advantage be held at fixed intervals of time.

After some further business of a general character had been transacted, the president proceeded to address the meeting. He said that at this time last year he had hoped that upon this occasion he should be able to congratulate them upon a general and decided revival of trade. These hopes had not been realised. The excise and revenue estimates, which were the best indications of the general condition of the people and their consuming power, showed a deficit upon the year, and in the last quarter it was the most unfavourable of the whole year. The railway traffic returns also were very accurate indications of the general condition of business; and trade in the country showed a serious falling off the last quarter, which was by no means satisfactorily accounted for by a bare reference to the rigorous winter, out of which we seemed hardly yet to have emerged. But though the general condition of trade was bad, there had been progress noted in certain branches in our trade from time to time during the year; but the progress, where it had been observed, had been fitful and fluctuated, and truth forbade him to offer them cordial congratulations upon the present position of trade. True, there was no ground for despondency, and they must still continue to hope; but they had been hoping for five or six years, and they all knew the old saying, "Hope deferred maketh the heart sick," and he was afraid that these words were rather applicable at the present moment. But though the general condition of trade was by far from being what they wished it, there was one branch of our national industry about which there was no mistake, and which he thought, if his opinion were credited, left little to desire, and that happened to be the industry in which they were all interested, and many or most of them personally engaged—he meant the shipbuilding interest in this country. He had seen it described, and he believed pretty accurately, as being at the commencement of this year in a state of feverish activity, and the only possible point that anybody could urge, was that it might be a little too well, for they all knew that when they had a plethora of tonnage it meant low rates of freight and disappointment and loss. He trusted that that might not be the case in this instance. But it might be well to be reminded of the magnitude and importance of the shipping interest in this country. There had been invested in the shipping interest in this country one hundred millions of money, and there were employed two hundred thousand men, who earned 10 millions of wages annually, and besides these there were one hundred thousand men employed in our shipbuilding establishments and marine engineering works, earning wages to the annual amount of seven millions of money. He thought he was justified in calling this a mighty industry. In peace the shipping interest in this country largely fed our teeming multitudes of working men.

The shipping was the most important national industry, with the one exception of agriculture. So much for its importance in peace. But they were aware that the foresight of governments had secured for the service of the country, both at the period of construction, and afterwards, the service of those magnificent steamers which form the great ocean liners which convey all the vast commerce to our shores. Their decks were strengthened and they were capable of carrying heavy guns, and would be manned by seamen trained to the use of those guns. They might picture to themselves the start that this would give us supposing they were to be engaged in a war directly with any one or two great maritime nations in the world. He ventured to think that that was a start in which they would find considerable difficulty in catching up. This mighty industry was in a state of very great prosperity, and he would give them a few figures to show them. He would speak of the northern ports, because he was personally acquainted with them. He found the Clyde held her honoured position at the head of the list, having built last year one half more tonnage than she did in 1879, and 1879 was a very fairly active ship-building year all over the kingdom. The Wear built one-third more than in 1879; the Tees more than 50 per cent. increase over 1879 ; the Tyne only built one-tenth more, and she actually built 21 vessels fewer, but she built upwards of 10,000 tons more shipping than in 1879. Now that was important, because it showed that the efforts of our shipbuilders were directed to larger and more powerful and consequently swifter vessels. The figures were as follows :—The Clyde built in 1879, 191 vessels with 168,460 tons ; in 1880, she built 209 vessels and 236, 579 tons. The Tyne built in 1879, 130 vessels and 139,843 tons in 1880 she built 109 vessels only, but with 149,082 tons. The Wear built 65 vessels in 1879 and 92,176 tons, and in 1880 77 vessels, with 116,227 tons. The Tees built 25 vessels, with a tonnage of 31,756, and in 1880 38 vessels, with 48,506 tons, and the value of the vessels in the north-eastern ports built last year amounted to seven millions of money. Just to illustrate the strides that were being made in our shipbuilding establishments he would give one illustration. There was a little port called Blyth which the other day was only known as a coal port. There was launched a fortnight ago from that little port a fine powerful steamer of 2,500 tons, and classed A1 at Lloyd's, and that was the sixth vessel turned out from that active establishment within the last twelve months. No doubt the cheapness of material would afford some explanation for this remarkable activity, and he had gone somewhat closely into the prospects of shipping and the orders received by different establishments, and he had come to the conclusion that the only relaxation of this remarkable activity would be caused by the rise in the price of material.

A writer in the *Economist*, writing on the 5th February last, said he had ascertained from documents which had never been contradicted that there were at that moment building in the various shipbuilding establishments in this country no less than 650,000 tons of shipping under Lloyd's rules, and in addition to that there were 150,000 tons more not under Lloyd's qualifications, making a total of not less than 800,000 tons of shipping in course of construction in February last. Now there was another remarkable statement made. Mr. Pearce delivered a lecture in Glasgow a short time ago, and he brought out a remarkable fact that our steam fleet had increased since 1850 from 1350 vessels to 6690 vessels, representing 2,730,000 tons of shipping, or one million more tons than of all other steamships of the world put together. He was therefore justified in saying that we held a very fair position in the carrying trade of the world, and might justly be called the shipbuilders of the world. It might be interesting to follow this up by reference to our relative position to other great maritime nations, friendly and rival, in this mighty competition in this matter of ocean carrying. He would take his figures from an able writer in the *Atlantic Monthly* who was calling attention to the serious position of American shipping at this moment. He said our ships actually carried less trans-oceanic freight than they did three years ago, and far less than at any time during the last thirty years, the period of the Civil War alone excepted. In large ocean sailing vessels America holds a fairly good position, and England stands first on the list with 1,276 ships out of a total of [4,682. America stands next with 884. Norway is very close to America with 882.

France has only 57. That probably might account for that remarkable commercial policy upon which France appeared to be embarked at this moment, upon which he would say a word shortly. But when they turned to the ocean steam tonnage they were in a very different position indeed. There was a total of 590 steamers engaged in the trans-oceanic trade, and of that number England had 447 and America had only 46, and of that number 14 only were trans-oceanic strictly speaking, 32 running to the West Indies and South America, which might be called the American coast trade. The writer went on to say that the tonnage of the American Mercantile Marine might be thus estimated: 25 years ago the United States carried 75 per cent. of their own trade in their own ships. Steamers are monopolising the carrying trade, and of the 156 millions' worth of produce exported from New York to England, 140 millions' worth was now carried by steamers. There had been published a Parliamentary paper or report by Sir E. Thornton, relative to the measures submitted to Congress for assisting the shipping interest of the United States, and there is a statement made to the Senate of the United States by Mr. Beck, the Senator for Kentucky, on this subject. He says there is not a single iron sailing vessel to-day bearing the American flag, while iron ships are commanding much higher rates of freight than the best wooden ships, and a very large proportion of the heavy tonnage of the world is yet carried in sailing ships. There is not a single American steamship that crosses the Atlantic Ocean from the great port of New York, and there is not likely to be for years to come, unless we repeal our navigation laws. Thus there was this very remarkable circumstance. Mr. Beck said that while the Americans built in 1879 43,000 tons of registered tonnage there were sold to foreigners 37,000 tons, abandoned 24,000 tons, and lost 87,000 tons, making a total of 148,000 tons. Comparing the loss with the tonnage built, they would find that the losses were double the amount built. Now their lowest varied from 70,000 to 100,000 tons per annum, and they had at the stocks no less than 800,000 tons of shipping.

These were stern facts, and the fact of the matter was that America had protected her commerce of the sea, and her only chance, as Mr. Beck said, for the Americans to recover the position to which they were entitled was to free their shipowners and allow them to purchase their ships in the cheapest market; and if they did that he did not think they should have much ground for alarm, because no one could doubt that we could construct cheaper and better ships than any nation in the world, and the consequence was that, if the navigation laws of America were swept away, our shipowners would receive large orders from America. There was one remarkable statement of Mr. Beck's with reference to the grain fleet. The great bulk of our supplies of food from abroad came from America, and Mr. Beck says:—"The grain fleet despatched from New York last year numbered 2,987 vessels, carrying 102,312,568 bushels of grain, of which 1,075 were steamers carrying 42,426,535 bushels, the remaining 1,822 being sailing vessels carrying 59,892,033 bushels. All of this tonnage includes not one American steamer, and only 74 American sailing vessels. It is estimated that over one hundred million dollars are paid for foreign vessels in the shape of freight, and the great bulk of 75 per cent. is paid to England." The great event of the past year had been the great progress and the immense development of the steel manufacture, and its increased application to shipbuilding purposes. A deputation from the Institute had been at Glasgow, and nothing more delighted and impressed the deputation than the magnificient establishment of the Steel Company of Scotland. They saw an ingot of steel drawn from the furnace and converted in one heat into a boiler shipping plate, as bright as a mirror, a miracle of science and ingenuity which he did not think could well be equalled.

They had an opportunity also of visiting the *Servia*. Her tonnage was 8,500, and she was calculated to carry 3,000 tons of deadweight; she carried 2,000 tons of coal and 1,000 passengers, and she was estimated to steam 17½ knots an hour, and in that connection he might mention that the *Orezon* had crossed the Atlantic in seven days and eight hours. There were two lessons to be derived from that. One was that high pressure was not a source of danger, and that steel was a source of great safety to life, and was an invaluable material for shipbuilding purposes, combining as it did strength with lightness, and great elasticity besides. He knew that some high authorities thought that steel was the material for the future, both for our merchant and for our war vessels, but at the same time they must remember that price has a great deal to do with material, and the present price of steel would probably for some time to come be a serious impediment in its employment for the ordinary ship and rougher description of merchant vessels; but these were eminent authorities, and he was rather disposed to be with those who considered that the days of iron for shipbuilding purposes were numbered. He wished to quote a fact from the chairman of the Cunard to show the advance in Cunard ocean steamers. He said that when the *Britannia* made her first voyage, forty years ago, she measured 1,139 tons, cargo capacity 225 tons, and she steamed 8½ knots. He had given them the dimensions of the *Servia*, and she was calculated to steam 17½ knots. Well, that was no slight progress to be made in forty years.

He had alluded in passing to the French bounty system, which had lately been passed by the Senate, and to show the determination and the unanimity of the French nation upon the subject, that motion was carried by 265 votes to 5. He did not wish to attach much importance to this bounty system which France had adopted. They all knew that bounties were taxes upon the community for the benefit of the few. They knew that bounties were enervating, because they taught or induced those who received them to trust more for profit to the action of the bounty than to their own enterprise and intelligence. But, at the same time, so long as the majority of the nation chose to pay the piper it would be so; but it would not do for British shipowners to view this matter with entire indifference, and he could show them reasons for that. The French bounty operated in two ways. It was a bounty upon the first cost of the vessel, and the amounts had been variously estimated to very nearly one-fifth of the cost. Supposing a vessel to cost £50,000, the bounty would amount to something very near £12,000. But there was another branch of it. There was a bounty upon the navigation of the vessel amounting to one franc and a half per registered ton per thousand miles run on any direct line. Now, that had been calculated to amount in one year to 17½ per cent. upon the first cost of the vessel; and he would put the navigation bounty at 12½ per cent. more upon the navigation which amounted to no less a sum than 30 per cent. of the capital invested in that ship in one year. The effect of that appeared to him to be to put absolutely at least half that amount into the pocket of the shipowner in the shape of profit; and it was very like handicapping a superior horse in a race by putting two stones more upon his back, which was sure to give the advantge to the inferior horse. This was a great epoch in the history of shipbuilding in this country, and he thought he had proved that the condition of that industry left little to be desired.

His lordship concluded his address as follows :—"To what have we to look to maintain this proud position, even, if it be possible, to improve it, as the great ocean carrier of the world. We cannot look to bounties; we cannot look to subsidies; we cannot look to protective or retaliatory measures of any sort or kind. All this sort of legislation and these devices belong—or, rather do not belong—to that commercial policy which the nation has solemnly and deliberately adopted. We cannot look to artificial means, but we can look, and we shall look, with a confidence which the experience of the past completely justified, to the energy, and the pluck of our shipowners, to the ingenuity and skill, and educational and infinitive powers of our naval architects. We must look to them for increased mechanical appliances for the saving of labour, both in our shipbuilding establishments and in the navigation of our vessels at sea. We must look for economy of fuel in the use of improved compound steam machinery, and consequently a larger cargo carrying capacity in our vessels. We must look to them for increased speed and punctuality in navigation, and greater facilities in loading and discharging cargoes, and last, but certainly not least, we must look to greater care in the conduct of experiments upon designs in our shipbuilding establishments in order to bring ingenuity and theory to the test of practice. These are the objects and purposes of this Institution and it is in the fulfilment of this great purpose that you will gain for yourselves that to which I think you are fairly entitled, the title, namely, of one of the most useful and practical institutions in the country."

ON THE PECULIARITIES OF BEHAVIOUR OF STEEL PLATES SUPPLIED FOR THE BOILERS OF THE IMPERIAL RUSSIAN YACHT, "LIVADIA."

By W. PARKER, Esq., Chief Engineer Surveyor of Lloyd's Register; Member of Council.

[Read at the Twenty-second Session of the Institution of Naval Architects, April 6th, 1881; the Right Hon. the Earl of RAVENSWORTH, President, in the Chair.]

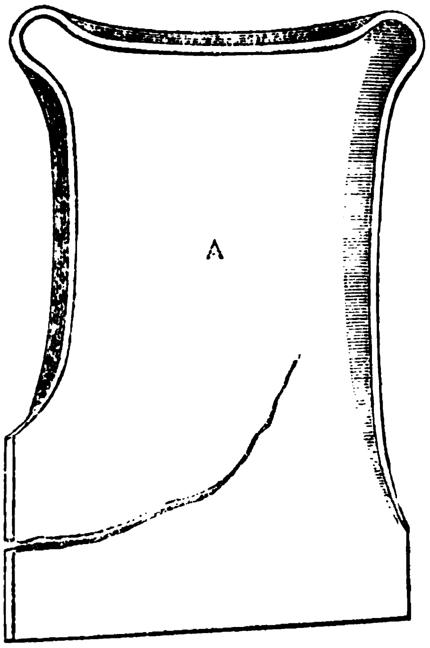
AT the annual meeting of this Institution in 1878 I had the honour to read a paper on the "Use of Mild Steel for Marine Boilers," and I then ventured to shadow forth that when greater care and attention came to be bestowed by our workmen in the manipulation of this material it would to a great extent, if not altogether, take the place of iron for such purposes. At that time there had been only two marine boilers of the modern form made of mild steel, but the manifest advantages this material offered over iron rendered its extensive application evident. Its great strength enabled a reduction to be made in thickness to the extent of 25 per cent. from that required in iron, or keeping the same thickness an increase of pressure of 33 per cent. Its great ductility and general uniformity had also, it will be remembered, been demonstrated by innumerable experiments embodied in papers read before this and kindred institutions.

A few statistics on the progress of the use of steel for marine boilers since the date above mentioned may not be without interest. Within the twelve months subsequent to that date 120 steamships had been fitted with boilers made of this material, and during the same period in the following year 280 vessels had thus been fitted, representing over 600 boilers, while up to the present time no less than 1,100 steel boilers have been constructed, and are now in use in steam-ships, representing a total weight of over 17,000 tons of material.

In the days of its early application two points remained open to doubt by many people, and were the cause of some hesitation as to the development of steel in this direction. One related to corrosion, which does not properly come within the scope of this paper, and the other related to the possibility of brittle steel plates finding their way into boilers, and thereby becoming a source of danger. On the latter point I may state at once, on my own experience, and on the authority of all the Engineer Surveyors of the Society to which I have the honour to belong, that not one single instance of a *brittle* steel plate has come under our notice during the manipulation of these 17,000 tons of steel; and it was not until the peculiar behaviour of the plates of the *Livadia's* boilers occurred that we had any fear on the score of brittle plates.

During the construction of these boilers, and especially during the first year, we often heard of mysterious fractures in steel plates which had stood all the tests required, been rivetted up into their places, and had then, as it was termed, *cracked without being touched*. A great number of these cases have been investigated, and in every instance they have been clearly traceable to improper manipulation of the material, and the plates in the vicinity of the fracture were found to be perfectly ductile after the fracture had relieved the strain upon the material. These cases were quite as numerous in steel manufactured by the Siemens process as by the Bessemer process. Figures A and B will show two plates which have thus torn, and which had been locally heated for the purpose of flanging.

Bessemer Steel.



Tube Plate of a Marine Boiler.

Fractures of this kind at one time used to cause some anxiety, and they have been over and over discussed at meetings of this and other institutions. They were clearly shown to be due to internal stresses set up in the plates by improper manipulation, and under certain conditions a tearing action was set up. As Dr. Siemens put it at the meetings of the Iron and Steel Institute in 1879: "A tear meant applying the whole of the force available upon absolutely one point of the metal. At that one point the metal might be capable of stretching even 50 per cent., but this would not save it, inasmuch as the force was confined to a point. At that point it would tear, and afterwards at another point, and so on. All these mysterious fractures reported might in nearly all cases be attributed to tearing action, which was generally set up at rivet holes if the rivets at those holes took more than their due proportion of the strain." Another illustration given by Dr. Siemens was that of a strip of india-rubber slightly nipped with a pair of scissors, and then stretched, when it would tear right across from the point of discontinuity.

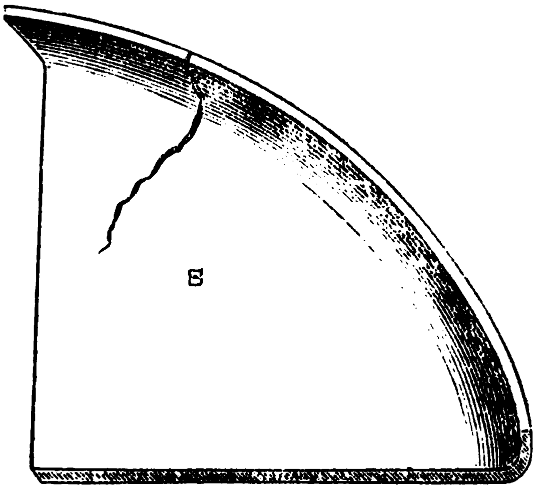
Now I may state at once that the fractures of the steel used in the boilers of the *Livadia* are entirely different from anything we had previously had experience of, and, what is more, we have still later experience of other steel behaving in the same way, and I think the time has come when steel-makers must sift the matter to the bottom, and not only find out the cause, but find out the remedy.

When it became rumoured that the steel used by Messrs. John Elder & Co. in the construction of the boilers for this vessel had given way while the boilers were under hydraulic test, I obtained permission to investigate the matter as thoroughly as I could, as it was felt that unless the reason of the failure in this particular instance was ascertained, the uncertainty as to its cause might not only retard the more extended use of mild steel, but would throw considerable doubt upon the safety and efficiency of boilers already constructed of this material.

Messrs. John Elder & Co. kindly afforded me an opportunity of inspecting the boilers which had ruptured, and in addition to this they very willingly gave the fullest information in their power bearing upon the case, and were good enough to send to London a large portion of the plates which had actually fractured, so that experiments might be made thereon. I also had an interview with Messrs. Charles Cammell & Co., of Sheffield, the manufacturers of the steel in question, and Mr. Alexander, on the part of that firm, stated that they were unable to account for the failure of the material, and in the interests of every one concerned would like to have the matter fully and impartially investigated.

It appears that the plates were specified to be Messrs. Cammell's subcarburised steel, made by the Siemens process, each plate to have a tensile strength of not less than 26 and not more than 30 tons per square inch, with an ultimate elongation of 15 per cent. in a length of 6 inches. In all there were 154 plates supplied, and from these 219 pieces were cut for bending tests; the cold bending and temper tests were made—and were nearly all satisfactory when made—from the rough shearings, and in those cases where the rough sheared pieces broke before bending to the required curve, duplicate test pieces were planed and properly prepared, when they all proved to be satisfactory. There were also 14 tensile tests made at the works, the tensile strength varying between the limits of 26·1 and 28·3 tons per square inch, the elongation in 8 inches varying from 27·3 to 34·3 per cent.

Siemens Steel.



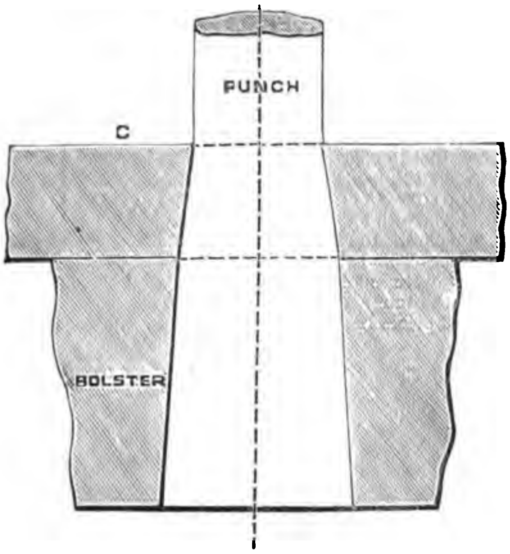
Back End of a Marine Boiler.

On the arrival of the plates at Glasgow, Messrs. Elder, for their own satisfaction, had some check tests made, which practically corroborated those previously made at the steel works. The details of these tests are shown in Table B. It will be seen from these tables that so far as tenacity and ductility are concerned the plates appear to be all that could be desired.

The *Livadia*, it may be mentioned, was intended to be fitted with eight double-ended and two single-ended cylindrical boilers, each of 14 ft. 3 in. diameter by 16 ft. long and 8 ft. 6 in. long respectively, constructed to work at a pressure of 70 lbs. per square inch, the shells being of steel, and the internal portions of iron. The shells were $\frac{3}{4}$ in. thick, made in three courses of plating—lap-jointed, treble-riveted in the longitudinal seams, and double riveted in the circumferential seams, as shown in Fig. 4 appended, and would, I may observe, be eligible, by the Rules of Lloyd's Register for determining the safe working pressure in marine boilers, to work at a pressure of 75 lbs. per square inch.

Judging from the results of investigations into previous fractures, the first inquiries that would naturally occur to anyone were, whether the plates had been punched, whether they had been annealed after punching, whether they had been locally heated and if so whether they had subsequently gone through the process of annealing. On visiting the works of Messrs. Elder & Co. I was informed that the plates were all punched, the holes being about $\frac{1}{16}$ in. less diameter than that of the rivets, then slightly heated and bent to their required curvature, and afterwards put together and the rivet holes rimed out fair to the finished size in place. Fig. C gives a full sized sketch of the punch and bolster employed in the present instance.

Figure C represents the Punch and Bolster used by Messrs. Elder.



I was also informed that while under this treatment one of the plates accidentally fell from the slings on to a piece of metal which indented it considerably, but did not crack or injure it in the vicinity of the indentation, but it was observed that the plate had cracked at a number of the rivet holes. Messrs. Cammell were in consequence communicated with, and Mr. Alexander, their representative, who examined this plate, gave it as his opinion that the plates had all been injured by punching, and should be properly annealed to restore the material to its normal condition. Accordingly the plates were all sent to the maker's works at Sheffield, and annealed in a furnace which had been specially altered for this purpose. A sketch of this furnace, and of the position of the plates while being annealed (see Fig. 1). The plates were afterwards returned to Glasgow, and riveted up in their places, and the boilers completed without any further cause for alarm.

On subjecting the first boiler to the hydraulic pressure, before the test pressure of 140 lbs. per square inch was reached the boiler shell tore asunder in three places, the cracks appearing to have started amongst the rivet holes of the longitudinal seams, and to have extended at the back of the rivet holes across the plate (*vide* Fig. 4). In the second boiler, which it was intended to test, the shell plates were found to be cracked in a similar manner behind the rivet holes, *before any water had been put into the boiler*. Mr. Bryce, the manager of the Engineering Department of Messrs. Elder's works, at once gave instructions to cut the whole of the steel shells from these boilers, and they were replaced by others made of steel manufactured by the Steel Company of Scotland. These plates, which were worked in precisely the same manner, gave no special trouble in working, and the boilers proved to be satisfactory under test.

On examination of the cracked or torn shell plates they were found to be extremely brittle; large pieces were easily broken off in my presence by one blow from an ordinary sledge-hammer. In other words, here was a material which had satisfactorily withstood all the mechanical tests recognized by Lloyd's Register, the Admiralty, and the Board of Trade, as sufficient to determine its suitability for the purpose for which it was being used, and was now shown to have become as brittle as cast iron, or even more so, after having apparently undergone only the working usual in boiler-making.

Many causes were hastily assigned for the remarkable change the steel had apparently undergone during manipulation, and all more or less plausible. These possible causes were investigated as rigidly as was possible.

1. It was suggested by some that the steel contained too much silicon, sulphur, or phosphorus, or that perhaps the carbon was too high, and that chemical analysis would clear it all up.
2. It was suggested by others that the material could not have been made by the Siemens process, but must have been produced by the Bessemer process, and possibly had been overblown.
3. It was suggested also that the material might have changed its nature during the process of annealing, and that brittleness might have been induced by the absorption of gases in the annealing furnace, which would be contained in the material in an occluded state; or that perhaps the edges of the plate had been burnt during the process of annealing.
4. It was finally suggested that the cause might be traced to the action of punching or riveting, assuming all the tests that had been made to be *bonâ fide*.

Accordingly chemical analysis was resorted to as being likely to throw some light on the subject, and I must say that in this instance I was most fortunate in obtaining the co-operation of several of the most eminent metallurgists and chemists in the kingdom, who have kindly furnished me with careful analyses of samples of the material, and have also given me valuable hints and information in the course of this investigation. The results are set forth in Table C, which also contains the analyses previously made for Messrs. Elder by the Glasgow City Analyst, together with analyses of steel of different Companies' manufacture which has not given trouble in working. Although there are one or two points of difference in the results they may be said to fairly agree, and they do not show any reason why the material should behave in an anomalous manner; and considering that the raw material used was thus shown to be of suitable quality, it became necessary to look either to the mechanical treatment by which the ingots and slabs were converted into plates, or to the subsequent treatment which the plates have undergone.

When the portion of boiler shells was received in London one of the fractured plates was separated from the other plates by carefully drilling out the rivets connecting them, and several strips were sawn cold out of the failing plate for testing purposes from the position shown in Fig. 3. Of these strips two each of 1 inch, 1½ inch and 2 inches width respectively were tested by Professor Kennedy, of University College, for tensile strength and elongation, with the results shown in Table IV., Specimens *B*, *C*, *D*, *E*, *F*, and *G*. The results seemed to be everything that could be desired so far as tenacity and elongation are concerned, *but the fractures appeared to be altogether different from those usual with good steel*, the distinct signs of lamination, the peculiar colour, and the crystallization being entirely new features.

Other strips about four inches wide (specimens *a*, *b*, *c*, and *d* in Fig. 3) were taken and subjected to bending tests. They were each found to be extremely brittle in proximity to the rivet holes, breaking across at the holes with one blow from the hammer, while but a short distance from the holes the strips bent cold to the same curvature as would be expected in ordinarily good steel; and on one of the strips being raised to a white heat and allowed to cool, it was bent nearly close without any signs of fracture.

As already stated, the holes in the original boiler shell had been punched and then rimed out slightly to make them fair, and the plates afterwards annealed. As so small an amount was rimed out from them, it would happen that in cases where the holes were unfair at first, the whole of the riming would be taken off one side of the hole, leaving the other side in the same condition as when punched. This is seen in several of the holes from which the rivets have been carefully removed, but as the plates were annealed after punching, previous experience would warrant the supposition that all injury from punching would be thereby removed.

In order to ascertain the effect of punching on the material, several holes were punched in these strips, and without exception it was found that the strips immediately became as brittle as the material in the vicinity of the original holes in the boiler, one blow being in every case sufficient to break them across the breadth of 4 inches, and no perceptible bending being produced before fracture. Pieces were then taken and holes punched therein; one piece was annealed after punching, in another the holes were rimed out ⅛ inch larger in diameter than the large side of the punched holes, and in a third piece the holes were drilled. In each case these samples bent to right angles across the holes without fracture. Similar pieces were prepared from steel made by the Steel Company of Scotland, the Landore Siemens Steel Company, and the Parkhead Steel Company, but in these cases the punching seemed scarcely to affect the bending capabilities of the material, the strips with punched holes bending to the same extent across the holes as the unpunched strips.

These experiments were afterwards corroborated by cutting off parts of the original joint of the plate from which the rivets had been drilled out, and striking each piece light blows with a hammer, which broke them easily into small pieces, but on the material from the same locality being annealed it was found to bend almost double even across the holes (*vide* Fig. 3, specimens *e* and *f*). Analytical and Consulting Chemist.

City Analyst's Laboratory,
138, Bath Street, Glasgow,
4th June, 1880.

of the unpunched plate was also taken and holes punched in it of the same diameter and pitch as those in the boiler seam, and it behaved in a precisely similar manner (*vide* Fig. 3, specimen *J*). A piece of plate was annealed before the holes were punched; it was also nearly if not quite as brittle as the unannealed piece, and a further piece annealed after punching, was found to bend well (*vide* specimens *K* and *L*).

Table D.—Analysis made by an Eminent Metallurgist on a Sample of the Steel which Failed in the Boilers of the "Livadia."

Shavings about $\frac{1}{16}$ inch thick were taken off in successive layers through the thickness of the plate, and carefully analysed for Manganese, Carbon, Phosphorus, and Sulphur, with the following results:—

	Mangan.	Carbon.	Phosphor.	Sulphur.

Four strips were then cut diagonally between some of the rivet holes of the boiler as shown on Fig. 3; one of them broke into three pieces with a blow from a hammer whilst trying to straighten it, and a similar piece after being annealed bent nearly close without fracture. A third piece was planed parallel, the punch marks being removed, and on being subjected to tensile test it was found to have a tenacity of 29·25 tons per square inch, with an elongation of only 4·7 per cent. in 5 inches (*vide* Table E, specimen *H*). The want of elongation observable in this specimen, combined with the curvature after testing, indicated that the stress caused by punching was not entirely removed, and accordingly a fourth strip was planed smaller, the metal being planed off at least ⅛ inch from the edges of the holes. This piece showed a tensile strength of 30·58 tons per square inch with an extension of 16·8 per cent. in 5 inches (*vide* Table E, specimen *I*). The elongation in this piece was more satisfactory and the reduction of area was considerable, but this piece was also curved after testing, showing that even the comparatively large amount planed off did not entirely remove the metal affected by the punching. These experiments conclusively proved that the metal in the vicinity of the rivet holes was considerably injured, being rendered quite brittle, that annealing restored it, and that other steels of apparently the same chemical composition and standing the same mechanical tests were not so affected.

It being thus found that punching holes in the plates made them extremely brittle, some specimens were prepared to ascertain the effect of that operation on the tensile strength of the material. A piece of plate was punched with two rows of holes and then sawn into strips, each strip containing two holes. In one strip the holes were rimed out, another was annealed, and the third was plain punched. On being tested, the rimed specimen broke at a stress of 27·6 tons per square inch, with an elongation in 8 inches of 7·5 per cent.; the annealed specimen stood 26·6 tons per square inch and stretched 6 per cent. in the same length; and the plain punched piece broke short off with no extension under a strain of 18·4 tons per square inch (*vide* Table E, specimens *g*, *h*, *i*).

These experiments merely corroborate those already published by various authorities on the effect of punching, riming, and annealing steel plates made by either the Bessemer or the Siemens process, namely, that plates above ⅝ of an inch thick punched with the largest diameter of bolster as compared with the diameter of the punch, consistent with obtaining a fair hole, lose about 30 per cent. of their tenacity, while riming out the holes or annealing the plates after punching restores the material to its original strength.

A narrow strip was cut from the plate next to that previously experimented upon, from a part of the plate remote from any of the rivet holes, and it was found to be extremely brittle. The fracture of this piece presented a very peculiar appearance.

The outside sixteenth of an inch on one side presents mirror-like facets from one-eighth to one-quarter inch wide, the rest of the fracture being of a fine granular, crystalline, but striated appearance. This outer layer is very soft, being easily nicked or cut on the edges by a penknife, and, as will be observed from the analysis, it contains no carbon, while the layer immediately below this contained a little, the inside of the plate containing more. This fact may perhaps account for the difference between the several analyses.

It would thus appear probable that this part of the plate had lost some of its carbon by a process the inverse of cementation, either by being overheated at one corner while in the form of an ingot or slab, or by a similar overheating while being annealed.

In further confirmation of the foregoing analysis, I have the results of another series of experiments on a piece of these plates from a gentleman of high authority, who has taken the greatest interest in this investigation. He took a portion of the plates about eight inches long and four inches wide, and after having carefully removed all the rust from the outside by grinding, he had successive layers planed off from one side to the other. Each layer was one-sixteenth of an inch in thickness, and the layers were numbered in succession as they were planed off. The results, as will be seen from the accompanying table, are extraordinary.

I had intended to pursue the question of the possible absorption of gases on this steel, but I regret to say I have been as yet unable to make much progress in that direction. It is pretty clear, however, that there is a fruitful source of inquiry in this direction which I hope will yet be taken up and pursued by some one more capable of doing so than I can pretend to be.

All the other specimens that were tested for tension presented an entirely different appearance from those of steel that has worked well; some of the fractures were crystalline whilst in the same fracture other portions were silky, others were filled with distinct laminations and cracks, and the colour of the fractures was quite different from the beautiful dark grey so marked in specimens of good steel. The peculiar appearance of the specimens suggested the idea that the plates might have been produced by rolling them from a slightly spongy ingot, the vacuities or air cells in which had been closed up during the operation of hammering and rolling, but the sides not perfectly united. It was also suggested that the plates might not have had sufficient mechanical work upon them, either by being cast in flat ingots and rolled direct into plates, or by cogging the ingots down to the thickness of the slabs instead of hammering them. Accordingly a piece cut from the fractured plate was raised to a red heat and rolled to half its original thickness (Fig. 3, Specimen *X*). Strips were then cut from this ⅜-inch plate and punched with holes ½-inch diameter, being one-half the size of those in the ¾-inch plate. This extra work on the material seemed to raise its ductility appreciably, the strips being found to bend well after punching, several of them bending to right angles and only one of them breaking short off, while none of them showed such extraordinary signs of brittleness as were observable in the material when of the original thickness. Three pieces tested for tensile strength after rolling broke under a stress of 33 tons, 34·25 tons, and 32·3 tons per square inch respectively, with an elongation in 8 inches of 12 per cent., 11·25 per cent., and 17·5 per cent. respectively, the last-mentioned specimen being annealed (*vide* Table IV., Specimens *X*). It was also observed that the fractures in these specimens were fine and silky, and had no appearance of lamination or crystallization such as existed before the material received this additional rolling, while the colour was precisely the same as that of specimens of steel that has given no trouble in working. In fact, the extra work bestowed upon the plates seemed to render them satisfactory. In order to corroborate these results a second piece was rolled down to the same extent and subjected to similar treatment with the same results.

The extreme brittleness of these plates, after holes are punched in them, would thoroughly explain the failure of the boiler under hydraulic test, had the plates not been annealed after being punched; but seeing that they were so brittle at the joints when in the boiler and that they became perfectly ductile when re-annealed, it is evident that they could not have been properly annealed in the first instance, after punching. This raises the important question, whether it is possible to anneal very large plates so as to thoroughly set at rest any strains induced by punching or local heating, especially when the plates are bent, and are therefore liable to become more intensely heated in one part than in another; and it shows the advisability of drilling all holes in such plates, and so avoiding the necessity for annealing.

The conclusions arrived at from this investigation may be summarized as follows:—

I.—That there is nothing in the chemical analysis of the material, beyond the want of uniformity described, to account for its behaving in an anomalous manner, and that, so far as can be discovered, the raw material used seems to be of a suitable quality.

II.—That the material as first rolled into plates stood the tests required by the specification, and also those prescribed by Lloyd's Register, the Admiralty, and the Board of Trade, the tensile stress, the elongation, and the bending tests being quite satisfactory.

III.—That the tensile strength of the material was not reduced by punching to a greater extent than is usual with mild steel, but that the plates when punched—whether one hole in a strip or several holes along the edge of the plate—became *extremely brittle* for some distance from the holes.

IV.—That the appearance of the fractures, especially in those samples broken by tension, showed that the material had not had sufficient mechanical work bestowed upon it, a number of minute laminations, cracks, and longitudinal splittings being distinctly visible in the specimens; and this defect, together with punching, made the material entirely unfit for employment.

V.—That further working of the material, to the extent required to reduce its thickness to one half, appears to have nearly, or entirely, eliminated the cause of the brittleness.

VI.—That, in order to avoid the use of similar plates in future, the fractures of test pieces should be carefully observed, and should any of them present an unusual appearance, further bending tests should be made on strips having holes punched in them of a diameter about 1½ times the thickness of the plates.

Since completing the foregoing investigations, and arriving at the conclusions set forth—indeed, since the preparation in great part of this paper—it has been my duty, in company with my colleague, Mr. John, to inquire into another series of failures of plates, this time used for shipbuilding purposes. The material had been supplied to Messrs. W. Denny & Brothers, Dumbarton, by the West Cumberland Steel Company, Workington, and as some of the plates had fractured in a somewhat alarming manner, we were directed by the Committee of Lloyd's Register to investigate the subject.

We were shown a couple of these fractured plates at Messrs. Denny's yard, one being a bow plate, the other a plate from above the boss which cracked through the landing edge. We had a strip about 3¾ in. broad cut from the latter, the strip being in the rough, sheared on one edge and punched on the other. It was placed on an anvil, and when struck with a hammer broke off short. This plate was $\frac{19}{32}$ in. thick, and broke at a tensile strength between 31 and 32 tons per square inch, with an elongation varying from 20 to 25 per cent. Having broken this strip off short with a hammer in its rough state, we had its edges planed down to remove those portions injured by the punching and shearing, when it bent over to a radius of ⅞ of an inch without fracture. A ¾-inch hole was then punched in the same piece, and after this it broke again short off with a blow from the hammer.

It was evident from this that the material resembled in its defects the steel which failed in the *Livadia's* boilers. The specimens were sent to the Steel Works, and we discussed the matter there with Mr. Snelus, who most frankly admitted that the material was not such as it should be, or such as he would knowingly have sent out from his works.

We have no reason whatever to doubt that the material was made by the Siemens process, that the ingots were of a reasonable size, and that they were hammered down into slabs in the usual way. What the exact sizes of the ingots were, however, we could not ascertain, but we were assured that 12 inches was the minimum.

We tested another plate at the works that had been sent back cracked from Messrs. W. Denny Brothers' yard, and a couple of other plates which Mr. Snelus himself had rejected at the works. Two of these plates were $\frac{13}{16}$ in. thick, and had been made for boiler shell plates, and Messrs. Denny's ship plate was $\frac{11}{16}$ in. thick. We had shearings cut from these three plates, and in each case they broke off short when it was attempted to bend them cold with their sheared edges in the rough. These plates were all brittle, and it became a question whether they had become so in the process of rolling, either by being rolled too hot or too cold; or whether it arose from an insufficient amount of work having been put upon them. To test this it was arranged to cut the plates up into six equal parts each, and to roll them down in duplicate at three distinct heats. One set was rolled down at the ordinary temperature, another at nearly a white heat, and the other set at as low a temperature as it was safe to adopt without breaking the rolls.

TABLE E.

REPORT ON TESTS CONDUCTED BY PROFESSOR KENNEDY IN THE ENGINEERING LABORATORY, UNIVERSITY COLLEGE, ON SAMPLES OF STEEL CUT FROM THE BOILER PLATES OF THE IMPERIAL RUSSIAN YACHT, "LIVADIA."

* NOTE.—As the specimens were made, the 8 in. ength was between shoulders, and included fillets of ⅜-in. radius at each end. The extensions on 6 in. are therefore given in addition.

† NOTE.—It was particularly noticeable that these two pieces pulled themselves into sinuous curves. This indicates to some extent how greatly the material must have been strained by the formation of the rivet holes.

We then cut strips from these reduced plates for testing, and the results may be briefly summed up as follows :—

The thick boiler plates $\frac{15}{16}$ in. which were rolled down to $\frac{5}{16}$ and $\frac{9}{16}$ were found to have become ductile, and the rough shearings were capable of performing good bending tests, whether rolled down at an ordinary heat at a very high temperature, or at a comparatively low temperature, near a black heat. The plates rolled down at the ordinary temperatures, it is true, stood the tests best, but it was evident that the theory that a slight variation in the temperature such as would be at all likely to occur during rolling in practice would not account for the remarkable behaviour of the steel we were investigating.

In the case of the plate returned from Messrs. W. Denny & Bros.' yard, the effect of the rolling down was not so marked, but this might be accounted for in some measure by the fact that the plate was only $\frac{11}{16}$ thick to start with, and consequently did not get so much extra work put upon it as the two $\frac{15}{16}$ plates did.

Further tests were made in duplicate, all tending to show that with more work on the plates they improved, and that this was the case in spite of great variations in the temperature during rolling. The experiments also showed that when the plates were so rolled down they did not break off short when it was attempted to bend them across punched holes. In fact they bent to a considerable angle before showing signs of fracture at the holes, which then opened gradually, instead of going suddenly right across. I regret to say that we have since heard of further failures of this material in the same yard.

How far the greater or less amount of work done on plates in reducing them from the ingots is accountable for the failures and peculiarities which have recently come to light is a question of the utmost moment, and it is one which to my mind should be thoroughly investigated. I am aware that Mr. Webb, of Crewe, laid it down some years ago that the ingot should be at least twenty times as thick as the plate to be produced from it, and he had doubtless sound reason and experience to guide him in his decision. Whether, however, an inch steel plate rolled from a 24 in. ingot would be in the same condition as a half-inch plate rolled from a 12 in. ingot, is a question I am by no means sure upon. In more than one case during a recent visit to a number of steel works I had the pleasure to hear manufacturers express their perfect readiness to incur considerable expense in experiments rather than leave this question in its present unsettled state. I hope that feeling will become general. The remarkable variation in the distribution of the carbon, phosphorus, and other constituent elements is a point that must also be accounted for, and its true significance ascertained. And I would further add that the testing should be of a more varied and elastic nature than at present. The appearance of the fractures should be carefully watched, and where any departures from the well-known silky fracture common to good mild steel appears, the plates should be subjected to further bending tests on strips in their rough sheared condition, with holes punched in them, and in any other way that hereafter may be shown to be efficacious in discovering untrustworthy material.

I may add that in the case of most of the experiments I have described I have had the advantage of check tests almost in duplicate, which Mr. Kirk, of Messrs. R. Napier & Sons, has been good enough to make, and I have been fortunate enough to secure further check tests in other directions, so that I hope I may say with confidence that the results I have the honour to lay before the meeting are by no means isolated and unrepresentative ones.

In conclusion I have to express my best thanks to Messrs. J. Elder & Co., Messrs. Cammel & Co., Dr. Siemens, Mr. T. Vickers, Messrs. W. Denny & Bros., Mr. Snelus, Professor Kennedy, and many others who have rendered me most cordial and ready assistance in these investigations, and I must express my hope that instead of tending to create a prejudice against mild steel for constructive purposes, the facts I have laid before the meeting will tend rather towards a further improvement in its quality, and towards the removal of one of its last drawbacks, viz., its occasional, and not yet sufficiently understood, liability to fracture in a capricious and unexpected manner, under certain circumstances, while under others, it is capable of being bent double cold, and showing remarkable signs of ductility.

Mr. Kirk said he had been asked by Mr. Parker to make some tests, and he had done so. The first thing which came out was that the plates would bear very little manipulation. A strip about a foot long, slightly bent, would not bear straightening cold by gentle pressure. It cracked at once; but when heated and forged into a bar $\frac{5}{8}$ in. square it was so much improved that the bar could be bent cold on itself, so he thought that the material was good but the manufacture bad. He then took some Siemens-Martin plates, and tried to spoil them; he could injure them, but not make them as bad as the *Livadia* plates. Annealing might improve or spoil plates according to how it was done. He showed a sample strip of the original metal bent cold on itself without crack. A second sample, equally good, had been left in a forge furnace for twelve hours, the damper being down, and the air excluded; the plate was uninjured. Two other samples, heated in much the same way, but with the doors open and dampers up, so that a current of air passed through the furnace, were spoiled. A good plate could not be improved by annealing.

Mr. Thorneycroft said that if they would look at the drawing of the annealing furnace—Fig. 1—they would see that the plates had been so stacked on each other that uniform heating was impossible. The more work was put into steel the better. He used large quantities of thin steel—$\frac{3}{16}$ in., and it was usually tougher and better than thicker plates.

Dr. Siemens said, as one that was interested in the production of steel, and named also by the author as having given some attention to the cause of this extraordinary failure of the material, he wished to make a few remarks. The behaviour of the material composing the boilers of the *Livadia* was so extraordinary, and the results so contradictory, that it was certainly of the greatest interest that they should have it sifted to the very bottom. When the defective condition of those plates was first discovered, Mr. Parker kindly sent him a specimen of a piece of plate broken off short by a hammer, and the analysis which he had made showed that the metal was certainly irregular in its composition, but it gave a certain percentage of an element which he did not see represented on the author's table displayed on the walls, and that was silicon. The specimen which he had given him contained, certainly, a very considerable portion of silicon. Another analysis by eminent chemists had given, he was aware, different results. They had shown no silica; but if they looked upon the interesting table that had been placed before them, he thought they had quite sufficient hints given them to account for this great difference in analysis. Then they had in the same plate the carbon differing in the proportion of at least 1 to 2 between the outside of the plate and the inside of the plate, and they had phosphorus, a substance which was not easily oxidised when combined with metal distributed in the same irregular manner, and the same with regard to sulphur. Now the question arose—how could that very great difference in those constituents have arisen in the metal? Was it that the metal itself that the ingot contained was not composed of the same metal? or was it metal imperfectly fused and imperfectly distributed in the ingot mould; or had the metal, when being rolled into plate, been subjected to treatment whereby its chemical nature had been so completely altered, as would appear from the table on the wall? He could hardly imagine that in the same ingot, although there might be differences of composition found between one portion of it and another, that that metal had not been properly melted; differences of such extraordinary magnitude as that could possibly never occur, and he was therefore forced to the conclusion that the metal had been greatly injured in the after-process to which it had been subjected. Mr. Kirk had brought before them a very interesting experiment, showing how steel of undoubted good quality, when heated injudiciously, and heated for a length of time in a furnace, contained a large excess of oxygen—could be what they called in the iron trade "burnt." It would be interesting if they could have seen another column there, only he admitted that it would have been very difficult to show it. Of the amount of oxygen absorbed in the metal, he thought it would have been found that the place near the surface had absorbed a very considerable amount of oxygen, which assisted in the making it the brittle unreliable substance which it became when it was expected to do its work. It was stated in that Paper that every precaution was taken that when the plates, after punching, showed defects, they were taken back to the works to be annealed. Now, he was disposed to take great objection to that precedure. Mild steel should bear any amount of rough work in the cold condition without receiving the least injury. If by punching mild steel they lost strength he considered that they had a clear proof that the material was not what should be used. So far from losing strength, the very act of punching increases the strength of that material. In fact, any treatment to which mild steel was subjected, stretching it or punching it, squeezing it in any one place so as to alter slightly its form, the effect was invariably an increase of strength, and not a slight increase of strength either. It was, therefore, a practice with which he had little sympathy, that of annealing plates after punching. He would venture to say the metal used, if it were punched without being annealed, and if it were proper metal, should not require it. If the holes were afterwards bored to make the edges smooth it might be desirable to give more elegant work, but for the mere sake of getting strength and getting reliable work he did not believe that it was necessary that punching alone should give them the full strength of the metal when the work was put together. Therefore what they should know in order to judge this question more fully was the exact mode in which the metal was treated after it had been made—what size ingots were cast, and were those ingots hammered before they were rolled? If they were re-heated, as they undoubtedly were, what kind of furnace was used? Were they allowed, perhaps, to remain, as sometimes happened, a night in the furnace? He had known of workmen, taking offence at something or other, throwing down their tools and leaving the metal a whole night in the furnace. If metal was treated in that way it must be looked upon with great suspicion. Then again, Mr. Thorneycroft had alluded to the processes of annealing, which were sometimes adopted. I think there is great danger in annealing steel plates; and it was only necessary if that steel plate has been treated in a forge fire, if it had been heated partially in order to bend it, then annealing was necessary to bring it up as a whole into a natural condition, but if the metal had been worked cold he believed it better after having annealed it. This annealing was not always done in a proper and judicious manner. If one plate could be put into a well-heated furnace, and taken up rapidly, the temper which is necessary in order to put the particles at rest towards one another, and then taken up and allowed slowly to cool, there would be probably no danger arising, but if plates were heated up in an annealing furnace and when to bring the heat down to the bottom-most plate, a strong fire was applied to the uppermost plate, it was but natural that those plates were put to great danger. But the probability was that some of them would be overheated and that others would be heated all round at the edges, and not be uniformly heated, and any such process of annealing must be fraught with danger to the material produced. With regard to the process used, it was stated that the plates alluded to were made at the Cumberland Works, and were undoubtedly made by the Siemens process. Now this statement had been received authentically, but he thought there must be some little mistake about it, inasmuch as those works had only lately put up one furnace according to his system, and he was told by Mr. Snelus the other day that it had not been properly put to work. Therefore there must be some mistake about the process, not that he wished to imply that this could not have happened with steel manufactured by one process as well as by another.

Mr. Pence said, as a member of the firm who built the *Livadia*, he might say that they wrote to the West Cumberland Steel Company with regard to the plates of which the *Livadia* was built, and they received the answer that part were made by the Bessemer and part by the Siemens process; but they had not received any distinct answer as to which plates were used. He concurred with Dr. Siemens that the responsibility of making bad steel must be thrown entirely on the steelmaker; but he could not agree, however, with Dr. Siemens in the idea that working mild steel improved it. In all their experience they had no such evidence, and it would need very strong evidence indeed to convince him of it. Regarding the peculiarities of this steel he could only confirm the remarks made by Mr. John. The plate shown there was a plate from the vessel, and it had been screwed up and was right in every way, and the morning after it was screwed up it cracked in the manner shown in the diagram. Previous to those mishaps they had used 10,000 tons of steel, and they had had no mishaps of this kind. With regard to the fact that when the thinner steel was rolled the better it worked, he might say that the first steel from the West Cumberland Iron Company was then steel about three-sixteenths and a quarter of an inch thick, and it was used on a river steamer, and it stood a collision in a way which was perfectly surprising, and this encourged them to hope that the thinner steel would be the best, but they had been disappointed. The tests should be very crucial, and they should not be diminished in their severity, but rather increased. These mishaps to the *Livadia* had not shaken his confidence in the material, and the owners of the *Livadia* had determined to build their ships in future of steel. If they looked around they found 1,100 steel boilers working under conditions of great strain, and without any serious mishap, and he thought that these mishaps, instead of lessening their confidence, would make them more and more firm in insisting that steelmakers should give them the best steel, and punish the producers of bad steel.

Mr. Denny said that as regarded his plates part had been made by the Siemens-Martin process and part by the Bessemer process. He could not say which had failed. He had come to the conclusion that it was incumbent on himself and shipbuilders generally not to give orders to firms who supplied defective plates. This was the only way to compel steel makers to supply a trustworthy material; and he for one would never consent to take a plate from a firm which supplied untrustworthy metal. The steel makers must look to themselves. Working mild steel did not improve it. The plate referred to by Mr. Parker had been cottered up, and next morning was found broken. Thin steel—$\frac{3}{16}$ in. from the Cumberland Company's work stood splendidly. This opened his eyes to the fact that thin steel behaved differently from thick steel. In future tests ought to be increased in severity.

Mr. Riley thought the last remark of Mr. Denny was undoubtedly a just one—viz., that whilst attention was called so strongly to this failure, it was right that attention should be directed to the 1,100 boilers and the 17,000 tons of boilers steel now in existence where there had been no such mishap. As to the effect of the quality of iron used in making steel, if the iron taken into the furnace had an excess of silicon in its composition, undoubtedly the steel resulting would not be what was expected, even if the silicon should not be found present to any large extent. In these omissions might be found some explanation of the peculiar behaviour of this plate.

Mr. West said that 20,000 tons of steel plates had passed through his hands, and with comparatively satisfactory results. There were no failures even with the high tension steels, whose adoption he had advocated last year. They would have to be content with punched holes for ships, and he was of opinion that punching did not injure good steel in one sense. He had also found that if a strip of Bessemer steel were bent at right angles, and then straightened, its tensile strength would be augmented. He feared that in the case of the *Livadia* the original tests had been perfunctory. As for annealing the plates after they had cracked, it was locking the stable door after the horse had been stolen. A 22 in. ingot was quite large enough to make a $\frac{7}{8}$ in. plate out of.

Mr. Samuda remarked that in ninety-nine cases out of a hundred they had only now and then found a plate which was incapable of passing the ordinary tests of working processes which they used, but in those very few cases they had found, until the plate would break under the blow of a hammer, that it had been entirely restored to its natural position of ductility when it was properly annealed. Therefore, under circumstances, there were advantages in regard to annealing, but he quite agreed with Dr. Siemens that, as a general rule, they never used the annealing at all. His experience of working had now reached over twenty years, and it had been of every description of manufactured steel, and though no doubt the process had not yet reached the same perfection as that which was got by the mild steel, which they were now getting by the Martin and Siemens process, in all these cases they had found that a good reliable steel was able to be obtained when a sufficient amount of care was taken in the selection of the thing originally, and the manufacture of the steel. He had not gone into the question of the steel used in the *Livadia's* boiler, but as a general rule it must have been totally different from that which they had seen from either the Landore Company or the Steel Company of Scotland, or from the great manufacturer of steel in Germany, Krupps; all of which they submitted, without any difference whatever, to the same tests, and, as a rule, they came up to the very highest requirements and the greatest reliability that they could have with any materials. And the result of this investigation by Lloyd's, and the general observations in the room must go to strengthen the conviction, that while it was absolutely important that no one should relax in the smallest degree from requiring the greatest amount of perfection in the steelmakers, they should not be content with anything short of very best quality, and they should not allow prices to interfere with their desire to obtain it.

Mr. Martell held that while steel was better than iron, it would be foolish to shut our eyes to the fact that mysterious failures do occur. There was a mystery about mild steel which there was not about iron. The size of the ingot had a great influence. One steel manufacturer had tried to roll plates out of steel slabs, and had entirely failed. Mr. Webb, of Crewe, a man of great experience, said he could not get a sound plate from an ignot less than 24 in. square. That was an important statement. He could not restrain the expression of his astonishment at Dr. Siemens' assertion that punching did not weaken steel; it was contrary to all experience. Steel makers must not delude themselves by testing planed and filed samples, but rough samples, showing how the metal was handled in the shipyard. Confidence had been shaken, and must be restored by the steel makers.

Sir Spencer Robinson said that he had not lost any confidence in the mild steel as the right material for shipbuilding. The steel supplied to them by the Steel Company of Scotland had never failed under any circumstances. In the shipbuilding establishment in Hull they built several ships of steel, and a great many steel boilers, and they had not had one single case of failure that Mr. John described. On the contrary, their success had been complete in every respect, and they had none of those accidents, or cracking, or going wrong that had been described, and their steel was supplied by the Steel Company of Scotland. They had tested it over and over again. He had made many experiments of punching steel plates, and had found a loss of strength in punching which was restored in most cases by annealing. He knew that shipbuilders had to deal with steel in such a way that they could not always do otherwise than treat it by punching—they could not always bore it out. The materials that the shipbuilders used, and what they had a right to ask for from the manufacturers of steel was a material that punching should not affect and should not weaken. It would be a great mistake, and he should be very sorry, if the opinion went uncontradicted, and as far as possible unproved, that the punching of steel was a diminution of strength and not always restored by annealing. There were differences of opinion on this subject, and probably in all the cases there were some differences of circumstances which made the observations not exactly parallel and not exactly reliable. What was wanted was greater pains in the manufacture of steel, and greater care in the rolling down of the steel plates, and when that had been done and the proper work of the steel had been had recurrence to, everybody would admit that in a short time there was no material in the world comparable to the mild steel which might be had in this country.

Mr. Cowper, President of the Mechanical Engineers, observed, that many of those plates were very thick, and on the diagram there were eleven plates, one on the top of the other. Now, if they could imagine a pile of plates, placed 11, 12, or 13 inches high, either the top plate must have had too much heat, or too much fire, or the other plates must not have been properly annealed. It was quite impossible to heat those plates thoroughly through. Some of them would get too much and others not enough. With regard to the quality he saw by the table, that the carbon was ·149, the phosphorus ·069, the sulphur ·091, and the silicon somewhere about ·03. With those three last qualities added to the ·149, he did not wonder at the brittleness, and that an annealing furnace would not set it right.

Mr. Whyte, Assistant Secretary to the Navy, said, in the experiments which had been made in the navy they had tried samples sheard and slotted to shape. Under direct tensile strain they had not found a difference in the strength of the section where it was obtained by punching the edges, but there was a difference indeed when it came to forge tests. Then it was really too much to expect at haphazard to be able to deliver blows upon a forge test sample. When they came to forge tests he thought they should have some guarantee that they had no very unfair strains, and that other parts were not thus suffering.

Mr. Laird said, in their experience in making steel ships, they had only one instance of plate cracking, and it was in heating a straight plate in the furnace to bend it to the required angle, and the day afterwards it was found fractured, as in the case of the *Livadia*. Therefore, he was inclined to think that the heating had in this instance a great deal to do with the failure of the steel.

Dr. Siemens did not wish to say whether plates should be punched only, or whether it would be better to clean out the holes, but what he said was that in taking a strip of mild steel, he referred, not to the somewhat harder steel in shipbuilding, but the milder character used for boilers; and if they punched a line of holes across a plate of this steel and subjected it to tensile strain, the total strain that a piece of metal would bear should be fully equal to the normal strength of that material multiplied in the remaining cross section, and he based that view, not upon a mere theoretical ground, but upon many experiments which he had seen made and tried. Mr. Pearce told them that the punching did not affect the strength of the material in mild steel. That was the material for boilers. That was contrary to all their experience, and they had been in the habit of making tests with the plates for all the boilers that they made. Then, as to the question of annealing, that also was contrary to all their experience, for they found if they did not anneal a plate, after having worked a portion of that plate, there was a liability to crack. In his experience in steel, which had extended over a great many years, he had upwards of a thousand plates cracked through the inadvertence of not annealing. In his opinion, in future, all boilers made of steel should be bored and not punched. The boilers that he was making now were all bored, and, in fact, he was sure that the whole of the steel boilers that his firm had made since the *Livadia's* failure had been bored. The failure on the part of the steel of the *Livadia's* boiler had not shaken any confidence in him a bit. He thought that in looking back to the number of failures in other materials, certainly for every plate of steel that had failed there had been twenty plates of iron. He thought that the larger manufacture of the ingot was made with metal not of the same quality, and that it was more likely to contain inferior as well as superior metal, and, not being properly worked, it would not amalgamate fairly.

In reply, Mr. John regretted that no representative of the makers of the steel plates which had failed was present. The plate which gave way at Mr. Denny's was Siemens-Martin steel; for he himself had heard Mr. Snelus say that for ten years he had made Bessemer plates without a failure, and the moment he began to make Siemens steel he got into a mess. Tests should be on rough, not on planed, plates. There was a great deal about steel yet to be learned. For example, although it was said that the *Livadia's* plates were bad because they were not worked enough, it was difficult to maintain that, in face of the fact that the little test ingot taken from the Bessemer ladle, the "baby" ingot gave admirable metal.

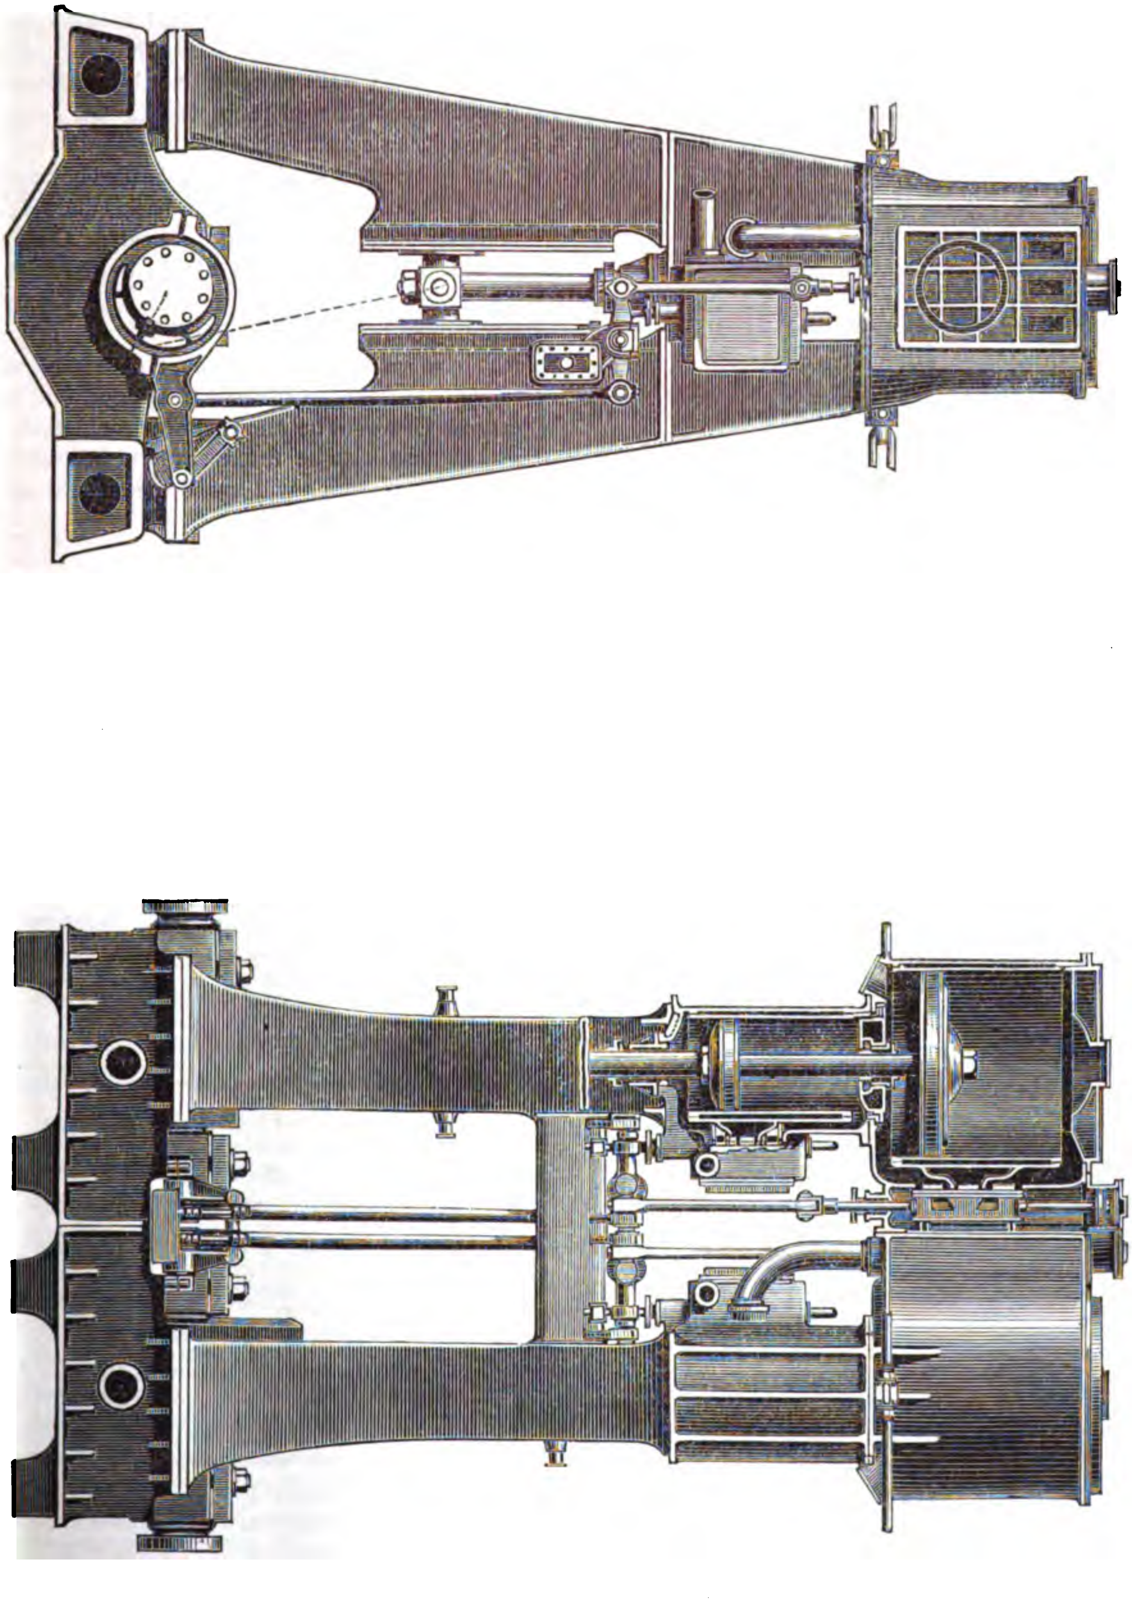
A vote of thanks was passed unanimously to Mr. Parker.

YOUNG'S COMPOUND MARINE ENGINE.

THIS design of a compound engine is a very neat one indeed, the side brackets or wings being so managed that they serve as a support to both high and low pressure cylinders, giving both in appearance and reality a great solidity to the engine. This is all the more important in the form of engine used, as the low pressure cylinder is above the smaller high pressure one, which would otherwise have caused the engine to look top-heavy, and in practice to be liable to a considerable degree of vibration. It will be seen from the sectional view that both cylinders are brought together end to end with only a single cover and stuffing box between. The advantages of this form of junction between the cylinders is obvious, in that it saves space, prevents radiation in some degree, and entirely obviates the drawing in of air through a gland into the low pressure cylinder when a vacuum is created. We are of opinion that this air leakage into the vacuum of the low pressure cylinder has a good deal to do with the imperfect vacuums so often obtained.

The chief practical difficulty, however, to such an arrangement, lies in the difficulty of getting at the intermediate cover and stuffing box between the two cylinders. This is fairly well attained in Mr. Young's engine, by the use of a man-hole in the projecting lower face of the low pressure cylinder. Through this the joint of the intermediate cover may be broken without taking off the low pressure piston, and in the same way the gland can be repacked. This gland may be screwed up as desired after packing by means of a worm wheel, from the outside of which the details are very clearly shown.

By breaking the joint of the two covers, both pistons may be drawn out still attached to the rod. This is a great point, as it is most desirable not to break the piston joint on the rod for temporary repairs. Nor is there any necessity to drain most of the cylinders, which is the case in some tandem engines, where an intermediate distance piece is used, or where the high pressure cylinder is on the top of the low.



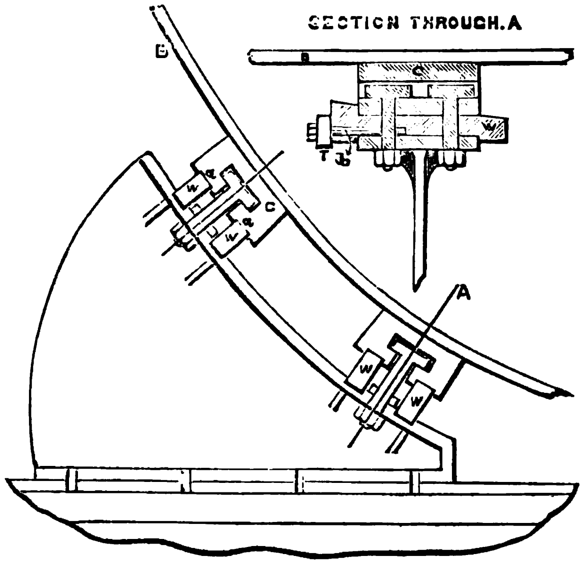
YOUNG'S COMPOUND MARINE ENGINE.

The valve gear, shown as adapted to the engines in our illustration, is that known as Marshall's gear, but although this gear works in very simply, it is by no means essential, and any usual form would work in just as well.

The very small size of the pressure slide valve may be noted as a good point, since it will relieve frictional resistance. The whole engine works out very lightly and compactly, containing great strength and power in a small space. The design is patented by the inventor, Mr. Henry S. Young, of 34, London Wall, E.C.

WHYTE'S REMOVEABLE BOILER BEARERS.

ANYTHING that will serve to prevent the deterioration of boiler shells, or to render such deterioration more readily observable will prove of great value to the users of steam boilers, either afloat or ashore. It is well known that the position of perhaps greatest deterioration or fitting is on the bearers or supports of the boiler. When these are fixtures, as they always are, as at present used, the corrosion has every opportunity to go on quietly and persistently. It is impossible to ascertain what injury is going forward, and it is equally impossible to scrape, clean, or paint that portion where it rests on the supports.



Mr. John Whyte, who is a practical sea-going engineer on board the Imperial Chinese gun-boat *Sin-tsing*, has invented the accompanying removable bearer, which to our minds will prove a great boon for the fixing of boilers afloat.

Referring to the illustration, B represents the boiler plate, C, a bearer or clock, with a T shot running through it, and into which two T headed bolts are placed. The boiler is supported on the two wedges W which are prevented from falling out by the guard piate I when the large end of the wedges are placed downwards. The bolt A has an eye on the inside end through which one of the T headed bolts passes ; a nut being screwed up on the outside of the plate preventing any possibility of the wedges slackening back.

It is obvious that when the T headed bolts are slacked back the wedges may be driven back, the weight being taken by other bearers, and the bearers C may be removed in succession and replaced in a very short time. The boiler shell may in such case be examined and scraped, and painted as desired. Any corrosion which may have set in would be seen at once, and as it generally arises from the accumulation or drip of water, the cause itself would be removed on examination. These bearers may also be fitted and finished before being sent on board, which will save some amount of chipping and fitting when in place.

ON THE EXPERIMENTS WITH THE PERKINS MACHINERY OF THE STEAM YACHT "ANTHRACITE."

From the Journal of the Franklin Institute.

By Chief-Engineer ISHERWOOD, United States Navy.

(*Continued from page* 7.)

TABLE CONTAINING THE DATA AND RESULTS OF THE EXPERIMENT MADE AT THE NEW YORK NAVY YARD ON THE MACHINERY OF THE STEAM YACHT "ANTHRACITE" BY A BOARD OF UNITED STATES NAVAL ENGINEERS—*Continued.*

HORSES-POWER.	Indicated horses-power developed in the 1st cylinder	20·4308
	Indicated horses-power developed in the 2nd cylinder	7·8290
	Indicated horses-power developed in the 3rd cylinder	39·4483
	Aggregate indicated horses-power developed in all the three cylinders	67·7081
	Net horses-power developed in the 1st cylinder	20·0628
	Net horses-power developed in the 2nd cylinder	6·3430
	Net horses-power developed in the 3rd cylinder	33·1150
	Aggregate net horses-power developed in all the three cylinders	59·5208
	Total horses-power developed in the 1st cylinder	28·8902
	Total horses-power developed in the 2nd cylinder	23·2490
	Total horses-power developed in the 3rd cylinder	28·0133
	Aggregate total horses-power developed in all three cylinders	80·1525
	Total horses-power developed by the expanded steam alone in the 1st cylinder ...	10·7400
	Total horses-power developed by the expanded steam alone in the 2nd cylinder ...	23·2490
	Total horses-power developed by the expanded steam alone in the 3rd cylinder ...	28·0133

Weight of Steam accounted for by the Indicator.	Pounds of steam present per hour in the 1st cylinder at the point of cutting off the steam, calculated from the pressure there... ...	633·5094
	Pounds of steam present per hour in the 1st cylinder at the end of the stroke of its piston, calculated from the pressure there...	609·6268
	Pounds of steam condensed per hour in the 1st cylinder to furnish the heat transmuted into the total horses-power developed in that cylinder by the expanded steam alone	30·8817
	Sum of the two immediately preceding quantities	640·5085
	Pounds of steam present per hour in the 2nd cylinder at the end of the stroke of its piston, calculated for the pressure there ...	808·3992
	Pounds of steam condensed per hour in the 1st and 2nd cylinders to furnish the heat transmuted into the total horses-power developed in those cylinders by the expanded steam alone	93·9542
	Sum of the two immediately preceding quantities	902·3534
	Pounds of steam present per hour in the 3rd cylinder at the end of the stroke of its piston, calculated for the pressure there ...	1150·7924
	Pounds of steam condensed per hour in the 1st, 2nd and 3rd cylinders to furnish the heat transmuted into the total horses-power developed in those cylinders by the expanded steam alone	167·0720
	Sum of the two immediately preceding quantities	1317·8644
Economic Results.	Pounds of coal consumed per hour per indicated horse-power	2·7115
	Pounds of coal consumed per hour per net horse-power	3·0844
	Pounds of coal consumed per hour per total horse-power	2·3319
	Pounds of combustible consumed per hour per indicated horse-power	2·2333
	Pounds of combustible consumed per hour per net horse-power	2·5405
	Pounds of combustible consumed per hour per total horse-power	1·9207
	Pounds of feed water consumed per hour per indicated horse-power	21·6387
	Pounds of feed water consumed per hour per net horse-power	24·6152
	Pounds of feed water consumed per hour per total horse-power	18·2791
	Fahrenheit units of heat consumed per hour per indicated horse-power	24265·69
	Fahrenheit units of heat consumed per hour per net horse-power	27603·52
	Fahrenheit units of heat consumed per hour per total horse-power	20498·22

(*To be continued.*)

[Owing to want of space we are compelled to let the remainder of this article stand over till next month.—Ed. M.E.]

The Phosphor Bronze Company, Limited, of Sumner Street, Southwark, London, S.E., have been awarded the highest prize, and also a Silver Medal for their exhibits of Phosphor Bronze specimens at the Melbourne Exhibition.

The trial of the improved Whitehead torpedo has been "productive of much success," and on the strength of this it has been decided to purchase four more for the Torpedo School, but the projectile is to be constructed of phosphor bronze, instead of steel.

The Admiralty overseeer at Sheffield reports that he is of opinion that the heat at which it is most dangerous to work steel is about 540 deg. Fah., and that the dangerous heat ranges over about 150 deg., viz., from 430 deg. to 580 deg. Fah., when it varies in colour from a light straw to a dark blue. He also considers that although the danger may not be so great throughout the whole of this range as it is at the first-named temperature, it is still, in his opinion, extremely unsafe to put any work whatever upon mild steel within these limits.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of the* Marine Engineer *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—Ed.]

LAUNCHES.—English.

Poh Ann.—On March 29th Messrs. Wigham Richardson & Co., launched from the Neptune Shipyard, Low Walker, a steamer named the *Poh Ann*, being the second built by them to the order of Messrs. Guthrie & Co., of Singapore and London, for service in eastern seas. She will be engined by the builders, and although designed for fast passenger traffic, will carry a large cargo on an exceedingly small consumption of fuel. All the recent improvements in hull and machinery have been introduced into the vessel, and she fulfils every requirement of the Board of Trade and Lloyd's.

Royal Norman.—On March 30th there was launched from the yard of Mr. J. T. Eltringham, Stone Quay, South Shields, an iron tug steamer named the *Royal Norman*, of the following dimensions; —108 by 18·6 by 10 ft. She has been built to the order of Mr. J. M. Rennoldson, Engineer, &c., South Shields, for Messrs. Sharp Bros., of Sunderland and Cardiff. She will be fitted with engines of 80-horse power nominal, feathering wheels, steam windlass, &c., and all the latest improvements of the Board of Trade, under whose survey she has been built.

Aristides.—On March 31st Messrs. T. Royden & Sons, launched from their yard on the Mersey a steamer built of steel. Her carrying capacity will be 2,300 tons. As the vessel left the ways she was christened the *Aristides* by Miss Johnson. The steamer has been built to the order of Messrs. Layborn & Legge, Steamship Owners, of Liverpool, and will be fitted with engines on the compound surface-condensing principle, 700 indicated horse power, by Messrs. J. Jack & Co., and other approved modern appliances for economy and dispatch. Harfield's windlass, Harrison's steam steering gear, and Messrs. Cooke's & Mylchreest's patent split boss propeller, by which great economy in overhauling will be affected, have also been supplied, and the consequent loss and delay attending such work avoided. The vessel will receive the highest class at Lloyd's. She will be commanded by Captain De Silva. The steel for the vessel has been supplied by Messrs. W. S. & N. Caine, from the Landore Works, made by the Siemens-Martin process.

Akaba.—On March 31st Messrs. M. Pearse & Co., launched from their iron shipbuilding-yard at Stockton-on-Tees, an iron screw steamer of the following dimensions:—Length between perpendiculars, 300 ft.; extreme breadth, 36 ft.; depth of hold to top of floors, 25 ft. 6 in. This vessel is about 2,300 tons gross register, and will carry about 3,300 tons dead weight. She is built of the highest class granted at Lloyd's. She has a full poop aft, in which is fitted a saloon with passengers and officers' accommodation. This vessel is built off the three-decked rule, with two decks laid, both being of iron. She will be rigged as a three-masted schooner, and will carry double topsails on her foremast. She will be provided with engines on the direct-acting surface-condensing principal of 280-horse power nominal, by Messrs. Blair & Co., of Stockton, four steam winches and patent steam steering gear. She has double bottom for water-ballast, and all the most recent and improved appliances for expeditiously loading and discharging cargoes, and for ventilation and other sanitary purposes. This is the fourth vessel Messrs. M. Pearse and Co. have built for her Owners. As she left the ways she received the name of *Akaba.*

Juliet.—On March 31st Messrs. Raylton Dixon & Co. launched from the Cleveland Dockyard an iron steamer named the *Juliet*, built to the order of Messrs. C. T. Bowring & Co., of Liverpool, to be employed in the Red Cross Line of steamers trading from the Tyne to New York. She is very similar in dimensions to the *Titania* (s), which was built by them for the same firm about twelve months ago, being 285 ft. long, 36 ft. beam, and 24 ft. 6 in. depth of hold. Her cross tonnage is 2.070, and she will carry about 2,840 tons deadweight. As these vessels are largely employed in the important cattle trade which is springing up between New York and the Tyne, she has been specially fitted with an iron shelter deck, instead of the unsightly wooden erections which are generally employed for the purpose in this class of steamers, and has besides every convenience for carrying cattle, and also for the rapid loading and discharging of grain cargoes. She will be fitted with engines of 180-horse power by Messrs. T. Richardson & Sons, of Hartlepool, and will be ready for sea in a short space of time. On leaving the ways she was christened the *Juliet*, by Mrs. Olsen, wife of the manager of the yard. Only one month elapsed from the date of order to this vessel being entirely in frame.

Kelat.—On March 31st an iron sailing ship was launched from the building-yard of Messrs. Richardson, Duck & Co., South Stockton-on-Tees, of the following dimensions, viz. :—Length over all, 273 ft. 2 in.; length b.p., 255 ft.; breath, extreme, 41 ft.; depth in hold, 23 ft. 9 in.; tonnage, gross, about 1,875 tons; tonnage, nett, 1,800 tons. She is classed 100 A1 at Lloyd's, and has been built under special survey. The vessel has a full poop for the accommodation of first-class passengers, the captain, and officers; a topgallant forecastle for the crew; and a deck-house amidships for the petty officers, galley, &c. The ship has been built to the order of Thomas Bates & Sons, Liverpool. As the vessel was leaving the ways she was christened the *Kelat* by Mrs. Dixon, wife of Dr. Dixon, of Stockton-on-Tees.

Napier.—On March 30th there was launched from the yard of the Tyne Iron Shipbuilding Company, Willington-on-Tyne, a steamer for Mr. James Tait, Newcastle-on-Tyne. The following are her dimensions :—Length. 280 ft.; breadth, 36 ft.; depth, ;22½ ft. to top of water ballast tank; and 25½ ft. to bottom of water ballast tank; equal to about 24 feet depth ordinary build. She has a cellular double bottom. The vessel was built under special survey, and is classed 100 A 1 at Lloyd's. She is intended for the Indian and American trades, and specially adapted for a Government store ship. She will carry about 2.850 tons deadweight. The engines, which will be 180-h.p. nominal, are to be fitted in by the North-Eastern Engineering Company, Sunderland. The vessel was christened the *Napier* by Miss Isabella Wait, daughter of the owner.

Brenda.—On March 30th an iron screw steamer, built to the order of Mr. F. Erskind, of West Hartpool, was launched from Messrs. E. Withy & Co's shipyard at Hartlepool. Her dimensions are :—Length between perpendiculars, 257 ft. 6 in.; beam, 34 ft. 6 in.; depth of hold to Lloyd's floors, 19 ft. 6 in. She is classed 100 A 1 at Lloyd's, and will be fitted with engines of 150-horse power, by Messrs. Richardson & Sons, Middleton. She is built to carry 2,325 tons, and a special feature in the ship is that all decks, skylights, companion, &c., are constructed of iron. The vessel, which will be engaged in the Atlantic and Mediterranean Trades, is numbered 95 in the builders' books. As she left the ways she was christened the *Brenda*, by Mrs. Jabez Wood, of Hartlepool.

Strabo.—On April 2nd, this steamer, of 1,900 tons gross register, was launched at the yard of the Barrow Shipbuilding Company. She is meant for Oriental traffic. She is 290 ft. between perpendiculars, 35 ft. beam, depth of hold 24 ft. The engines are direct and compound, the cylinders being 26 and 60 ins. respectively; indicated horse-power 1,000. She is brigantine rig, and is owned by Messrs. Lamport & Holt, of Liverpool.

Merannio.—On April 2nd, Messrs. Wm. Grey & Co., West Hartlepool, launched from the shipbuilding-yard an iron screw steamer, measuring 216 ft. in length, 31 ft. breadth of beam, and 15 ft. 2 ins. depth of hold, intended for the Baltic and Mediterranean trades. The vessel is to be engined by Messrs. Blair & Co. (Limited), of Stockton, of 100-horse power, and is to be fitted with every modern improvement. This steamer, which is expected to carry over 1,200 tons deadweight, will be under the management of Messrs. Gledhill & Dishart, Leith. On leaving the ways she was named *Merannio*, by Miss Florence Gertrude Hunter, of Pendleton, Manchester.

Grangefell.—On April 2nd there was launched from the shipyard of Messrs. R. & J. Evans & Co., Liverpool, an iron screw steamer for the firm of Messrs. Hume, Smith, & Co., Liverpool. On leaving the ways she was christened the *Grangefell*, by Mrs. Smith. The steamer is intended for the conveyance of iron ore coastwise and pig iron and rails in transit, and is provided with all the most recent appliances and arrangements for the ready discharging and working of heavy cargoes. Messrs. David Rollo & Son, of Fulton Engine Works, are supplying the machinery; the engines are compound surface-condensing, and are constructed so as to economize fuel.

Perseverauce.—On April 2nd, Messrs. Short Bros launched at Pallion, Sunderland, the steamer *Perseverance*, built to the order of Messrs. Freear & Dix, Sunderland, who intend her for trading purposes in the Baltic, White Sea, and Lower Mediterranean. Her length over all is 225 ft., between perpendiculars, 220 ft.; extreme breadth, 32 ft. 6 in.; and depth of hold, 16 ft. Her gross register tonnage is 1,100, and deadweight cargo capacity about 1,450 tons. Half-poop to bridge, with full topgallant forecastle. Her classification is the highest in Liverpool Registry, and she is fitted with engines of 110-horse power by Mr. John Dickinson, of Palmer's Hill Engine Works. She has three large hatches, with horizontal steam winches to each, by Mr. Crawford, of Bonner's Field, and also patent steering gear, Harfield's patent windlasses, and all the latest improvements connected with merchant Shipping. She was christened by Mrs. Dix.

Baron Ardrossan.—On April 14 a vessel was launched from the Whitehall Iron Shipbuilding-yard, Whitby, of which Messrs. Turnbull & Son are the proprietors. The vessel, which was christened *Baron Ardrossan* by Miss Hogarth, daughter of the owner, is of the following dimensions :—Length, 243 ft. 6 in.; breadth, 34 ft.; depth of hold, 17 ft. 9 in.; engines, 130-horse power, by Blair & Co., of Stockton, and patent windlass by Emerson, Walker & Co., London. The deadweight carrying capacity is about 1,750 tons. The vessel has been built to the order of Mr. Hugh Hogarth, Ardrossan.

Arica.—On April 14th a screw steamer, built to the order of the Pacific Steam Navigation Company, and intended to be employed in their West Coast Service, was launched from Messrs. Laird Brothers' works at Birkenhead, and was christened the *Arica* by Miss Nelson, daughter of Mr. P. Nelson, one of the directors of the company. The *Arica* is constructed entirely of Siemens-Martin steel, and is of the following dimensions :—Length, 300 ft.; beam, 36 ft.; depth to main deck, 22 ft.; tonnage, builders' measurement, 1,920 tons. She will be fitted with a set of direct acting inverted compound engines to work at 90 lbs. pressure, and develop 1,100 indicated horse power, which, with their boilers (also of steel), are of Messrs. Lairds' manufacture, and ready to go on board. The *Arica*, like the majority of the company's coast steamers, is constructed with an awning deck, and in houses on that deck there will be accommodation for a moderate number of passengers, as also for captain and officers, but she has been designed principally for cargo and cattle traffic. She will be rigged as a schooner with three steel pole masts, and fitted with steam steering gear and all the latest improvements. The *Arica* is the fifth vessel launched by Messrs. Laird within four months, and she will shortly be followed by the *Ecuador*, a sister ship, for the same company.

Surrey.—On April 16th Messrs. W. Gray & Co., of West Hartlepool, launched from their yard a screw steamer of the following dimensions :—Length, 360 ft.; breadth, 40 ft.; and depth, 24 ft. 6in., and 31 ft. 3 in. to spar deck. The vessel has been built to the order of the Atlantic Transport Company (Limited), and will be under the management of Messrs. Hooper & Williams, London. She is intended for the cattle trade between London and Boston. Special attention has been given to ventilation. The cattle fittings are all permanent, and made entirely of iron, and are for 550 cattle and 1,000 sheep. The new steamer is to be engined by Messrs. Blair & Co. (Limited), Stockton, 220-horse power, and furnished with every modern appliance and improvement, and she will carry 3,800 tons deadweight; to be commanded by Captain Bacon On leaving the ways the vessel was christened the *Surrey* by Mrs. John Hooper, wife of the managing owner.

Kingsley.—On April 16th Messrs. Thomas and William Smith launched from their yard at North Shields a screw steamer, built to the order of Messrs. Edward Eccles & Co. of Newcastle. This vessel (which was named the *Kingsley*) is 180 ft. long, 30 ft. beam, and 13 ft. 6 in. deep from top floors. She has been built under special survey for class 100 A 1 at Lloyd's. Her carrying capacity is about 800 tons. She is destined principally for the coal trade to small coasting ports.

Sportsman.—On April 16th a screw steamer, built to the order of Mr. Wm. J. Jobling, Newcastle, was launched from Messrs. Palmer & Co.'s yard at Jarrow. The vessel measures 290 ft. over all, her beam is 36 ft., and her depth is 23 ft. Her carrying capacity deadweight will be 3,000 tons. Her engines, which will be built at Jarrow, will be of 200-horse power nominal. She will class 100 A 2 at Lloyd's. She is intended for the Indian and Atlantic trades. She was christened the *Sportsman*.

Crawshaw Bailey.—On April 25th Messrs. Edward Finch & Co. (Limited), of Chepstow, launched from their yard an iron screw steamer, built to the order of Captain E. J. Harley, Milton Villa, Penarth. Her dimensions are :—Length, 110 ft.; breadth, 19 ft.; depth of hold, 10 ft. 2 in.; classed 100 A 1 at Lloyd's, to carry 230 tons deadweight. She has full poop, bridge, topgallant forecastle, and is fitted with steam winch, patent windlass, &c.; engines compound, surface condensing, inverted, vertical direct-acting, of 45 nominal horse-power, to work at a boiler pressure of 85 lbs. per square inch. As she left the ways she was christened the *Crawshaw Bailey* by Miss Harley. There were also present Captain and Mrs. Harley. Mr. Aisbitt (designer of the ship), Mount Stuart Square, Cardiff, and Miss Aisbitt. The builders were represented by Mr. Rowe, the managing director of the Company.

Barnsley.—On April 27th there was successfully launched from the shipbuilding-yard of Messrs. Robert Thompson & Sons, Southwick, an iron screw steamer, built to the order of Messrs. Henry Briggs, Son & Co., Hull, of the following dimensions, viz. 284 ft. long by 35 ft. broad and 24¼ ft. depth of hold, having been constructed on the three deck rule, under Lloyd's special survey, to class 100 A 1 She has a short full poop with cabin for captain, and spare berths; accommodation in bridge-house amidships for officers and engineers, and for firemen and crew in top-gallant forecastle, and is being fitted throughout with all the latest improvements, including ample water ballast fore and aft, four steam winches, and donkey boiler by Messrs. Roger & Co.; crane on forecastle for lifting anchors, &c.; patent steam steering apparatus amidships; also patent screw gear aft, Harfield's patent windlass, &c., &c. Her engines, which are on the inverted direct-acting compound surface condensing principle, and of 200-horse power, are by George Clark, Esq., Southwick. As the vessel left the ways she was gracefully christened the *Barnsley* by Miss Reed, of Hull.

LAUNCHES.—SCOTCH.

Oaks.—On March 30th, Messrs. Thomas B. Seath & Co. launched from their shipbuilding-yard at Rutherglen a steam yacht of 132 tons burthen, specially built for the use of Mr. T B. Seath, and designed with a view to the attainment of great speed. Her dimensions are as follows:—Length, 140 ft.; breadth of beam, 14 ft.; depth, 8½ ft. She is fitted with engines of 14 and 20 inch cylinders, which will work at a pressure of 100 lbs. steam. On leaving the ways she was named the *Oaks* by Miss Jessie Steel, daughter of Provost Steel, Ayr.

Lido.—On March 31st Messrs. Murdoch & Murray, Port Glasgow, launched the *Lido*, a steel screw steamer about 1,200 tons register, with cellular double-bottom water-ballast fore and aft, and classed 100 A 1 at Lloyd's. She has been built for Messrs. Raeburn & Verel, Glasgow, under the superintendence of Messrs. M'Nicoll & Smith, Glasgow, and will be fitted with engines of 120-horse power nominal, by Messrs. Kincaid, Donald & Co., Greenock.

Imerina.—On April 1st the Campbeltown Shipbuilding Company launched from their building.yard, at Trench Point, a screw steamer of 350 tons burthen, the dimensions of which are 135 ft. by 21 ft. 3 in. by 10 ft. 9 in. She has been built to the highest class of Lloyd's, under special survey, and will take her station in the East, where she will carry deadweight cargo and cattle, accommodation being also made for passengers. As the vessel left the ways she was named the *Imerina* by Miss Alice M'Fadyen, of Messrs. Kincaid, Donald & Co., of Greenock, with compound surface condensing engines, and will be fitted with all the latest improvements.

Falcon.—On April 1st Messrs. Dobson & Charles launched from their yard, at Grangemouth, an iron screw yacht of 60 tons, to the order of Messrs. John Englis & Co., naval architects, Glasgow. Dimensions:—82 ft. by 12 ft. by 8 ft. The engines are compound surface-condensing of 100-horse power effective, by Messrs. Scott Brothers, Crookston Street, Glasgow. The yacht was named *Falcon* as she left the ways.

Elbe.—On April 2nd Messrs. John Elder & Co. launched from their shipbuilding yard at Fairfield, Glasgow, a fine iron screw steamer, named the *Elbe*, for the North German Lloyd's Company of Bremen—the first vessel yet built at Fairfield for the large fleet of that eminent company. This steamer, which is intended for the Bremen and New York trade, is of the following dimensions:—Length, 440 ft.; breadth, 45 ft.; depth, 36 ft. 6 in. She is classed in the highest grade of the Bureau Veritas, with several extras over the requirements of that registry, such as iron lower and orlop decks, and additional water-tight bulkheads. Teak is employed for the upper deck, while the deck-houses and deckwork are partly formed of teak and partly of iron. In order to protect the vessel from the heavy Atlantic seas, strongly constructed iron turtle-back decks are placed at both ends of the ship. Occupying the central part of the upper deck there are the houses for the officers, firemen, &c., together with the galleys, smoking rooms, and entrances to the first and second saloons, &c.; and extending over the whole length of these deck-houses there is a most spacious promenade deck, about 180 ft. long and the whole width of the vessel, and entirely reserved for the use of the first-class passengers. In addition to the accommodation for the ship's officers and crew—numbering 170—the *Elbe* will carry 120 first-class, 120 second-class, and 1,000 steerage passengers. The first and second saloon passengers will be berthed on the main deck, and the steerage passengers on the lower deck. The chief saloon, which is placed forward of the engines and boilers, will be a very handsome and comfortable apartment, being about 40 ft. square, beautifully lighted from a cupola from the promenade deck, and furnished and fitted up in the most luxurious manner. The sleeping cabins for the first-class passengers are situated before and abaft the saloon, while the smoking-room is on the upper deck and the ladies' saloon on the promenade deck. The accommodation for the second-class passengers is placed abaft the first-class, and will be fitted up in a plain though comfortable manner. Rigged with four pole masts of iron, and with yards on the fore and main masts, the *Elbe* will be provided with steam windlass, steam and hand steering gear, steam winches, steam hold pumps, steam "Navy" pumps, fresh-water condenser, and, in fact, all modern appliances to insure the safety of the vessel at sea, and to facilitate the working of cargo. She will be propelled by compound engines of the inverted cylinder type supplied by the builders, having two low-pressure cylinders of 85 in. diameter, and one high-pressure cylinder of 60 in. diameter, by 5 ft. stroke, and working up to 75 ℔. pressure. Steam is to be supplied by four double-ended boilers, with six furnaces in each; and it is fully expected that the engines will develop 5,400 indicated horse power. As the vessel left the ways she was named the *Elbe* by Miss Cargill.

Innishowen.—On April 4th there was launched from the building yard of Messrs. Napier, Shanks & Bell, Yoker, a paddle-steamer of about 110 tons, for Messrs. M'Crea & M'Farlane, of Belfast and Londonderry, intended for passenger and goods traffic on Lough Swilly. The Innishowen, as the new steamer is named, while designed to develop the increasing trade of the district, will be specially fitted for the accommodation of passengers. The The vessel was named by Miss Duncan, Hillhead. The machinery is being fitted on board by Messrs. Ross & Duncan, Glasgow, and the steamer is expected to be placed on her station next month.

May.—On April 4th, Messrs. Robert Steele & Co., Shipbuilders, Cartsdyke, Greenock, launched from their yard a 40-ton racing cutter, which was named the *May*. Her dimensions are:—Length of load-line, 63 ft. 7 in.; and breadth, 12 ft. The cutter is composite, with steel frame, teak topsides, and elm bottom, copper and metal fastened throughout. She will have the highest class at Lloyd's.

Horsa.—On April 6th Messrs. Lobnitz & Co. launched from their yard at Renfrew an iron screw steamer 205 ft. by 27 feet by 21 feet, and immediately thereafter placed her in their tidal docks to receive her boilers and machinery. This vessel has been built to the order of Jydsk Engelske Dampskibs Selskab of Aarhuus, and has been specially designed for the cattle trade between Aarhuus and Newcastle. She has water ballast fitted in main hold, and in double bottom in the after hold, as well as tank compartments in the peaks of the vessel. The boilers and machinery which the same builders have constructed for this vessel are 165-horse power nominal, and will enable the vessel to maintain an easy service speed of 11 knots per hour. She will be commanded by Captain Bense. The ceremony of naming the vessel *Horsa* was performed by Mrs. John Jack, wife of one of the partners of the builders' firm.

Serena.—On April 11th there was launched from the shipbuilding-yard of Messrs. Robert Napier & Sons, Glasgow, a steel screw steamer of 3,000 tons, for the Pacific Steam Navigation Company, Liverpool. This is the fourth vessel of this type built for the company by Messrs. Napier. She is designed for the Pacific trade, and fitted with the most modern appliances for the accommodation of passengers and the efficient working of the cargo, a new feature in the vessel being the hydraulic winches and windlass, which have been fitted on board. As the vessel left the ways, she was named the *Serena* by Miss Hardy, and was afterwards towed to the harbour, where she will receive her engines, of 2,500 indicated horse-power, which have been constructed by the builders.

Catania.—On April 13th Messrs. Alex. Stephen & Sons, launched from their building yard at Linthouse, Glasgow, an iron screw-steamer, of about 2,300 tons, built under special survey to the highest class in Lloyd's. This is the latest addition to the fleet of Messrs. Rob. M. Sloman & Co., Hamburg, and is the eleventh vessel built by the Messrs. Stephen for that firm. She is of the most modern type, embracing all recent improvements, such as a double bottom throughout for water ballast on bracket principle, Emerson Walker & Co.'s, patent windlass, steam steering gear, steam winches, and all the best appliances for working cargo, &c. The accommodation for captain and officers is in houses amidships, and, in connection with same, there is accommodation for a limited number of first-class passengers. The engines and boilers, also made by the Messers. Stephen, were fitted on board before launching. The cylinders are 35 in. and 65 in. diameter by 42 in. stroke, supplied with steam from two very ample boilers, suitable for 80 lbs. pressure. The ship, which has a full poop and topgallant forecastle, is rigged as a two-masted schooner. She was named the *Catanea* by Miss Lucy Aikman, Middlefield, Glasgow. One of the specialties in the vessel is a hold for carrying meat, refrigerated by an apparatus supplied by Messrs. M'Ilwraith, M'Eacharn & Co., London.

North Sea.—On April 13th there was launched at Dundee, by Messrs. Alex, Stephen & Sons, a screw steamer, named the *North Sea*, built to the order of the Dundee, Perth, & London Shipping Company. Her dimensions are as follows:—Length, 230 ft.; breadth, 30½ ft.; and depth of hold, 17 ft. 2 in. She is 1,100 tons gross, and will be fitted up by Pearce Bros., Dundee, with engines 120-horse power. The *North Sea* is a cargo boat, intended for the Baltic and White Sea Trades, and will be commanded by Captain Booth, formerly of the Scotia (s).

Routenburn.—On April 14th Messrs. R. Steele & Co. Greenock, launched from their yard a four-masted iron sailing ship of about 2,000 tons register, built to the order of Messrs. D. & R. Shankland, Greenock. She is 305 ft. in length over all; length of keel and forerake, 274 ft.; breadth 42 ft.; and depth of hold, 24 ft. The vessel has been built to the highest class in Lloyd's, and the latest improvements have been taken advantage of in her construction. The large vessel, as she left the ways, was named the *Routenburn* by Miss Bessie Shankland, daughter of one of the owners. The *Routenburn* is barque-rigged with jiggermast, and is to be employed in the East Indian trade. After the launch, she was towed into the Victoria Harbour, where she will be fitted out. Her maiden voyage will be to Calcutta.

Amitié.—On April 14th Messrs. H. M'Intyre & Co., launched from their shipbuilding-yard at Merksworth, Paisley, an iron screw steamer of 850 tons. The vessel, which was named the *Amitié*, has been built to the order of a French firm for their trade between France and Britain. She is built to the highest class at Lloyd's, under the superintendence of Captain Courpon, who is to command her; is fitted with water ballast in double bottom, all fore and aft, and all usual appliances for loading and discharging quickly. She will be fitted with a pair of compound-surface condensing engines by Messrs. Fleming & Ferguson, Phœnix Engine Works, Paisley.

Armenia.—On April 14th a screw steamer was launched from the shipbuilding-yard of Messrs. David and William Henderson, at Meadowside, on the Clyde. Her dimensions are 364 ft. in length, 38 feet in breath, and 28 ft. 6 in. in depth, her gross tonnage being 3,380. She will be fitted with compound engines, with cylinders of 33 and 66 in. diameter, and 5 ft. stroke. This vessel is a sister ship to the *Hispania* and *Roumania*, lately built in the same yard. She is fitted with Emerson, Walker & Co.'s Patent Direct Steam Capstan Windlass, and is intended for the Anchor Line service between Glasgow, Liverpool, and Kurrachee. As she passed from the stocks into the water the new vessel was named the *Armenia*.

Laja.—On April 16th Messrs. John Reid & Co. launched from their yard at Port Glasgow a steamer named the *Laja*, of the following dimensions:—Length, 320 ft.; breath of beam, 40 ft.; depth of hold, 23 ft.; and of 2,200 tons. The *Laja*, which has four decks, has been built for the South American Company of Steamers, Valparaiso, and is to trade on the West Coast of South America. There is accommodation on board for 100 first-class passengers. This vessel is fitted with Harrison's patent steam steering gear. Messrs. Rankin & Blackmore, Greenock, are to supply the engines, of 400-horse power, and after the launch the steamer was towed to Greenock.

LAUNCH—IRISH.

Mary Miller.—On April 14th a new three-masted schooner was launched from Mr. Rodger's shipyard, Carrickfergus. Her dimensions are:—Length 96 ft.; breadth of beam, 22 ft.; depth of hold, 9 ft. 8 in. Her register tonnage will be about 100, and her carrying capacity 210 tons. The ceremony of christening the new vessel was performed by Mrs. Lynn, who named her the *Mary Miller*. She has been built to the order of Messrs. James Fisher & Sons, of Barrow, and is a sister ship to the *Fanny Crossfield*, built some time ago by the same firm. She has been classed A 1 at Lloyd's for 12 years, and is intended for the iron ore trade.

TRIAL TRIPS

Romeo.—On March 31st the new mail steamer *Romeo*, the latest addition to the fleet of steamers belonging to Messrs. T. Wilson, Sons, & Co., of Hull, performed her trial trip, and the test which she underwent proved satisfactory in every respect. This vessel is specially constructed for carrying mails and passengers, and is adapted to convey 1,000 emigrants between decks, 20 second class passengers, and 40 saloon passengers. She is 275 ft. in length, 34½ ft. broad, and 20 ft. deep, her registered tonnage being 1,209, and gross tonnage 1,850. The engines are 300 nominal horse power combined surface condensing, the cylinders being 38 in. and 76 in. diameter respectively, by 48 in. stroke, and are supplied by steam of 80 lbs. pressure. The steam is generated in two double-ended cylindrical boilers of very large size, having six furnaces 42 in. each in diameter. They are manufactured of Siemens-Martin steel, supplied by the Steel Company of Scotland, and the size will admit the full power being maintained throughout the voyage. The engines are fitted with the latest improvements, and are controlled by powerful steam steering gear, which is arranged to propel the engines when the steamer is in port, and the machinery undergoing repairs. During the trip the engines ran at 62 revolutions (full boiler pressure of 80 lbs.) the vacuum being 27 in. and the indicated horse power 1,600. This speed was maintained all the way to the measured mile, along which a mean speed of 13 knots for four journeys—two each way—was obtained. The time taken in turning a complete circle was 5 minutes 30 seconds. Notwithstanding that the engines ran nearly all the day at the high speed stated they gave no trouble whatever, and did not necessitate the water service being put into use; and from the time of the start to the *Romeo's* return the supply of steam was ample. One of the most noticeable improvements is that the ship is to be lighted up with gas generated by a chemical process in the engine-room, and which was illuminated by this means during the trip.

Strathallan.—On March 31st, the screw steamer *Strathallan*, built by Messrs. Henry Murray & Co., Port Glasgow, was tried on the Clyde, and attained a speed of nearly 12 knots per hour in water ballast trim over the distance between the Lights and on the measured mile. Her engines, of 99-horse power nominal, were supplied by Mr. William Kemp for the owners, Messrs. James Hay & Sons.

Ranee.—On April 1st, the new screw steamer *Ranee*, built by Messrs. Ramage & Ferguson, Leith, for the Borneo Company (Limited), of London and Singapore, went out on her official trial with very satisfactory results, with over 300 tons dead weight on board, 75 lbs. pressure of steam, and the engines working at from 74 to 78 revolutions. On the run of 35 miles to the Bass Rock and back a mean speed of about 11½ knots per hour was attained. The *Ranee* has been specially built for trading between the Straits settlements and the adjoining islands, and her arrangements are all of the most suitable kind for both cargo and passenger traffic in a hot climate.

Lady Katherine.—On April 1st the new steamship *Lady Katherine*, recently built by Messrs. S. P. Austin & Son, the Panns. Sunderland, for the Earl of Durham, left Sunderland on her trial trip, and after it, proceeding on her first voyage to Aberdeen. The *Lady Katherine* is 211 ft. in length, 30 ft. broad, and 16 ft. 8 in. deep. She was built under special survey to class 18 years at Liverpool, and is a very fine vessel. Her nett tonnage is 615, gross 845, and her deadweight carrying capacity, 1,300 tons. She has a full forecastle, a bridge amidships, and a long raised quarter deck. Nothing is wanted for the working of the ship or the loading or discharging of her cargo. There is on board one of Emerson & Walker's patent windlasses, and two steam winches, with one of Smith's patent donkey boilers, the latter being the workmanship of Messrs. Welford & Wigham, King's House Engine Works, Pallion. The decks are of iron, and the hatches are large in size, and on the self-trimming principle. The *Lady Katherine* is rigged as a schooner, with wire rope for fixed rigging. She has swing davits for her boats. The vessel is adapted for carrying water ballast when necessary, and there are cargo holes in the peaks. The engines have been fitted by the North-Eastern Engineering Company, and are known as Allan's patent. They are 90-horse power. The vessel's steering gear is Holliday's latest patent. The vessel left Lambton docks at half-past 4 o'clock, having on board a cargo of coals for Aberdeen. In the roads the compasses were adjusted. The new steamer was then run south to a mile or two beyond Seaham Harbour, and afterwards north to Souter Point. The greatest satisfaction was expressed with the vessel. The steam generated very rapidly in the boilers, and the average speed attained was about 10 knots an hour. The engines worked smoothly and steadily, making 65 revolutions per minute with steam blowing off.

Glenarm.—On April 4th, the steamship *Glenarm*, a steel screw steamer, designed to carry 300 tons dead weight, and steam 10 knots loaded, went on her trial trip on the Clyde. She has been built by Messrs. H. M'Intyre & Co., Paisley, and engined by Messrs. R. H. Pearson & Co., Glasgow. She is intended for limestone carrying, and is built to the highest class at Lloyd's, having steel hull, decks, boiler, &c. She is the first vessel that has been fitted with the new patent anchor housing, and gave great satisfaction to the Owners at the trial trip.

Fairfield.—On April 4th the *Fairfield* (s), built to the order of Mr. Joseph Brown, of Liverpool, had her trial trip from the Tyne. This vessel will have a carrying capacity of 2,200 tons. She was built by Palmer's Iron Shipbuilding Company, and is intended for the general Transatlantic Trade. During the trip, with 1,000 tons deadweight on board, she made a mean speed of 10½ knots per hour. At the termination of the trip she steamed off to Barrow-in-Furness to take in railway iron for Vera Cruz, after which she will proceed to New Orleans to load a cargo of cotton. She will be under the command of Captain Millard.

Agnes Otto.—On April 4th the new screw steamer *Agnes Otto*, recently built by Messrs. John Redhead & Co., Shields, made a trial trip to sea, and ran over the measured mile at a mean speed of 11 knots per hour, and the engines worked admirably. At the conclusion of the trip she returned to the Tyne to load coals at the Commissioners' Staiths for Odessa. She will be commanded by Captain Sprengle.

Gironde.—On April 7th the trial trip took place of the *Gironde* (s), built for the Cardiff Steamship Company (Limited), by C. S. Swan & Hunt, Wallsend-on-Tyne. The *Gironde* is 200 ft. long by 29 ft. 3 in. broad by 15 ft. deep, and is fitted with long full poop, containing passenger accommodation, full forecastle with ballast, iron maindeck, &c. The machinery, of 100-horse power nominal, is by Mr. George Clark, Southwick, Sunderland. The vessel is classed 100 A 1 at Lloyd's, and also the highest class in the Liverpool Underwriters' Book, and is intended principally for the French trade. The engines worked exceedingly well, and the vessel attained a speed of nine knots loaded, at the measured mile, though there was a considerable sea running.

Drummond Castle.—On April 7 the *Drummond Castle*, the most recent addition to Messrs. Donald Currie & Co.'s Castle Line of South African mail packets, proceeded on her trial trip from Wemyss Bay. This screw-steamer is of the same dimensions as the *Garth Castle*, launched by the same builders (Messrs. John Elder & Co.) in December last. In general arrangement the two vessels are nearly identical, the only difference being that in the *Drummond Castle* the promenade deck of 120 ft. in length is carried across the whole breadth of the ship. Her length is 376 ft.; breadth, 43 ft. 6 in.; depth, 32 ft. 9 in.; and her gross tonnage, 3,706. Her passenger accommodation is for 166 first, 84 second, and 124 third class. The engines, supplied by the builders, are compound, with inverted cylinders, the high-pressure is 51 in., and the low-pressure 88 in. by 4 ft. 9 in. stroke. In a special manner the *Drummond Castle* is fitted like other ships of the fleet, for war purposes, the three decks being of iron, and sufficiently strong to carry guns of heavy calibre, while the watertight compartments, of which there are nine, will be of service in the event of the vessel being fired into and damaged below the waterline. Four trials were made, the mean speed attained being 14·65 knots per hour with 2,000 tons of dead weight on board—a result which was regarded as eminently satisfactory by all concerned. The engines indicated 3,552-horse power.

Lockyer.—On April 11th a satisfactory trial trip was made with this steamer. The vessel left the South Dock, Sunderland, with a cargo of 3,100 tons of coal on board, including bunkers, and, as the wind was a little strong, and the sea rather lumpy, a good test was obtained of all her qualities. The steamer maintained an average speed of 9·4 knots per hour, which, under the circumstances, was considered very satisfactory. The *Lockyer* is commanded by Captain Roseberry.

Saxon Prince.—On April 13, this new screw, belonging to Mr. James Knott & Partners, of Newcastle, left the Tyne on her trial trip. The steamer was built by Messrs. C. S. Swan & Hunter, Wallsend, and is intended for the ore and general trades. The engines are by Messrs. R. & W. Hawthorn. The vessel ran the measured mile, 9½ knots against the tide, and 10¼ knots with the tide—there being a strong sea running at the time, which prevented the full speed being ascertained.

St. Donat's.—On April 13th the screw steamer *St. Donat's*, which was launched from the iron shipbuilding yard of the Messrs. Schlesinger, Davis, & Co., at Wallsend-on-Tyne, about a month ago, had a satisfactory trial trip. The speed of the vessel was tested, and the result was most gratifying to all concerned, the engines working smoothly and well. The *St. Donat's* has been built for the St. Donat's Steamship Company (Limited), of Cardiff, the managers being Messrs. Harrison Bros. & Moore, who also own the *St. Fagan's*, built by Messrs. Schlesinger, Davis, & Co. The leading dimensions of the *St. Donat's* are as follow:—Length between perpendiculars, 260 ft.; breadth, moulded, 35 ft.; depth of hold, 20 ft. 4 in. She classes 100 A1 under special survey at Lloyd's. Compound engines of 140-horse power nominal have been fitted on board by Messrs. Thomas Clark & Co.. of Elswick. Captain Tucker, who has also superintended the fitting out, takes command. As soon as the trial trip was over, she loaded 2,204 tons of coal, and, after adjusting compasses on April 23, had a further trial trip, the speed attained being 9½ knots over the measured mile.

Poh Ann.—On April 18th the steamer *Poh Ann*, built by Wigham Richardsou & Co., for Singapore, went from the Tyne for her trial trip. The results were in every way satisfactory, the speed attained being over 11 knots when deeply loaded, the engines developing a power of between 600 and 700 horses, and running perfectly smooth. She is fitted with all the best appliances, including Emerson, Walker & Co.'s Patent Brass Cone Brake Windlass. The *Poh Ann* was built for Mr. W. Lund, of London, and is the third vessel which he has recently ordered from Wigham Richardson & Co.

Bonnie Doon.—On April 19th the Liverpool, Llandudno, and Welsh Coast Steamboat Company's steamer *Bonnie Don*, built for the passenger service between Liverpool and watering places on the North Welsh Coast, had her trial trip, when she attained the speed of 18½ miles per hour. The *Bonnie Doon*, which was built in 1876, possesses a spacious saloon cabin and upper deck, and is fitted with every convenience for passenger traffic. On Saturday last she started on her first trip, and her sea-going capabilities proved most satisfactory, although she had to contend against a heavy cross sea and wind.

Paul (s. t.).—This powerful paddle tug steamer, built by Messrs. Laird Brothers, of Birkenhead, to the order of the crown agents for the colonies, and intended for service in the Mauritius, made her official trial trip on the Mersey early last month, with very satisfactory results. The *Paul* is 130 ft. long, 25 ft. 10 ins. broad, and 15 ft. 3 ins. deep in hold, and is filled with all the latest and most approved towing appliances, while her cabins are arranged so as to render her suitable for use as a tender or despatch vessel should she be required for such service by the authorities of the island. The engines are two independent sets of angled oscillators on the compound system, each pair having two cylinders, 28½ ins. and 47 ins. in diameter respectively, with 5 ft. stroke, and a working pressure of 60lbs. The engines can be disconnected and worked separately, and are specially adapted for tug steamers, from the great facility with which they are handled when disconnected. The speed was tested by six consecutive runs on the measured mile, which gave a mean of 10.9 knots per hour, the mean power developed by the engines during the same period being 941 i.h.p., and both speed and power in excess of contract requirements. When on trial, the vessel had on board, besides her stores, about 75 tons coals in bunkers, which are arranged to stow nearly double that quantity when required for special service.

Brunswick. (s.s.)—This vessel started on a trial trip on the 9th ult, which lasted from noon till six in the evening. She had over 1,900 tons dead weight on board, the total displacement being 2,920 tons on 17 by 11½ mean draft. The cylinders are 29½ in. and 55 in. by 36 in. stroke, with two single ended boilers 11 ft. 6 in. diameter, and four very large furnaces which are of steel as well as fire boxes working pressure 80 lbs. per square in. The mean revolutions during the run, with one of Oldham's four bladed variable pitch propellers were 63, indicated power 640, speed of vessel 9½ knots north and 8 knots south against a strong wind and tide, mean speed of vessel 8½ knots. The vessel has large and handsome cabins amidship, an extra large and strong iron wheel house aft, also large chart room, wheel house and companions on bridge deck, and there is a powerful straw crane aft. The *Brunswick* is the property of Mr. John Bacon, of Liverpool, and is a sister steamer to the *Stuart*, belonging to the same owner. The arrangement is from the design of Mr. Joseph R. Oldham, under whose superintendence the machinery and hull have been constructed by Messrs. Pickersgill, of Sunderland. The engines and boilers are by Mr. George Clark, and it is sufficient to say that they were never stopped once during the six hours' trial trip, nor gave any trouble, and the vessel then steamed right away on her voyage to Barcelona, under the command of Captain Barnes.

Puerto Huergo.—The trial trip of this iron screw tug, built by Messrs. R. H. Green, Blackwall, for the Harbour Works, Bueno, Ayres, took place on March 23rd, when a mean speed of 9·51 knots was obtained on the measured mile. This tug has been engined by Messrs. Alex. Wilson & Co., Vauxhall Ironworks, with two of their compound surfacing engines, each with cylinders 9 in. and 18 in. diameter, 10 in. stroke, similar to that illustrated in our February number, but with the independent pumps placed between the two engines and common to both, exceedingly handy engines for driving twin screws being thus obtained. The dimensions of the *Puerto Huergo* are, length, 65 ft.; beam, 14 ft.; draught 5 ft. 6 in. aft, 3 ft. 8 in. forward. She was superintended for the owners by Messrs. J. Thompson & Sons, and has since started for the River Plate, the voyages throughout being proposed to be made under steam, though the vessel is fitted also with masts and sails.

BOARD OF TRADE EXAMINATIONS.

Return of Engineers reported to have passed examination under the provisions of the Merchant Shipping Act, 1854, during the month.

General Register and Record Office of Shipping and Seamen,
32, Basinghall Street.

NEW STEAMSHIP COMPANY IN ATHENS.—A large steamship company is about to be formed at Athens to encourage and promote the shipping trade among the greater seaports of Italy, Greece, and the Levant, and generally to compete with the Austro-Hungarian Lloyd, which has hitherto had the chief Shipping trade in these waters. The capital will amount to about 20,000,000f, and is said to have been already subscribed.

Recent Applications for Patents connected with Marine Engineering, Ship Construction, and Mechanical Appliances for use in Ships, from 22nd March to 21st April, 1881.

⁂ Any information regarding these or other patents will be gladly furnished on application.

Two large steamers are about to be built on the Tyne for a German firm at Singapore. The same firm had previously some boats built on the Tyne.

AN order for steamers has just been booked by Messrs. Scott & Co., of Greenock. The order is for ten screw steamers for the Cochin China trade, and has been received through a French firm. Several other French orders are expected there within the next few weeks. The engines for the 10 steamers will be constructed by the Greenock Foundry Company.

SUBSCRIPTIONS.

The Subscription to "The MARINE ENGINEER," payable in advance, is (including postage) Five Shillings per annum.

The Marine Engineer.

LONDON, JUNE 1, 1881.

EDITORIAL NOTES.

IT seems that the adoption of Mr. R. H. Tweddell's system of "hydraulic machine tools" is contributing in no small degree to the successful introduction and manipulation of steel in shipbuilding and boiler yard work. We have so recently described some of these machines that their general features are doubtless fresh in the memories of our readers. The advantages arising from their use in working steel, more especially for punching, shearing, and bending, have been very clearly pointed out in a recent paper read before the Institution of Naval Architects by M. Marc Berrier Fontaine, Ingenieur de la Marine, Toulon. As we commence the publication of the paper itself in this number we need not allude in detail to the results on which M. Berrier Fontaine bases his conclusions, but he distinctly points out the marked improvement due to the substitution of the progressive and steady pressure of hydraulic presses in place of the sharp and violent jar of steam hammers in all work which has to be subjected to sharp changes of form. He also considers as very nearly certain that the action of punches or shears worked on this system must upset the edges of holes or cuts made in steel plates very much less than when the punch or shears are driven by gearing, in which case the tool always reaches its work at considerable speed, producing more or less jar. He makes a further important statement when he adds that the introduction of these machines tends to render less necessary the annealing process. Taking the above results in connection with the recent utterances of Dr. Siemens, it would appear that those who advocate drilling are not going to have it all their own way. As has been frequently pointed out by Mr. Tweddell and others, we should not dispense too hurriedly with punching (which in itself is a cheap and ready form of testing) and, according to Dr. Siemens, is an ordeal which no good steel plate need fear. With care, of course, drilling makes very accurate work, but in comparing the two, good drilling is often compared with bad punching. We have seen some very blind holes in drilled work, and with proper precautions and the use of suitable machinery it is probable that punching will still in many cases be found the best and most convenient mode of making holes. As is often the case, it was not so much the principle which was in fault as that the tools for carrying it out were imperfect. This defect seems now, however, to have been completely and efficiently overcome by the hydraulic machinery, erected under Mr. Tweddell's patents at Toulon Dockyard, and such testimony to their value as that given by Mr. Berrier Fontaine after five years' constant working, is calculated, as we before said, to give an increased impetus to the use of steel in construction, since by their use much of the expense and special precautions hitherto deemed necessary in working up steel are dispensed with.

ROMANCE is seldom more startling than reality, and improbable as many of the fictions in Jules Verne's now well-known whimsical story of "Thirty Thousand Leagues under the Sea" may appear, we are seeing the realization of many of them. Mr. Fleuss has been giving some further practical illustrations at Portsmouth of his new diving dress, which enables him to walk at ease under the water without any connecting pipes or air pump appliances. A diving dress and helmet are only used by Mr. Fleuss for the sake of warmth and comfort under water, neither being in any way necessary to enable him to breathe. The air for respiration he carries down below with him in a compressed condition, concentrated in a little box or tank which is slung over his shoulder like a knapsack. A tube and mouth-piece are so secured to mouth or nostrils that he can draw from his reservoir as desired for respiration, and then return the exhausted gas back again. The impurities formed by respiration are absorbed by a sponge saturated with caustic soda. This apparatus enables the diver to remain under water for a period of three to four hours, without any replenishing of his stock of air. As there are no entangling pipes he can penetrate to situations which would be impossible to the ordinary diver. Mr. Fleuss can descend to the bottom of he Steam Basin, and remain there with perfect freedom of locomotion during any desired time within the before-named limits.

THE same apparatus forms a most valuable protection against suffocating smoke in the case of fire on board ship. Mr. Fleuss in this case dispenses with any external dress, carrying only the same magazine of air strapped to his back, a pair of goggles for his eyes, and the tightly-fitting tube on his nostrils or free respiration. In order to subject this apparatus to a most crucial test, a fire was kindled in a closed shed from all kinds of dockyard waste and refuse, the smoke given off being of the densest and most pungent description. Mr. Fleuss entered the smoking shed, and expressed his willingness to remain there for an hour or more. Those, however, who were witnessing the test considered that the duration of half-an-hour sufficient to prove the perfect success of the apparatus. Mr. Fleuss seemed in no way distressed by the test and could evidently have stayed out his intended time. The result seemed to warrant its adoption as a perfect means of enabling those on board ship to get at fires breaking out in the hold or other inaccessible places. We think this is most important, as the dense smoke usually generated by fire in a closely-packed cargo, invariably drives back those who attempt to get at it, in order to effectually quench it. With this apparatus the position of the fire could be uncovered in spite of the densest fumes, and the hose-pipe thus directed immediately upon the heart of the fire.

SUCH experiments draw our attention to the fact that before long submarine torpedo boats will certainly be constructed, and thus a new and terrible danger menace the fleets of the future. If respiration below the surface of the water and without any communication with the external atmosphere can be so easily maintained for three or four hours, a submarine torpedo boat could noiselessly and unperceived, sink the whole of the strongest ironclad fleet in existence without the presence of the destroyer being once discernible by the ironclads except by its murderous effects. Such a torpedo boat could be dived by compressed air, as in the case of the present Whitehead torpedoes, and could at the same time carry an artificial supply of air, and absorbing apparatus for the vitiated gases, so as to supply the crew for many hours. In fact, we understand Mr. Fleuss is now designing such a boat, and that a Mr. Jones, a Liverpool shipbuilder has already perfected such a model. The prospect for marine battles of the future seems horrible in the extreme. Ironclads with all their gallant crews to be sent to the bottom without warning, and without being able to see the hand that did it. It is difficult to see how such a submarine foe could be combatted at all with the present appliances of defence, but as we have always found that hitherto any mode of aggression has always met its more or less successful means of defence, we will hope that such insidious foes would meet with some novel and formidable form of resistance.

A NEW life-saving beacon is now before the consideration of Admiral Ward and Captain Prouse, the Inspector-General of life-saving appliances. It is the invention of Mr. Sherwell, of Portsmouth, the maker of the Spit bell and other buoys in the Solent. It is considered that many lives might be saved by floating buoys of sufficient dimensions fixed upon or in the neighbourhood of dangerous rocks, banks, or coasts. In some cases safety might be obtained by swimming to such places of refuge when no life-boats or other life-saving appliances might be near. The work also of life boats might be much expedited by landing successive batches of crews upon the buoy, thus saving the repeated journeys of the life-boat to and from the shore. Mr. Sherwell's buoy is a flat-bottomed vessel on which is erected an octagonal dome sufficient to accommodate a ship's crew, and would no doubt be supplied with restoratives and warm wraps for the shipwrecked ones. Access is gained to the structure by means of ladders fitted to the gunwale, and the whole would be surmounted by a bell which would both serve to show the position of the buoy to the shipwrecked sailors, and also serve to indicate the rock or shoal to passing vessels.

THE Italian Government is evidently determined to do all it can to come to the fore in the shape of enterprise both on sea and land. They are now about to undertake an expedition for deep-sea sounding over the whole of the Mediterranean. The necessary arrangements are now being made by Professor Giglioli, the zoologist, at Florence, who will take charge of the biological part of the work. The command of the vessel and the physical part of the work is to be in the hands of Captain Magnagli. It is odd that so little is known of the character of the beds at the bottom of the Mediterranean. The Atlantic though much more inaccessible owing to its greater depth, is still much better known, owing to the frequent soundings occurring during the Atlantic cable laying. There are many scientific questions such as the one whether there is any submarine communication between the Red Sea and the Mediterranean that may be solved by this expedition. The only other known exploration of the depths of this sea is the report of Her Majesty's ship *Porcupine* during a short and imperfect cruise in the year 1870.

THE warrant officers in Her Majesty's Navy seem to have had a substantial grievance of which to complain. They are the only members of the navy that have their pay reduced when in harbour. As their duties are there still as onerous and responsible as when at sea, and as no other officer or man from the admiral to the seaman suffers any similar reduction, it is difficult to explain such an anomaly. The amount of deduction when in port amounts to 9d. a day on the wages, and an extra 6d. a day extra for stores, making a total of 1s. 3d. for each of the days passed in port. As many of the best and oldest of the warrant officers hold harbour appointments they are at once placed on reduced pay just at the time when their services should meet with the best acknowledgment and the greatest comfort. They are now again agitating with the Admiralty for this grievance to be removed. They had already been promised redress by Mr. Ward Hunt, but his sudden death disappointed their hopes. They now, however, hope to have the matter settled to their benefit.

THE iron shipbuilding trade on the Tyne is quite as brisk as ever; most of the firms have orders on hand which will keep their yards busy during the whole of this year.

ON THE EXPERIMENTS WITH THE PERKINS MACHINERY OF THE STEAM YACHT, "ANTHRACITE."

TABLE CONTAINING THE DATA AND RESULTS OF THE EXPERIMENT MADE AT THE NEW YORK NAVY YARD ON THE MACHINERY OF THE STEAM YACHT, "ANTHRACITE," BY A BOARD OF UNITED STATES NAVAL ENGINEERS.—*Continued.*

PER CENTUM OF TOTAL PRESSURE ON PISTONS UTILIZED AS INDICATED AND AS NET PRESSURES.	Mean indicated pressure on the piston of the 3rd cylinder, equivalent to the sum of the indicated pressure on that piston and of the indicated pressures on the pistons of the 2nd and 1st cylinders, reduced respectively in the ratio of the areas of the pistons of the 2nd and 1st cylinders to that of the 3rd cylinder, and for the fact of the 2nd and 1st cylinders being single acting, while the 3rd cylinder is double acting, in pounds per square inch	21·381
	Mean total pressure which applied to the piston of the 3rd cylinder would produce the total horses-power developed by the engine, provided the indicated pressure on that piston was the above 21·381 pounds per square inch	25·591
	Per centum of the mean total pressure on the pistons of the three cylinders utilized as indicated pressure	83·55
	Mean net pressure on the piston of the 3rd cylinder equivalent to the sum of the net pressure on that piston and of the net pressures on the pistons of the 2nd and 1st cylinders reduced respectively in the ratio of the areas of the pistons of the 2nd and 1st cylinders to that of the 3rd cylinder, and with allowance for the fact of the 2nd and 1st cylinders being single acting while the 3rd cylinder is double acting, in pounds per square inch	18·795
	Per centum of the mean total pressure on the pistons of the three cylinders utilized as net pressure	73·44
DIFFERENCE BETWEEN THE WEIGHT OF WATER VAPORIZED IN THE BOILER AND THE WEIGHT OF STEAM ACCOUNTED FOR BY THE INDICATOR.	Difference, in pounds per hour, between the weight of water (1465·11822 pounds) vaporized in the boiler and the weight of steam accounted for by the indicator, in the 1st cylinder at the point of cutting off the steam	831·6088
	Difference, in per centum of the weight of water vaporized in the boiler, between that weight and the weight of steam accounted for by the indicator in the 1st cylinder at the point of cutting off the steam	56·76
	Difference, in pounds per hour, between the weight of water vaporized in the boiler and the weight of steam accounted for by the indicator, in the 1st cylinder at the end of the stroke of its piston	824·6097
	Difference, in per centum of the weight of water vaporized in the boiler, between that weight and the weight of steam accounted for by the indicator in the 1st cylinder at the end of the stroke of its piston	56·22
	Difference, in pounds per hour, between the weight of water vaporized in the boiler and the weight of steam accounted for by the indicator in the 2nd cylinder at the end of the stroke of its piston	562·7648
	Difference, in per centum of the weight of water vaporized in the boiler, between that weight and the weight of steam accounted for by the indicator in the 2nd cylinder at the end of the stroke of its piston	38·41
	Difference, in pounds per hour, between the weight of water vaporized in the boiler and the weight of steam accounted for by the indicator in the 3rd cylinder at the end of the stroke of its piston	147·2538
	Difference, in per centum of the weight of water vaporized in the boiler, between that weight and the weight of steam accounted for by the indicator in the 3rd cylinder at the end of the stroke of its piston	10·05

REMARKS.

Owing to the limited time the *Anthracite* could be placed under the command of the Board of Naval Engineers at the New York Navy Yard, the trial of her machinery was restricted to one experiment, and, consequently, to one set of conditions; but the soundness of the system can be judged only from a number of experiments made under widely varying conditions, and it was the intention of Chief Engineer Loring, had the vessel been long enough at the Navy Yard, to have made a series of experiments on her machinery, with varying boiler pressures and measures of expansion. He intended to have commenced with boiler steam of 74 pounds per square inch pressure above the atmosphere, and, keeping the same measure of expansion, to have made a series of experiments with the boiler pressure increasing 25 pounds per square inch each time; after which, keeping the same boiler pressure, he would have varied the measure of expansion as much as possible, the object being to ascertain whether as good economic results could not be obtained with the lower boiler pressures and less measures of expansion as with the higher boiler pressures and greater measures of expansion, the practically important problem being to ascertain the limit, in both cases, at which increase of economy ceased.

Comparing the economic results obtained during the single experiment made, with those given by ordinary compound engines, it is evident that the latter, with one-fourth the boiler pressure and one-fourth the measure of expansion used with the machinery of the *Anthracite*, produce the power as economically. If the trials are to cease here, the inference follows that the enormous excess of boiler pressure and measure of expansion employed with the machinery of the *Anthracite* have failed to practically realize the economy theoretically predicable, leaving the grave inconveniences of such excess of pressure and expansion unbalanced by any advantage. With this result apparent, it becomes necessary to closely examine the conditions under which the experiment with the *Anthracite* was made.

The boiler pressure does not always represent the initial pressure on the piston, and still less does it represent the mean total pressure on the piston during the stroke; yet it is the latter on which the gain by the use of high pressure must be predicated. Notwithstanding the effect of any superheating which it may be practicable to give in the boiler, the steam in the cylinder is always found to be in the saturated state, that is to say, it has always the maximum density for its pressure, so that it is useless to generate steam at high boiler pressures with the expectation of realizing the economy of producing a given bulk of such pressure over an equivalent bulk of lower boiler pressure, if the former be used in the cylinder with the same mean total pressure on the piston as the latter. To make the mean total pressure on the piston equal in the two cases, the high boiler pressure must be used with a greater measure of expansion than the low boiler pressure, and the gain due to these different measures of expansion may be something or nothing, according to the conditions, but be it what it may, it is entirely distinct from the gain due to the use of steam of the high pressure, *per se*, so that if the high pressure boiler steam be correspondingly expanded in the cylinder to produce the same mean total pressure in its piston as in the case of the low pressure boiler steam, the only gain due to the former will be what results from the higher measure of expansion with which it is used, and not from the higher boiler pressure. This important fact has been overlooked, and a gain under these conditions expected from the high pressure steam corresponding not only to its use with a higher measure of expansion, but also to its generation under a higher boiler pressure. The two cannot be had together. To ascertain what gain can practically be obtained from steam of higher boiler pressure, in function of pressure alone, the experiment must be made using it with the same measure of expansion as in the case of the steam of lower boiler pressure against which it may be tried. This was one of the determinations that Chief-Engineer Loring would have made could he have obtained the *Anthracite* for a sufficient length of time.

Now, during the single experiment with the *Anthracite's* machinery, the measure of expansion employed was so great (25·7098 times) that notwithstanding the high initial pressure on the piston of the first cylinder (201·64 pounds per square inch above zero). the mean total pressure above zero, referred to the piston of the third cylinder, was only 25·591 pounds per square inch above zero, so that in this case the *Anthracite's* engine had no advantage over the ordinary compound engine in function of higher mean total pressure on the piston.

It is quite probable, also, that the measures of expansion employed with ordinary compound engines even when using superheated steam, say from six to ten times, give as high an economy as can be obtained from greater measures, owing to the enormous cylinder refrigeration which attends the use of steam expansively, and which is *pro rata* to the total power developed by the expanded steam alone. If such be the fact, and all experiments thus far show it, then there is no reason to expect any higher economic results from the *Anthracite's* machinery for the conditions under which it was tried at the navy yard than were actually obtained. They were equal to those of an ordinary compound engine, and nothing more.

But it is quite possible that other conditions would have given a higher economy for the *Anthracite's* engine. Had, for instance, the same initial pressure on the piston of the first cylinder been maintained with the steam expanded, say six or ten times only, then, supposing nothing of economy to be lost by the decreased measure of expansion, there would have been the gain due to the resulting higher mean total pressure on the piston in function of pressure only, and to the fact that the same final back pressure would have been a less per centum of the mean total pressure above zero; in other words, more of the mean total pressure on the piston would have been utilized as indicated, or as net pressure. Probably, however, the boiler could not supply the engine with the increased quantity of steam, in equal times, that these conditions would require, and, if it could, the rate of combustion of the coal would have to be largely increased, which would have been attended by a decreased economic vaporization, so that although an economic gain might have been obtained according to the water measure, or weight of steam consumed, yet a loss might have been experienced according to the coal measure. It is so impossible to change one condition in engineering without changing all or many, that it is unsafe to infer what would follow from a given change in one direction. Only the actual trial or appeal to Nature can be relied on each time.

It is true that any better results obtained with the water measure could be obtained with the coal measure also, by reducing the dimensions of the cylinders so as to develop the same power in each case with the same initial pressure on the piston. This, however, requires a new engine, and could not be realized with the machinery of the *Anthracite*.

Nor must the fact be omitted that with each increase in the initial pressure on the piston, the back pressure against it remaining constant, there results increase of cylinder condensation due to the increase in the difference between the temperature of the initial pressure and that of the back pressure. Each theoretical gain is attended with its inseparable practical loss, so that only a very small margin of difference seems possible in any case, and herein lies the true explanation of the failure, total or partial, of the many promising schemes and ingenious mechanisms for cheapening the cost of steam power in fuel.

In comparing the economic efficiency of steam of exceptionally high pressure and measure of expansion against that of steam of comparatively low pressure and measure of expansion, care must be taken that the degree of superheating be the same in both cases. Now, a considerable degree of superheating will increase the economy of any steam from 15 to 30 per centum according as the engine using it is a large or a small one, and superheating is as practicable with steam of one pressure as another. When a high degree of superheating is employed with high pressures and measures of expansion, discrimination must be made between what is due to it and what is due to them.

The great economic gain certain to follow the use of a high degree of superheating is a great temptation to employ it, especially for trials too short to develop its injurious effects on the metal of the cylinder and valves, and on the superheating apparatus itself. A prolonged use of any high degree of superheating has always been followed by such decrease in the durability and reliability of the machinery that, often as it has been attempted just so often has it been abandoned, consequently, notwithstanding the great economy given by it, it is in practical use nowhere. A very moderate degree of superheating is all that can be permanently maintained.

In the boiler of the *Anthracite*, extensive provision was made for highly superheating the steam, the superheating surface being twenty times the area of the grate surface and equal to the water heating surface, an excessive proportion, as compared with the five to eight times of the grate surface, which is usually given with large superheaters. The temperature of the gases of combustion in the chimney during the navy yard experiment averaged 700 degrees Fahrenheit, as obtained from the melting points of different metals suspended in the chimney; yet, notwithstanding the great extent of superheating surface and the high temperature of the gases of combustion upon it, the steam during the navy yard experiment did not appear to be much superheated. This can only be accounted for on the supposition that the steam was very wet when it went upon the superheating surface, owing to the priming or foaming of the boiler. It is greatly to be regretted that the temperatures of the steam on leaving the boiler and on entering the valve chest of the first cylinder were not taken during the navy yard experiment. This is the only important omission in the data; these temperatures would have shown the degree of superheating with certainty, whereas it can now only be inferred. The proper thermometers for the purpose were provided, but they were not inserted in position owing to the want of time to make the extensive connections required.

During the navy yard experiment the boiler was worked with the very moderate rate of combustion of about 12 pounds of coal per hour per square foot of grate surface, which was doubtless above its economic limit. All boilers of this description, that is, composed of small tubes in direct contact with the fire and connected continuously, the boiler not having a proper area of water surface for the disengagement of the steam, nor a proper capacity, and, more especially, proper height of steam room for the separation by gravity of the carried up water from the steam, prime or foam violently when worked above a low rate of combustion. This result is inevitable, and such boilers are only fit for low rates of combustion, and even then require large proportions of water heating and steam superheating surfaces to give good economic vaporizations. As the rate of combustion is increased, so is the priming or foaming, and although the economic vaporization may up to a certain point be maintained by the conversion of the steam superheating into water heating surface by the priming, yet the superheating effect is thereby lost. If the rate of combustion be increased to 15, 20 or 25 pounds of coal per hour per square foot of grate surface the water will be driven by the heat entirely out of the lower tubes, and they will be quickly destroyed. A very great deal of this type of boiler is required in proportion to the power developed. It is neither durable nor reliable, particularly in ignorant or careless hands.

A proper test of this boiler requires it to be worked during a moderate time at the usual rate of combustion for steamers, say 20 pounds of coal per hour per square foot of grate surface. Its durability, its economic vaporization and its steam superheating would then become manifest; but experiments at rates of combustion considerably below what is necessary in practice only mislead.

The *Anthracite* has made two voyages across the Atlantic between Liverpool and New York, say 6,500 geographical miles, and this was intended as a test and proof of the durability and reliability of her machinery. But the voyages were made at an exceedingly low rate of combustion, only about two indicated horses-power being developed for each square foot of grate surface, which evidently does not meet the objections, and leaves the problem just where it was. The fact at issse is: can the vessel without injury to her machinery make two consecutive voyages across the Atlantic at the rate of combustion employed by the ocean steamships running on the same track? The chimney of the *Anthracite* was so short that 12 pounds of semi-bituminous coal per hour per square foot of grate surface was as high a rate of combustion as could be permanently maintained. Had the vessel remained sufficiently long at the New York navy yard for exhaustive experimenting, her chimney would have been temporarily lengthened to about 55 feet above the grate, and all the coal burned that the draught would consume.

The great tendency of the boiler of the *Anthracite* to foam is evidenced by the fact that while the area of the steam port of the first cylinder is $\frac{1}{15}$th of the area of the piston, it was deemed prudent to make the cross area of the steam pipe less than $\frac{1}{27}$th of the area of the piston, thus providing for a great and permanent throttling of the steam beyond the control of the persons operating the engine. The extent of this throttling was such that whereas the boiler pressure during the experiment was 331·23 pounds per square inch above zero, the initial pressure on the piston of the first cylinder was 201·64 pounds, the throttle valve being wide open, the difference was 129·59 pounds.

That the steam had but little superheating when entering the first cylinder, probably not exceeding 50 degrees Fahrenheit, the most of which (35 degrees) was due to the throttling, appeared from all the indications. The packings of the valve stems and of the piston rods were unaffected; the steam when blown into the air did not look as though it was much superheated, and the condensation of steam in the first cylinder was enormous, exclusive of what was due to the developement of the power. This condensation at the point of cutting off the steam in the first cylinder was 56·76 per centum of the entire weight generated in the boiler, and was maintained to the end of the stroke of the piston of that cylinder. In the second cylinder, owing to re-evaporation, this condensation fell at the end of the stroke of its piston to 38·41 per centum of the entire weight generated in the boiler, while at the end of the stroke of the piston of the third cylinder it fell further to 10·05 per centum by the continuance of the same cause.

This enormous cylinder refrigeration was due to the enormous measure of expansion (nearly twenty-six times) with which the steam was used, to the great difference between the temperature of the initial steam in the first cylinder and that of the back pressure steam in the third cylinder, and to the small dimensions of the cylinders whereby their inner surfaces, including the extensive surfaces of their disproportionately large steam passages, became very great relatively to the weight of steam contained. To counteract these cooling causes would require the steam to be very highly superheated, and provision for obtaining that effect was made by giving the boiler an enormous extent of superheating surface, but the necessary superheating was not obtained with the water carried at the experimental level, due doubtless to the priming or foaming of the boiler, notwithstanding the great throttling with which the steam was used.

A sensible proof of the enormous cylinder condensation in the case of the experiment on the *Anthracite* at the New York navy yard was furnished whenever a set of indicator diagrams was taken. On opening the cock in the indicator pipe of the first cylinder a steady flow of water streamed from it, of the full area of the cock opening, and with considerable velocity, and continued unabated as long as the cock remained open, making the taking of diagrams very troublesome. When the cock in the indicator pipe of the second cylinder was opened, the same flow of water took place, and continued as long as the cock remained open, but the issuing quantity of water was much less and it flowed with much less velocity, the pressure being greatly less than in the first cylinder. When the cocks in the indicator pipes of the third cylinder were opened, no water came forth at any part of the stroke of the piston.

The engine during its working gave no indication of the enormous quantities of water of condensation passing through the cylinders; there was no slapping noise or noticeable jar, the entire mass of steam condensed during the steam stroke of the pistons being re-evaporated during the latter part of that stroke and the whole of the exhaust stroke under the lessening pressures by the heat contained in the water of condensation and in the metal of the cylinders on which this water rested.

The theoretical gain due to very high steam pressure worked in a cylinder with a low and constant back pressure, and to using it very expansively, is practically lost in greater refrigeration which inseparably attends both to a greater degree than with steam of lower pressure worked less expansively, and although the resulting condensation may be in a great measure prevented by previous superheating, yet if the same quantity of superheating be given to the lower pressure and less expanded steam, the latter would be proportionally benefitted, and the relative economy of the two perhaps not much changed.

It is of the greatest importance to mankind that there shall be discovered the pressure of steam, the measure of expansion, and the degree of superheating which will produce the highest economic results from the fuel, without prejudice to the durability and reliability of the machinery, and without requiring exceptional care and skill in its management. The attempt made to solve this problem by the construction of the machinery of the *Anthracite* is in the right direction, and most praiseworthy, and it will be a subject of lasting regret should a series of exhaustive experiments be not made with it. The mechanism is at hand, and all that is needed are the services of skilled and sagacious experimenters animated by the love of truth alone.

TRIAL OF SCREW PROPELLERS.—Captain George Peacock, F.R.G.S., of Starcross, Devon, has lately had built by Mr. Dixon, of Exmouth, a steam galley for a pleasure yacht on the river Exe, in order to try a "cycloidal propeller" invented by him some years since. The engine and boiler, of about 4-horse power, were constructed by Messrs. Cochran & Co., of Birkenhead. The yacht is called the *Flying Dutchman*, and took the water on Tuesday last in the Birkenhead Float, when a series of trials was instituted with three different kinds of propellers. The first trial, of four runs, was made with an ordinary two-bladed screw propeller of the most approved form and pitch; the next with a three-bladed propeller of same area; the latter beat the former by three quarters of a knot an hour, and with less vibration; four runs were also made with this propeller, which concluded the trials for Tuesday. On Wednesday, May 18, Captain Peacock's patent cycloidal propeller, of same area as the other screws, was attached to the shaft, and four runs made, beating the first screw by nearly two knots an hour, and the second by upwards of a knot, and with scarcely any perceptible vibration. The draught of water was the same on all three trials; on one occasion, going before the wind, it is mentioned that she made with the cycloidal propeller nearly 10 knots.

THE INSTITUTION OF CIVIL ENGINEERS.

ON TORPEDO BOATS AND LIGHT YACHTS FOR HIGH SPEED STEAM NAVIGATION.

AT the meeting on Tuesday, the 10th of May, Mr. Brunlees, F.R.S.E., Vice-President, in the chair, the paper read was by Mr. John Isaac Thornycroft, M. Inst., C. E.

The total weight or displacement of a vessel was divided by the author into three components:—1st, the structural hull; 2nd, the propelling machinery and apparatus; 3rd, the load. In considering how the two conditions of lightness and sufficient power might best be attained, the author directed attention chiefly to the treatment of the second component, and the means which had been adopted for reducing the weight of the propelling machinery and apparatus, and, in consequence, the weight of the hull also. For this purpose, rapid combustion of fuel, sub-divided flue way, high-steam pressure, and high-speed of engine had been brought into action, following the initiative taken in the perfecting of the locomotive engine as the embodiment of extreme lightness and concentration of power. For promoting the draught of marine boilers, the fan appears to be the most convenient instrument for forcing air into the stokehole, which was thus kept moderately cool. The author devised the fan-blast in this form for the boilers of the yacht *Gitana*, built by him in 1876, and it had been found to work efficiently. The pressure of the blast was measured by a column of water of from 3 in. to 6 in. high. The greater part of the pressure was exerted in overcoming the resistance of the flue-tubes of the boiler.

The author proceeded to examine into the relative weight and form of hull best adapted for carrying the load and the machinery. He illustrated by diagrams the form of hull employed for second-class torpedo boat, showing the distribution of displacement with regard to the lengths of the boats, with a curve for each boat, in which the ordinates represented the areas of immersed section. A curve, constructed in this way, taken from the *Iris*, was exhibited. Though the most favourable position of the propeller for high speeds was astern of the rudder, yet it was frequently preferred, for the sake of better steering qualities, to place the screw in advance of the rudder. On the question of immersion, the author referred to experiments recently made by him on a model propeller; from which it appeared that when the propeller was totally immersed, the useful effect was equal to about seven-tenths of the power expended; and when it just broke the surface of the water, the efficiency did not exceed five-tenths of the power expended.

The light yacht, *Gitana*, was described in its main features. The hull was 86 ft. long at the water line, and a breadth of beam of 10½ ft., the extreme breadth being 13 ft. 3 in. The draft was 1 ft. 1½ in. forward, and 4 ft. aft; the displacement was 29 tons. The engines were compound, with an intermediate receiver, and injection condenser; having three cylinders—one 13½ in. high pressure, and two 15 in. low pressure, with a stroke of 16 in. The air pump was 23 in. in diameter, with a stroke of 3 in. The blowing fan was 3½ ft. in diameter, driven directly from a 5 in. steam cylinder, and made 900 revolutions per minute. The propeller was a screw of 5½ ft. in diameter, with a pitch of 8½ ft., placed abaft the rudder. The boiler was of the locomotive type. The framing of the engine consisted of small steel columns, directly connecting the cylinders with the bed-plate, and placed as near to the main bearings as possible. These columns were braced together near the centre of their length, and were only adapted to resist vertical forces. The framing depended for its transverse stability on its connection with the hull, to which the cylinders, and lower ends of the guide bar, were fastened by stays. For securing lightness of moving parts, the pistons were made of wrought steel; the piston-rods and connecting-rods were also of steel, the piston-rods being bored out. The cranks, the crank-pins, and the lower halves of the connecting-rods, were balanced by cast iron balance-weights, secured to the cranks by steel bolts.

A first-class torpedo-boat was next described, 87 ft. in length, with 10½ ft. beam. The engines were compound with a receiver, having two cylinders respectively 12¾ in. and 20⅝ in. in diameter, with a stroke of 12 in. The condensing water was forced through the condenser by a centrifugal pump, assisted by a special form of grating, which by gradually expanding openings, converted the external relative velocity of the water into pressure. The slide valves of the engines were balanced by being placed under bridges, which were made with recesses corresponding to the ports in the cylinders, as used by Mr. Wilson, of Patricroft. The four packing-rings of the pistons were of Perkins' metal. The feed pumps were worked by a cast-iron worm on the engine shaft, geared into a wheel of phosphor-bronze, on a shaft having a crank at each end to work two feed pumps. The engine-room also contained a bilge-pump, and an air-compressing pump, with a separate engine for charging torpedoes. The propeller was constructed with three blades, and was placed forward of the rudder; it was 4½ ft. in diameter, with a pitch of 6 ft. The boiler was of the locomotive type, with a working pressure of 126 lb. A rose with an ejector was provided, to extinguish the fire in cases when it was required to be put out, and could not be drawn. There were self-closing ashpit-doors, preventing the return of vapour to the stokehole. A passage to the deck was also provided, to facilitate the escape of the steam discharged in the event of a tube giving way.

Experiments had been made at Portsmouth to ascertain the performance of the boilers of the first-class torpedo boats, the results of which were given as in the annexed table.

The influence of the pressure of air employed on the rate of evaporation and of combustion, and on the temperature of the gases leaving the boiler, was clearly manifested. The measurement of the pressure in the stokehole, ashpit, and fire-box showed that of the initial pressure the resistance of the tubes accounted for about seven-tenths of the whole, the resistance of the fire and fire-bars being only about one-tenth. The loss on entering the ash-pit appeared too large, and the indicated deficiency of pressure under the bars was perhaps partly due to the comparatively high velocity of the air at this part of its transit. The second-class torpedo boat was 60 ft. in length, with a beam of 7¼ ft.; the draught was 12½ in. forward, and 3 ft. 4 in. aft.; the displacement was 10·6 tons. The engines were compound, surface-condensing, and worked up to about 112 indicated H.P. The working cylinders were 7 in. and 11 in. respectively in diameter, with a stroke of 8 in. The air-pump, actuated by levers. was 7 in. in diameter, with a stroke of 2 in. Two feed-pumps were worked by worm and wheel, as described for the first-class boat. The circulation of the water in the condenser was effected entirely by an apparatus by which the external motion of the water when the boat was moving was utilized. An ejector was also fitted for removing air from the water-space of the condenser, which was partly above the load water-line. By this apparatus sufficient circulation could be maintained, when the boat was at rest, to condense any steam that might be required to be condensed in order to prevent its escaping into the air. A small engine was used for blowing the fires, similar to that described for the first-class boats; but it was made to drive two pumps, which could be connected when required. These boats were designed to be carried on board ship, and they required to be slung overboard complete and ready for use. This condition involved their being subjected to considerable stresses, and the effect of their being thus suspended was illustrated by diagrams. The paper concluded with three tables—of the proportionate weight of the hulls of sea-going vessels, and the torpedo-boats and yachts, that had been described; of the relative performance and weight of steam-vessels and locomotives; and of the relative displacement and performance of steam-vessels.

MILD STEEL IN FRENCH ARSENALS.

On the Use of Mild Steel for the Construction of the Hulls of Ships in the Arsenals of the French Navy.[*]

By M. MARC BERRIER FONTAINE, Member.

THE Council of the Society having thought that some of its members might take some interest in being acquainted with the conditions under which mild steel is actually in use in the arsenals of the French Navy for the construction of the hulls of ships of all classes, I am pleased to be able to satisfy the wish which has been expressed to me on this matter, after having obtained from the Ministry of Marine the necessary authorization.

I doubt, however, whether the information which it will be possible for me to give in the following note will add any very important matters of experience to those which have already been set forth by Messrs. Barnaby, Riley, Denny, Martell, and West, in the remarkable communications which have been read by them at former meetings of the Institution.

If, in fact, the French Navy can justly claim the merit of having been the first to undertake boldly the substitution of mild steel for iron in the construction of the hulls of its largest fighting ships, it is necessary to admit that the British Admiralty very quickly followed in this line.

If the French builders on their side can pride themselves on having been the first in a position to produce plates, angle-irons, and bars of all sections, presenting all the qualities of ductility, malleability, and homogeneity necessary to permit of their being used safely in the construction of warships, without its being necessary to have recourse to too delicate methods of work, it is also just to do credit to the wonderful rapidity with which the iron works of Great Britain have succeeded in obtaining steel plates and steel angle-irons, fulfilling in the most satisfactory manner all the difficult conditions which had been clearly pointed out to them by the Admiralty.

We may now therefore, I think, admit that in a general way the experience and skill of the mild steel makers are about equal on the two shores of the Channel, and that a corresponding equality presents itself in the experience and skill of the builders who have been able to work this steel in the naval yards, both public and private, of the two countries.

It was on March 10th, 1873, that the contracts were entered into at Lorient for furnishing the plates, angle-irons, and mouldings in steel, necessary for the construction of the first-class armour-plated ship, the *Redoubtable*, which is entirely built of steel, with the single exception of the external plating of the wetted hull down to the lower armour shelf. The provision of this material it was possible to divide even at this time between two different works, that of *Creusôt* and that of *Terrenoire*. The keel of the *Redoubtable* was laid on July 10th in the same year. About the same time, in August, 1873, the keels were laid of two other large vessels, also built throughout of steel, with the exception of the external plating of the wetted hull—the *Tonnerre*, a coastguard ship of the first class, at Lorient, and the *Tempête*, a coastguard ship of the second class, at Brest. I may here mention that the idea of the almost exclusive employment of steel in the construction of these first three ships belongs exclusively to their designer, Mr. L. de Bussy, then naval engineer at Lorient, and now director of naval construction at Paris. The quality of the steel employed in these constructions and the processes of working it have been completely described by M. J. Barba, then naval engineer at Lorient, and now chief engineer of the works of *Creusôt*, in his "Account of the Use of Steel in Naval Construction."[†] In the month of October, 1874, Admiral Sir W. Houston Stewart, Controller of the British Navy, and Mr. N. Barnaby, Director of Naval construction, took the opportunity of seeing for themselves, and of studying on the spot, the use of steel in the dockyards of Lorient and Brest. In the excellent communication on iron and steel for shipbuilding, read on the 19th of the following March before this Institution,[*] Mr. Barnaby gave an account of his observations during this visit, and pointed out in the clearest and most precise manner to the steel makers of Great Britain all the indispensable conditions which must be satisfied by the plates and mouldings in steel, so that they may be used with full confidence in the construction of the largest ships. The conditions to be fulfilled having thus been clearly stated, it was not long before the steelmakers of Great Britain were in a position to satisfy them. The Landore-Siemens Company was the first to be able to fulfil them, and before the end of 1875, that company was in a position to contract with the Admiralty for the plates and angle-irons necessary for the construction of two cruisers of high speed, the *Iris* and the *Mercury*. These plates and angle-irons were made from steel obtained by the Siemens-Martin process. Shortly afterwards the Bolton Steel Company was in its turn able to produce, by the Bessemer process, plates and angles satisfying all the requisite conditions. The Steel Company of Scotland, Butterley Company, and other important works have also entered into the same business, and we are at last able to put full trust in the quality of steel furnished by these different Works, as is now fully admitted by the Constructors of the Navy, the officers of the Board of Trade, of Lloyd's Registry, and the Liverpool Registry, and all the most competent authorities. Nothing could well be more instructive than a comparison of the doubts and hesitation expressed by Mr. Barnaby in 1875, and the unlimited confidence expressed by Messrs. W. Denny and West in 1880. This is perhaps the best proof that could be given of the marked progress made in England in this matter in the short space of five years.

But while the steelmakers of Great Britain were thus progressing so rapidly and remarkably in the quality of their output, their competitors on the Continent were far from remaining inactive. On our side of the Channel, too, the manufacture of steel continued to make important progress, especially in respect of the homogeneity and proved uniformity of the material turned out.

The steady and progressive improvement in the qualities of steel which are delivered to the French Navy cannot be doubted. It is established by the result of all the trials to which the material has been submitted under the eyes and under the direction of the naval inspectors before leaving the works. The proportion rejected by these has been steadily diminishing, and is now very small indeed. The ironmasters, moreover, have so completely mastered the quality of their steel that they can obtain with certainty qualities satisfying all the conditions for acceptance imposed upon them by the Navy,[†] although not giving results markedly superior to those required by the conditions. For instance, for plates from 6 mm. to 20 mm. thick, for passing which the breaking weight must reach at last 45 kilogs. per square millimetre, and the extension at the moment of breaking must be at least 20 per cent., the ironmaster will naturally endeavour to obtain plates which give under test results slightly in advance of those which have been pointed out, so as to make sure that the plates will not be thrown upon his hands; but he is now able to settle beforehand his process of manufacture, so as to obtain products of uniform equality with such precision that he can cut down almost to nothing the margin of safety that he needs to reserve. He will thus make his arrangements to produce plates, which, upon testing, will seldom give more than 48 or 49 kilogs. breaking weight per square millimetre, or more than 22 or 23 per cent. of corresponding extension. This certainty in the processes of manufacture, moreover, is not the peculiar possession of any one manufacturer. All the works without exception, which furnish the navy with plates and moulded bars, are at the present moment in a condition to produce with certainty material whose tests will lie between limits equally close. This has been proved in the clearest manner by the results of the tests constantly made in the different works.‡ Thus not only do the products of any definite works present a constancy of quality and remarkable homogeneity, but this constancy of quality and this homogeneity may also be found in the produce of all the different works to such an extent that it would not be possible to distinguish the one from the other, the produce of different works, were it not for the manufacturers' mark stamped on each plate or each bar.

---

[*] Transactions Institution of Naval Architects, vol. xvi., 1875. p. 131.

[†] See the Conditions of Acceptance, Appendix A.

It must be added that this valuable quality of almost perfect homogeneity is not a consequence of the exclusive use of any particular process of manufacture. Steels made by the Siemens-Martin process and those turned out by the Bessemer process may now be regarded as absolutely equal in this respect, and the navy has been able now for several years to admit with complete indifference the material turned out by both these processes, the names of which are not even mentioned in the terms of contract. Several manufacturers employ both processes simultaneously. If some of them reserve their Bessemer converters for the production of steels relatively of inferior quality, such as those for rails, and keep their Siemens-Martin converters for the production of superior qualities which have afterwards to be rolled into plates or bars for ships, other works, exactly reversing this plan, make rails from their Siemens-Martin Steel, and reserve the produce of their Bessemer converters for plates and bars for the Navy.

(*To be continued.*)

THE INFLUENCE OF CUT-OFF AND LENGTH OF CONNECTING ROD ON THE WORKING OF STEAM-ENGINES.

By C. E. STROMEYER, Esq., Engineer Surveyor to Lloyd's Register.

[Read at the Twenty-Second Session of the Institution of Naval Architects, 7th April, 1881; the Right Hon. the Earl of RAVENSWORTH, President, in the Chair.]

IN bringing before your notice a few tables which I have compiled on the friction of some of the working parts of an engine and the uniformity of motion, and their relations to the cut-off and length of connecting rod, I hope that the information may be found not without value in the present day, when, as it appears, both the type and the pressure of steam-engines may undergo a radical change.

The classification of the different frictions occurring in an engine has seldom been attempted in such a manner as to make apparent their relations to the several dimensions; it will therefore be necessary to submit a few remarks on this subject before explaining the tables and diagrams, and the principle on which they have been calculated. The frictions of an engine can be divided as follows:—

Those depending only on the dimensions; those which depend chiefly on the weights; and those which depend partly on the dimensions, but chiefly on the adjustments, such as the packing of glands and pistons. Most of this last-mentioned friction is a function of the skill or carelessness of the men who attend to the working, and is, therefore, inestimable, but there are certain limits below which it can never fall; they depend on the dimensions and nature of the surfaces, and on the lubricants. Nothing, or very little definite, is as yet known about this subject, but it is at least probable that the friction increases both with the initial pressure and with the circumference of the rod or of the piston, and also that the lengths of the packing in the glands and heights of piston rings are important factors, though whether the friction increases directly or inversely as the length, or whether there is a certain length which gives the best result, is not known.

Of the other frictions, that produced by the weights of revolving and sliding machinery can be so easily ascertained for individual cases, that it will not be necessary to refer to it here. Then there is the slide valve friction, which does depend to a great extent on the expansion of the steam, but is entirely independent of the length of connecting rod. The remaining frictions are produced between —1, crosshead and guide bars; 2, gudgeon and crosshead; 3, bottom end and crank pin; and 4, crank shaft and main bearings. As the coefficient of friction has been pretty accurately determined, and as it is at least certain that it will not greatly vary in different engines in which the same lubricants are used, the above losses can all be brought into formulæ, comparing them with the indicated work and with other engines in which the dimensions have been altered. The following short list contains the notations employed in the formulæ, on the friction and on the uniformity of motion:—

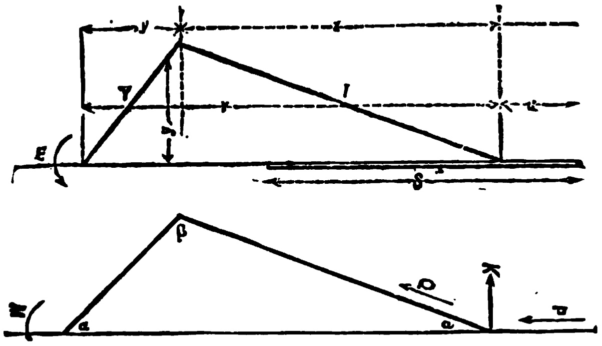
s = length of stroke = $2r$ = twice length of crank.
l = length of connecting rod.
P = load on piston rod.
K = normal pressure on guide bars.
Q = thrust in connecting rod.
M = turning moment on shaft.
u = position of top end from top of stroke.
h, v, x, y, fixed position of crank pin.
α = angular position of crank.
β and γ = complementary angles to α.
ϕ = coefficient of friction.
M = mass of piston and rods.
T = moment of inertia of fly-wheel.
I = moment of inertia of connecting rod.
I H P = indicated horse-power.
ω = angular speed.
$d\,2$ = diameter of crank pin.
$d\,3$ = " crank shaft.
$d\,4$ = " gudgeon.

It will be seen that— $\cos\alpha = \frac{y}{r}$,

and by making several simple substitutions it will be found that—

$$\cos\alpha = \frac{u^2 + v^2 - l^2}{2\,v\,r}.$$

With the help of this formula the values of cos α, α, sin α were tabulated for twelve different values of u and for eleven different values of l, ranging from $\frac{3}{4}\,r$ to ∝. Then diagrams were constructed representing the friction according to the two following formulæ:—



$$\text{Guide friction } d f_1 = -\phi\,K\,d u = -\phi\,P\,\frac{h}{x}\,d u.$$

Crank pin friction

$$d f_2 = -\phi\,Q\,\frac{d^2}{2}\,d\beta = -\phi\,P\,\frac{d^2}{2}\,\frac{L}{x}\left(1 + \frac{y}{x}\right) d\,\alpha.$$

The friction at the journals is almost the same as that of the crank pin, and the friction of the gudgeon is so very small that they have not been worked into the shape of a table. The formulæ are—

$$\text{Crank shaft friction } d f_3 = -\phi\,Q\,\frac{d_3}{2}\,d\alpha = -\phi\,P\,\frac{d_3}{2}\,\frac{l}{x}\,d\alpha.$$

$$\text{Gudgeon friction } d f_4 = -\phi\,Q\,\frac{d_1}{2}\,d x = -\phi\,P\,\frac{d_4}{2}\,\frac{l y}{x^2}\,d\alpha.$$

With the help of the table containing the values of α, cos α, sin α, h, y, and x, could easily be found, and with their help about 130 diagrams were constructed; the area of each one was measured, compared with the indicated work, and the result given in Tables and Diagrams I. and II. As will be seen, Tables I.*a* and II.*a* are worked out for six different lengths of connecting rods, varying from ∝ to $\frac{3}{4}$ of piston stroke, and for ten different diagrams, the cut-off varying from $\frac{1}{10}$ to $\frac{10}{10}$, and also for a triangular diagram. Tables I.*b* and II.*b* will probably be found more handy than the others, marked I.*a* and II.*a*, as here the values are classed according to the mean pressures, and not according to the cut-off; in every other respect the two tables are identical. There is a decided difference in the crank-pin friction during the up and the down stroke, the loss during the down stroke (irrespective of piston weight) being greatest, but as there are only few engines which work with steam on one side of piston, the tables have been simplified by giving the mean values. The use to which they can be put will be plain from their appended explanation, but in case it should be thought necessary to find the friction for diagrams which are not contained there, the following examples may be of help:—

---

‡ See Appendix B for an analysis of a great number of these tests applied to steel plates and bars delivered at the Toulon yard.

In the diagram of an engine in which the connecting rod = 2 stroke (Fig. 3) and cutting off at $\frac{3}{10}$ stroke with a back pressure of ·12 P, the mean pressure would be ·40, because the area of A B C D E is ·52 P., of E F G D it is ·12 P., and therefore that of A B C G F is ·40 P. The coefficients are—

	Crank friction.	Guide friction.
For the first area	1·074 ...	·187
For the second	1·018 ...	·184
The coeff. for the difference is ...	1·091 ...	·185

because—

$$\frac{1·074 \times ·52 - 1·018 \times ·12}{·52 - ·12} = \frac{·43632}{·40} = 1·091,$$

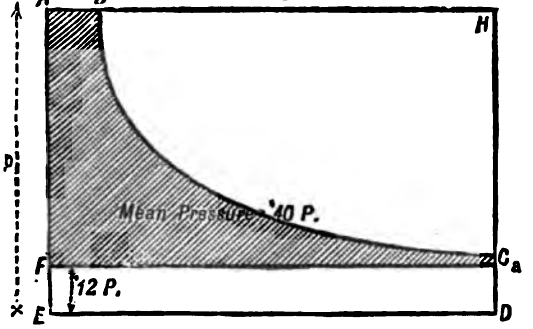
because—

$$\frac{·187 \times ·52 - 1·94 \times ·12}{·52 - ·12} = \frac{·07396}{·40} = ·185.$$

The friction of a diagram of the shape of Fig. 4 can be found in the same way. Let the initial pressure be represented by 1 and the end pressure by ·5, then the mean pressure will be ·75, if the connecting-rod = 3 strokes, the coefficients will be as follows:—

	Crank friction.	Guide friction.
Triangular diagram	1·006 ...	·194
Lower diagram	1·008 ...	·194
Coeff. of entire area	1·007 ...	·194

Fig. 8.

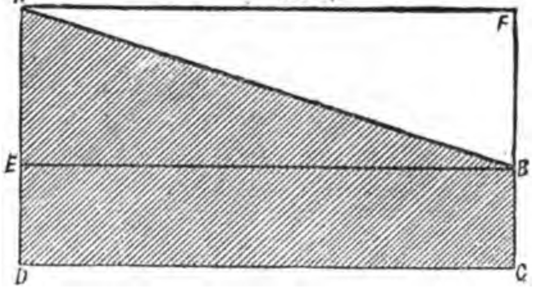


Had the area of A B E been made equal to the area of B C D E, and the one subtracted from the other, very little would have been left; such a diagram would represent the action of the oscillating masses; this shows that they produce very little extra friction. When the connecting rod is shortened as much as ¾ the length of stroke, this friction will only amount to as much as would be due to a parallel diagram, of which the height represents ·023 of the greatest pressure exerted by such masses, so that they may safely be neglected. The same is nearly the case with the weights of piston, rods, and shafting; as long as the up and down pressure on the piston is greater than these combined weights they will have no effect, because they only increase the load during the down stroke, and diminish it during the up stroke; but as soon as it grows smaller than the weights, they alone produce the friction, and the steam pressure only alters the distribution during the up and down stroke; this will, perhaps, explain the reason why some engines, especially land engines, lose comparatively more when running light than when loaded. If, however, the engines work horizontally, the weight of part of the connecting and piston rod will either constantly increase or diminish the friction, which depends on whether the crosshead is working on its lower or upper surface. The crank pin friction will also be increased by an amount which is probably a little less than that due to half the weight of the connecting rod, but can only be worked out for special cases. In double and treble engines the friction of the journals is slightly reduced, for it appears that in non-expansive engines with two cranks at right angles, the loads on them balance each other during two quarters of each revolution; in treble engines two cranks are always balanced, and it is therefore probable that in the former case a part (depending on the position of the journals) of one-half of the friction, and in the latter a part of two-thirds of the friction is saved. The following examples will still further explain the Tables, while showing to what use they may be put. The dimensions of one of these engines are taken from the supplement to Burgh's "Modern Marine Engineering," those of the other from *Engineering*, vol. xxi. p. 129, exemplifying two extreme cases of engine proportions. As regards the size of crank shaft in relation to the stroke, I have assumed the friction to be $\frac{1}{30}$ of the load, and have worked it out for two cut-offs in each case, with the following result:—

Ship's Name	Tug *Filga*, Fig. 5.		*Bell Bird*, Fig. 6.	
Piston Stroke... ...	12 in.		12 in.	
Connecting Rod ...	24 ,,		28 ,,	
Diameter of Crank pins	7 ,,		2½ ,,	
$l : S$	2		2⅓ ,,	
$\frac{d_2 + d_3}{2s}$	1 1·71		1 4 8	
Mean Pressure ...	·847	·50	·847	·50
Guide Friction : I.H.P.	·0103	·0093	·0083	·0071
Crank Friction : I.H.P.	·0903	·0996	·0180	·0177
Total Friction : I.H.P.	·1006	·1089	·0263	·0254

In the case of the tug *Filga* the friction is about four times greater than in the other boat. You will see that the chief reason is the very short stroke and large crank pin; it therefore is probable that the friction might have been considerably reduced if the height of engine and length of the stroke had been increased a little, unless this would increase the gland and piston friction, so that possibly the total loss would have been greater instead of less; but putting that aside and assuming that there was no room for heightening the engine, then the stroke could with slight advantage have been lengthened at the expense of the connecting rod.

Fig. 4.



The following numbers will show that the engine might have been improved, but only slightly:—

Stroke	12 in.	13·5	14·6	15·5
Connecting rod...	24 ,,	20·25	17·5	15·5
Diameter of Pin	7	7	7	7
$l : S$	2	1·5	1·2	1·0
$\frac{d_2 + d_3}{s}$	1 : 1·71	1 : 1·93	1 : 2·10	1 : 2 20
Mean Pressure...	·50	·50	·50	·50
Total Friction ...	·1089	·1023	·1011	·1013

So that as far as this friction is concerned, a stroke of 14·6 inches, with a connecting rod of 17·5 inches, will give the best results; but then the engines would not work so uniform as they now probably do, which will be seen later on. If, however, the above proportions are the most advantageous that can be adopted, such engines will never compare favourably with ordinary ones, especially as the chief friction is to be found in the bottom ends, where nobody wants it.

Returning now to the Diagrams I. and II., it will be seen that the crank-pin friction is least for an engine cutting off at about half-stroke with an infinitely long connecting rod, and that even when it is about twice as long as the stroke, which is now the general practice, the friction is less than it would be with a full diagram and a long rod. So long as the cut-off is kept above $\frac{3}{10}$, and the connecting-rods are longer than $\frac{3}{2}$ of stroke, there is little extra friction to contend with, either in single, double, or treble engines; the guide friction will also be comparatively small if those limits are not overstepped, though the length of the connecting rods has here a far greater influence.

Before referring to the uniformity of motion of engines, I shall have to draw your attention to the oscillating masses, and their influence on it.

All oscillating masses store up energy at the commencement of the stroke and redeliver it at the end; if there are other which just then are absorbing energy it will not be visible in the diagrams of the turning movement of the crank, and for such cases only a coefficient expressing the necessary inertia of a fly-wheel will be of value, while in other cases, where these masses can of course vary within wide ranges, just as the stroke and cut-off have been made to vary, the determination of such a coefficient would be very complicated and would require enormous tables, and even then they would only be valuable in so far as they could show some general law. Retaining, then, all the previous notations, the downward piston speed would be—

$$\frac{du}{at} = \frac{du.da}{da.dt} = r \sin a . \omega.$$

the downward acceleration is

$$\frac{d^2u}{dt^2} = r\omega \frac{d(\sin a)}{dt} = r\omega^2 \cos a,$$

and the force which the accelerated mass m of piston and rods exerts is

$$m \frac{d^2u}{dt^2}$$

producing a negative turning moment

$$M = -m r^2 \frac{\omega^2}{2} \sin 2a.$$

In an engine with two cranks at right angles this value would be—

$$M = -\frac{r^2\omega^2}{2} \sin 2a (m_1 - m_2).$$

If the moment of inertia I_1 of the connecting rod, taking its top end as fulcrum, be substituted for m_2, the turning moment produced in a single engine will be—

$$M_1 = -\frac{r^2\omega^2}{2} \sin 2a \left(m_1 - \frac{I_1}{l^2}\right).$$

$$\text{Double Engine } M_{II} = -\frac{r^2\omega^2}{2} \sin 2a \left(m_1 - m_2 - \frac{I + I_2}{l^2}\right).$$

$$\text{Treble Engine } M_{III} = -\frac{r^2\omega^2}{2} \left[\sin 2a \left(m_1 - \frac{I_1}{} \frac{m_2 + m_3}{2} + \frac{I_2 + I_3}{2\,l^2}\right) - \cos 2a \sqrt{\frac{3}{4}} m_2 - m_3 + \frac{I_3 - I_2}{l^2}\Big)\right].$$

If, however, the weights in the double and in the treble engines are equal, both M_{II} and M_{III} will equal nil, that is, the oscillating masses may be neglected in such engines when inquiring into the uniformity of motion. However, when these weights exert no disturbing influence on the turning moments they act as fly-wheels would do, and as the effect is very simple, and as I have never seen them looked at in this light before, I hope a short development of the principle will not be out of place.

(*To be continued.*)

"CITY OF ROME."—The Inman liner, *City of Rome*, 8,500 tons, will be launched at Barrow on June 14.

THE "POLYPHEMUS."—Preparations are now being made at Chatham Dockyard for the launch of the armour-plated torpedo ram, *Polyphemus*, which is to take place on June 15.

EARLY on the morning of May 17th, the steamship *Queen of the Bay*, bound from Penzance to Scilly, broke her shaft during strong weather off the Rundle Stone. Sails were hoisted with all speed, the crew being assisted by twenty fishermen who were on board. This was done only in time to prevent a disaster, for the head of the steamer was got round so close to the Rundle Stone that the buoy marking its proximity was touched.

REPAIRING A BROKEN CRANK WITH WIRE ROPE.

THE following description of the temporary repairs made to the broken cranks of the U.S. steamer *Pensacola* by G. W. Stivers, Passed Assistant Engineer U.S. Navy, is interesting in showing what may be done with wire rope in the way of repairs on shipboard.

The after crank of the forward engine only is shown, this one having been broken entirely across; but the plan adopted in banding both cranks of the after engine, which were broken nearly across, was precisely the same. The crank shaft and cranks were in one solid forging, and the fractures were directly across the bodies of the cranks, between the crank pins and the shaft, as if following the plane of contact of the fagots used in building up the cranks in the smithery.

For several months the existence of a very slight crack in the after crank of the forward engine was known, but frequent examinations failed to show any extension, and it was considered simply a surface flaw of no great consequence.

At about 5 p.m., June 18th, 1880, the ship being on her way from San Francisco to Puget Sound it was found that this crack was rapidly extending. The weather was fine, sea smooth, and with square sails set the engines were slowed down, while preparations were made to strengthen the crank by temporary bands, so as to reach Victoria, were it was expected that a heavy band could be forged and shrunk on. The only iron that could be worked on board ship was a piece 3⅛ in. wide and ¾ in. thick, and it was proposed to make of this two bands, to embrace the crank side by side and to be set up by two 1-in. bolts on each side, passing through lugs formed by bending up and thickening the ends. The strength of the bands as straps was therefore only that of two 1-in. bolts, and its utter insufficiency was evident.

At about 9 o'clock that night the crank had broken entirely across, but as the two parts moved together as usual, the irregular surfaces of the break and the long forward journal preventing their separation, the engines were kept slowly revolving until noon of the next day, when the plan of iron bands was abandoned, before being carried out in favour of the following one, proposed by Mr. Stivers.

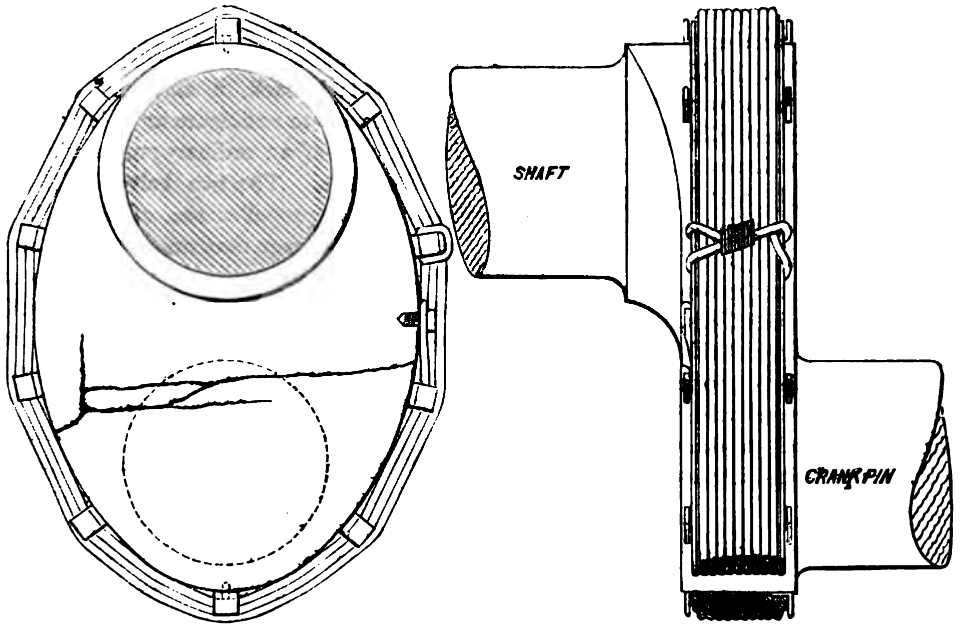
Ten gutter pieces or shoes were made of an old iron grating and placed equidistant about the crank in order to keep the bottom turns of wire rope from spreading apart when the riding turns came to be put on over them. The shoe at the extreme end and that on the butt of the crank only were secured in place by a small bolt through the centre, the other shoes being held in proper position by hand until bound by the first turn or two of rope. Into the hub of the crank a bolt one inch in diameter was tapped, to which the end of the rope was secured, and the work of wrapping the crank consisted simply in passing the wire rope continuously around the crank, hauling each turn taut by means of a heavy deck tackle passing down through the engine room hatch, and seizing each turn securely to the one immediately preceding it before slacking off the tackle. It was estimated that a tightening pull of about two tons was brought on each turn of rope, and the seizing of the separate turns having been done very expertly there was no slacking back of the wire rope during the progress of the whole work.

In this manner eleven turns of the rope were put around the crank side by side, just filling up the space between the jaws of the shoes; then over these were put ten riding turns, and over these again nine riding turns, making altogether thirty turns of wire rope encircling the crank. The finishing end was simply passed around the banding at one of the shoes and stopped, as shown in the sketch.

The wire rope used in this work was of $\frac{9}{16}$ inch diameter, consisting of five strands of 17 wires each, arranged about a central hemp core of inch $\frac{3}{16}$ diameter, the wires being of number 19 wire gauge.

The work of banding this crank was completed in seven hours, and just as it was finished it was found that both the cranks of the after engine were broken nearly across, the cracks extending entirely through each crank to within about one inch of each side, in about the same direction and relative position as in the forward crank. This discovery caused the abandonment of the attempt to reach Victoria; the ship was headed to the southward, with the intention of returning as best we could to San Francisco under sail, and, the banding of the forward crank having been so satisfactorily accomplished, it was decided to strengthen the after cranks in the same manner, so that the engines might be used in case of emergency.

This was done, and when about 200 miles from San Francisco, the wind blowing lightly from ahead, and sails being useless, the engines were started and worked continuously without stopping



REPAIRING A BROKEN CRANK WITH WIRE ROPE.

for over 45 hours, until the anchor was dropped in the harbour of San Francisco. During this time 45,835 revolutions were made, an average of 16·85 revolutions per minute, and an average speed made of 4·41 knots per hour under steam alone. The next day the ship was steamed up to the Mare Island Navy Yard, 26 miles from San Francisco, the engines being stopped and started seventeen times during the run to allow target practice, and upon arrival at the yard the rope banding was found to be as firm and unyielding as when first put on the cranks.

The speed at which the engines were run with these fractured cranks was low, for the weather was fine and no necessity required the taking of the least risk; the initial pressure above zero on the pistons was 20 pounds, cutting off at 9 inches, there being two cylinders, 60 in. diameter and 36 in. stroke; yet it is evident from a calculation of the strength of the banding on the extreme after crank, which transmits the power of both engines, and which would have been further strengthened if more wire rope had been at hand, that a considerably greater speed could have been safely attained.

The gutter pieces or shoes were, it will be seen, indispensable to the successful application of the wire rope banding, for they prevented the first course of rope from spreading under the pressure of the riding turns; they allowed the driving of iron wedges beneath them without injury to the rope, in case it should become slack and require tightening, and they permitted the passing of the end of the rope between the crank and the whole banding so as to secure it firmly.

It was expected that the wire rope would in a short time stretch, and the intention was therefore to first drive iron wedges under each shoe, nipping the ends over the end of the crank, and then to drive all around, under the rope banding, dry pine wedges which would be swelled by the water used on the crank pins, but there was no necessity for any wedging whatever, and perhaps would not have been had the engines been in operation a much longer time than they were. The shape of these cranks made the application of the banding quite a simple matter, though it would not be difficult to adopt such a system of wrapping with wire rope to a crank of any shape whatever.

It is thought that the idea has not occurred to engineers generally that they have in wire rope such a ready and effective means of temporarily repairing damages to engines at sea. Many repairs that are now made with straps or bands hastily constructed under the disadvantages always attending smith's work on board ship can be much more quickly and easily made by a few turns of wire rope. This material may yet be the means of repairing a broken shaft of a steamer so that she will be able to steam into port at a moderate rate of speed.

In the case of repairs to a broken shaft the ends of the rope could be passed through and secured to the back of square pieces fitted into keyways cut in the shaft, then passing the rope around the broken shaft and securing the other end of the rope in a like manner; these pieces to be bolted to the shaft with tap bolts; for backing the rope must be wound around the shaft in the opposite direction.

The ease and facility with which repairs can be made with wire rope commend it to engineers and steamship owners as a part of the necessary outfit for a steamship. J. C. Kafer.

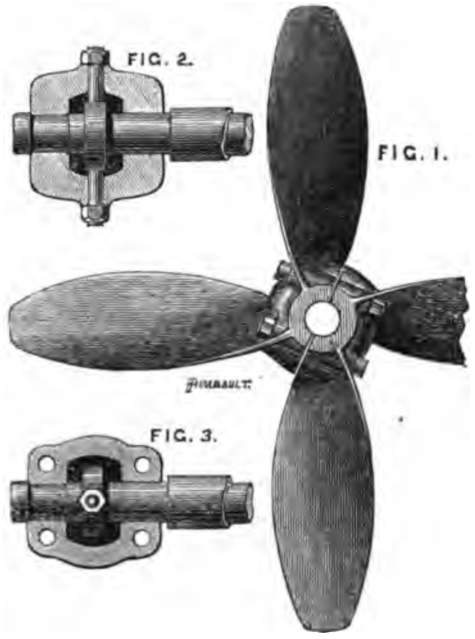
The Palmer Shipbuilding and Iron Company, at Jarrow, are now laying down the first of two very large iron screw steamers for Messrs. Leyland, of Liverpool. The steamers will measure 430 ft. in length by 40½ ft. in breadth and 20½ ft. in depth. They will be the largest vessels ever built in the Tyne.

Naval Exhibition.—The Shipwrights' Company have issued a public invitation to the ingenious of all nations to contribute to a competitive exhibition to be held in Fishmongers' Hall, in June, 1882, of models and designs of every sort of floating craft, from fishing smacks and torpedo launches to clipper-built schooners and stately vessels of war.

Mr. Robert Harrowing, of the firm of Messrs. Robert Harrowing & Co., steamship owners, Whitby, has contracted with Messrs. John Redhead & Co., of South Shields, for the construction of four large steamers of 2,100 tons each deadweight carrying capacity, which will be ready to take their places in Messrs. Harrowing & Co.'s large fleet by the commencement of 1882.

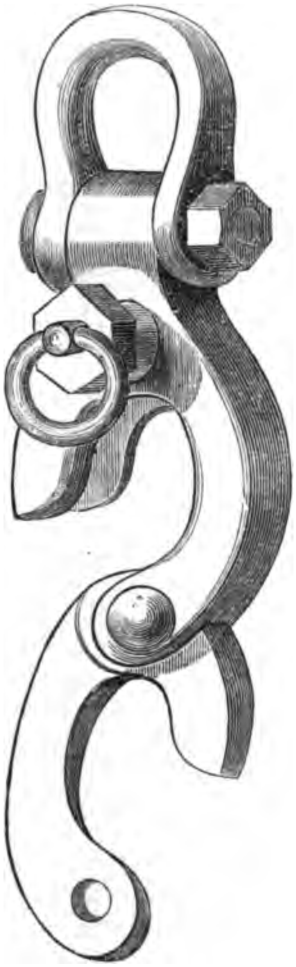
COOKE & MYLCHREEST'S SPLIT BOSS SCREW PROPELLER.

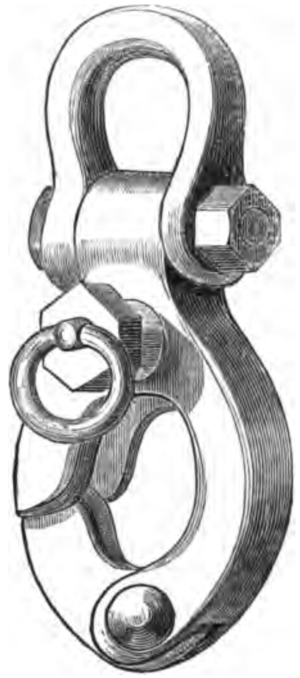
We subjoin an illustration ot the "split boss" screw propeller lately patented by Messrs. Cooke and Mylchreest. The invention is a very simple one, and considering the convenience attending it, it is singular that it should not have been introduced earlier. The essential feature consists simply in making the propeller in two halves, which are bolted together so as to clip the shaft. Referring to the engravings it will be seen that in the propeller, shown by Fig. 1, the two parts are simply held together by four bolts, while Figs. 2 and 3 show a modified arrangement specially suitable for propellers of large size. In the case of large propellers it would be inconvenient that both halves should be set free from the shaft together on removal of the connecting bolts, and to get over this a ring bolt A is provided, in addition to the four main bolts already mentioned. The centre part of this ring bolt is a good fit on the shaft, but is not keyed to the latter or fixed in any way, while the ends are each screwed for a nut. It will be seen that, by means of this ring bolt, the two parts of the propeller will be held on the shaft after the main bolts have been removed, and each part can be taken off separately at pleasure. There is, of course, no occasion to make the shaft tapered where it fits the screw, but it is collared at the end, and this prevents the screw from working back or off the shaft. In a propeller 14 feet 6 inches in diameter, with four blades, which the patentees have recently fitted to the new steamer, *Aristides* (2,300 tons), they have produced four main bolts, 4¾ inches in diameter, and a ring bolt with end, 3½ inches in diameter, so that a very strong connection is obtained, the intention being to provide a connection with a strength materially in excess of that of the propeller itself at the roots of the blades. As regards any tendency of the nuts to slack back, it may be said that there is no more reason to anticipate trouble from this cause than in the case of an ordinary propeller with blades bolted to the boss. The two halves of Messrs. Cooke & Mylchreest's propeller are, of course, much more convenient for stowage than an ordinary spare propeller, and altogether the arrangement promises to be a very useful one. Its chief advantages may be briefly summed up as follows:—Increased facilities in overhauling the propeller when needful, and a corresponding decrease of expenses, dock charges, and last, but not least, the great reduction of time in detention of the vessel; small space for stowage of spare propeller, it being in halves. Again, the castings are, for the same reason, much sounder than when cast whole, and the actual cost of manufacture of the propeller is considerably less than when cast whole. The royalty for the use of this patent is charged on each vessel using it, and not on the propeller itself, so that a steamer once licensed, no future charge is made for additional screw propellers supplied. Mr. John Hayes, of 27, Leadenhall Street, E.C., is introducing this propeller, and at the present time he has some large propellers in hand for steamers at Barrow, Sunderland, Cardiff, and other ports, and although, like most new improvements, it is being taken up somewhat cautiously by the shipping interest, still we think we are not far wrong when we say that it is decidedly a step in the right direction.



MORRIS & BENNETT'S PATENT SAFETY BOAT-LOWERING APPARATUS.

In our April issue we described and illustrated a boat-lowering contrivance, the property of the British and Foreign Boat-Lowering Company, Limited; and as every invention of a practical nature, bearing upon the important subject of saving life at sea cannot be brought forward too prominently in order that ship-owners may have every opportunity afforded them of being well-informed on this head, we have now pleasure in noticing the invention of Messrs. Conway, Morris & Bennett, Engineers, &c., 175, Blackfriars Road, London. We should state that the illustrations given refer to only one of *several* applications of a series of British and Foreign Patents taken out by the Firm named, for useful and ingenious disengaging, releasing, and "slipping" contrivances. It is only our province, however, to deal with that particular application which is of *direct* interest to our readers, as shown in the accompanying wood-cuts; viz., for lowering boats; Fig. 1 showing the "slip," disengaged or open, and Fig. 2 showing it shut. Its construction and action are as follows:—





The frame of the "slip" consists, as shown, of two sides or members, one of which is shorter than the other; the shorter side being slotted right through, and the longer side is recessed. The moveable or locking part is pivotted as shown, at the end of the longer side of the framing. It will be noticed that the end of the locking or moveable part of the "slip" is formed with an eye, which, on the "slip" being locked, takes into a spring locking and unlocking bolt or pin, with ring-releasing attachment at the head of the "slip" as shown, and which, when locked, will bear with safety a very considerable weight or strain upon it, while, on the other hand, on pulling the spring bolt, the weight or strain is immediately released. To facilitate the instantaneous action of the apparatus, the centre of the pivot at the lower end is slightly out of the line of the centre of the releasing spring pin or bolt. In applying the invention for boat-lowering, a pair of such "slips" are employed, and which may either be attached to the falls of the davits, or they may be fixed to the boat itself fore and aft, and, by means of a simple lever arrangement, a simultaneous release is effected.

Some experiments recently conducted in the East India Docks, at the request of Messrs. Shaw, Savill, & Co., resulted in showing the extreme simplicity and reliability of the contrivance, even when applied under considerable disadvantages as regards the existing tackle.

Messrs. Morris & Bennett's apparatus is *not*, it will be noticed, *automatic* in its action; and, though we are aware an automatic system of boat lowering has been recommended in certain quarters, we believe that, on due consideration, it will be found there are some fatal objections to be urged against its adoption. We may instance the liability of a boat to be released *before* it has been occupied, in the case of disaster, by the action of the waves in a heavy sea. Whereas, by the invention under notice the boat may be released at any desired moment with perfect safety, and by a simultaneous "slip."

ON STRENGTH OF CRANK SHAFTS.

BY J. T. MILTON, ESQ., Assistant Chief Engineer, Surveyor to Lloyd's Register; Member.*

AT the meetings of this Institution in 1879 I had the honour to read a Paper "On Some of the Causes of the Failure of Crank Shafts," in which it was shown that the bending moment produces a very considerable portion of the strain on crank shafts, even when all the bearings are in line; whilst if the bearings are allowed to get out of line the bending moment produces a very considerable increase of strain, a strain, in fact, very much greater than that due to the twisting moment. This was illustrated by a series of curves showing for five different types of engines the strains on each bearing for any position of the cranks, both when the bearings were lineable and also when one or other of the bearings was removed, a condition which I pointed out as being equivalent to the limit of unlineability likely to take place, and one which is by no means unlikely to occur in practice every time a bearing is allowed to become heated.

These diagrams showed that, with the engine in good working order, the second and third journals from forward have each to transmit the twisting moment of the forward engine, and have also to withstand a small bending moment; the fourth journal has to transmit the combined twisting moment of the two engines, whilst the after crank-pin has to bear a considerable bending moment in addition to a twisting moment, and is therefore in general the most strained part of the shaft.

When one of the centre bearings is taken away, the greatest strain comes upon the adjacent crank-pin, but the greatest strains coming on the shaft are produced on the second bearing when the first is slacked back, and on the third bearing when the fourth is slacked back.

Thus in engine B, in which the cranks are at 90°, it is seen that with the second bearing slack the strain on the shaft becomes increased to 1·57 times its original amount, while with the first bearing slacked, the strain is increased 2·29 times. In engine C, with cranks also at 90°, the increase of strain is 1·60 and 2·24 times in the two cases, but in engine D, with cranks at 130°, the increase is not so marked, it being only 1·11 and 1·53.

In the present paper I wish to lay before you the effect produced on the strains on the shafting by variations in the angles between the cranks, and also by a variation in the length of the stroke.

For this purpose I have taken the indicator diagrams of a pair of engines with cylinders of 30 and 60 inches diameter and 39 inches stroke, worked at a boiler pressure of 85 lbs. per square inch. They are of recent construction, and are a very well-designed and efficient pair of engines. From the diagrams the crank pin pressures have been ascertained, allowance being made for the effect of the inertia and weight of the reciprocating parts, and the strains on the shafting have been calculated for every 20° of the revolutions of the engines in ten cases, the angles between the cranks varying from 90° to 180°. The results of the maximum strains are given in Table I. The similar strains occurring in the engine on the supposition of the stroke being increased to 60 inches have also been calculated, and the results are given in Table II. The twisting moment is increased proportionately to the length of stroke, but the bending moment remains unaltered. In each case I have calculated the amount of the increased strain due to slacking back the bearing as well as the strains caused by the ordinary working, in the same manner as was done in the previous paper, as it is important in designing any structure to provide for any abnormal strain likely to come upon it as well as for the strains due to ordinary working.

In Fig. 1 are seen the twisting moments on the supposition of the cranks being set at the various angles from 90° to 180°; the dotted line represents the mean twisting moment, and the upper black line the combined moment at the different parts of the revolution. From these diagrams it is seen that the least twisting strain comes when the angles of the crank are at 90°; gradually increasing with the increase of the angle between the cranks until at 180° it reaches its maximum of 35 per cent. in excess of that at 90°. It is to be remarked that the ratio of the maximum moment to the mean, viz., $\frac{1\cdot31}{1}$ in this engine, even when the cranks are at 90°, is much greater than it is usually thought to be, and in a large number of cases, when the inertia and the obliquity of the connecting rod are taken into account, I have rarely found the r fall below $\frac{25\cdot}{1}$

In Fig. 2 will be seen representations of the bending and ing moments on the after crank-pin which is the part of th most strained, they being represented by black lines, wh upper dotted line represents the stress caused by the twisti bending combined. From these diagrams it is seen that th on the crank shaft, unlike the twisting moment alone, is l this engine with the cranks at angles of 110°, while it is th at 140° as at 90°, and then increases as the angle increases, t but the increase is not nearly so great as in the case of the tw moment, being only 13 per cent. as compared with 35 per and comparing the strain on the crank-pin with that on shafting, we find that only at 90° and 100° is it much grea all the other angles the difference not exceeding 5 per cent.

Fig. 3 shows the strains on the second bearing on the supp of the first being slacked back. In this case the strain is pra the same for all angles of the crank.

Fig. 4 shows the strains coming on the third bearing wh fourth bearing is slacked back. From these diagrams it i that the greatest strain occurs in the case in which the cran at 90°, and the least when they are at from 150° to 180°; s In this case, which is practically the worst that can befall th those engines with cranks at larger angles have a decided adv over the one with cranks at 90°, especially if we compare th thus produced with the greatest strain coming on the crank s ordinary working, as shown in Fig. 2.

Taking now the case of the engine with the stroke increase 39 to 60 inches, the crank pin pressures remaining the sa find these results a little modified.

The twisting moments will still be represented by Fig. 1, l scale will be altered, and the ratio of maximum to mean tw moment will therefore be the same.

The strain on the aft crank pin is shown in Fig. 5, the low again representing the bending moment, and the dotted li stress caused by the twisting and bending combined. It w seen by comparison with Fig. 2 that this is much less in prop to the twisting moment than in the case of the shorter stro fact, it is only in the case of the engine with cranks at 90°, th strain on the aft pin exceeds that borne by the screw shaftin

In Fig. 6 is shown the strain on the second bearing c supposition that the first is taken away and as with Fig. 3 case of the short-stroke engine, this is practically the same at ever angle the cranks are inclined.

In Fig. 7 is shown the strains coming upon the third b when the fourth is slack, and, as in the case of the other e these are absolutely more when the cranks are at 90° than they are wider apart.

STRAINS ON CRANK SHAFTS.

Fig. 4.

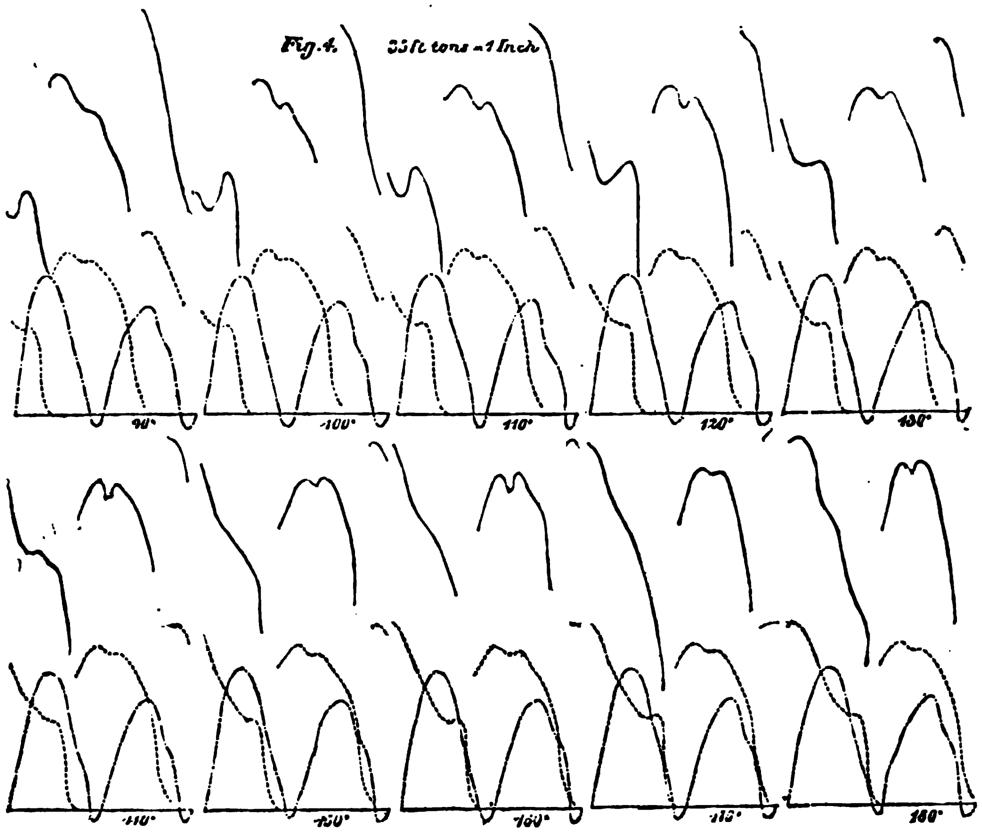

Fig. 7.

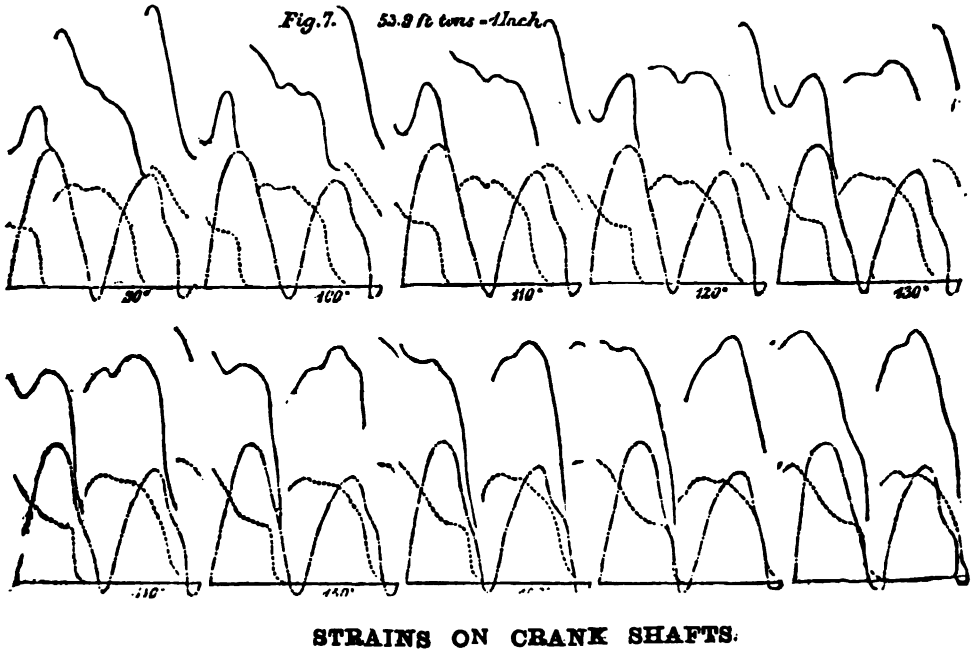

STRAINS ON CRANK SHAFTS.

From these diagrams it is seen that the extra strain thrown on the crank shaft by increasing the angle of the cranks beyond 90° is not so great proportionately as that thrown on the screw shafting, whilst the extra or undue strains thrown upon the crank shaft by any unlineability of the bearings is less in the engines with the cranks wide apart than in that with the cranks at 90°.

These diagrams also show very conclusively that in engines in which the strokes bear different proportions to the diameters of the cylinders, it is wrong to assume that the straining effect on the shafts varies as the twisting moment, it being seen in these two cases (*vide* Table III.), that with the same useful work done in the engine with the longer stroke, the crank shaft is only strained about nine-tenths as much as in the short-stroke engine, while in the extreme cases of the shaft being unevenly supported at the bearings, this proportion becomes still less.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of the* MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Heron.—On April 16th Messrs. Scott & Co. launched from their building yard a handsomely-modelled iron screw-steamer, of 150 tons, built to the order of Messrs. R. Walker & Co., Clyde Terrace, Glasgow, and intended for the Loch Fyne herring trade. She will be fitted with compound surface-condensing engines of 45-horse power, by Messrs. R. Harvey & Co., Glasgow. As the vessel moved into the water she was named *Heron* by Mrs. Gibb, Granby Terrace, Glasgow.

Galileo.—On April 26th there was launched from Messrs. Earle's yard, Hull, a steamship for Messrs. Thomas Wilson, Sons, & Company, of Hull. As the vessel left the ways she was named the *Galileo*. She is the 61st ship built for Messrs. Wilson by Earle's Company, is intended to form an addition to the line of the Atlantic steamers, and is designed for the conveyance of cargo and cattle, the accommodation for which is very complete, the whole of the 'tween decks, a long turtle back forward and aft, and the bridge amidships being devoted to this purpose. The vessel will by this means be enabled to bring over an unusually large number of cattle, and will also carry 4,000 tons dead-weight. The accommodation for captain, officers, and a few passengers is provided under the bridge, the crew being berthed forward, under the upper deck. The vessel is built on the longitudinal system adopted in the ships of her Majesty's Navy, having a complete inner bottom, extending fore and aft. This feature gives additional safety in the event of striking the ground, as well as providing for water ballast, the arrangements for filling and discharging the ballast being of a very complete description. The length between perpendiculars is 350 ft.; her breadth, 41 ft.; and depth in hold, 27 ft. 6 in. She is brig rigged, and is built to class 20 years in the Liverpool Registry. She has long shelter decks at each end and amidships for the purpose of carrying and sheltering cattle on the upper deck, in addition to the usual accommodation between decks. The gross tonnage of the vessel is 3,500 tons. She is propelled by a pair of compound surface-condensing engines of 300 nominal horse power, the cylinders being 34 in. and 68 in. diameter by 63 in. stroke, and very similar in general design to those of the screw steamship *Romano.*

Oliveto.—On April 26th there was launched from Mr. Laing's yard at Deptford, an iron screw-steamer of the following dimensions:—Length over all, 300 ft.; breadth, 36 ft.; depth to awning deck, 27 ft. She will be fitted with Emerson & Walker's direct steam windlass, Higginson's "steam quartermaster," Clark, Chapman, & Gurney's steam winches, Colling & Pinkney's topsails, and engines of 180-horse power by Mr. George Clark, Southwick. This is the eleventh steamer built by Mr. Laing to the order of Messrs. G. D. Pinkney & Sons, and she is fitted with all the latest improvements in outfit, and is intended for the South American and Indian trades. As she left the ways she was christened the *Oliveto* by Miss F. Alcock, daughter of Mr. J. T. Alcock, J.P., of Newcastle.

Blaenavon.—On April 26th a screw-steamer was launched from Messrs. Palmer & Co.'s Howdon shipyard. This is the first vessel launched from this yard since its re-opening, and is of the following dimensions, viz.:—Length, 240 ft.; breadth of beam, 33 ft.; depth of hold, 16 ft. 6 in.; and is to be fitted up in the usual manner, with steam winches, windlasses, &c. She is classed 100 A 1 at Lloyd's, and has been built to the order of Morrell Brothers, Cardiff, and under the superintendence of Captain P. Gills, Cardiff. As she glided from the stocks she was named *Blaenavon*, by Miss Price, daughter of the general manager of Palmer & Co.'s shipyards. The *Blaenavon* is intended for the Bilbao trade.

Hermann.—On April 28th the Sunderland Shipbuilding Company (Limited) launched from their yard at the South Dock an iron screw-steamer of the following dimensions:—Length over all, 330 ft.; breadth, 40 ft.; depth to awning deck, 29 ft. 3 in. and is expected to carry 3,800 tons deadweight. She is classed 100 A 1 at Lloyd's, and has iron 'tween decks and wooden upper deck, water ballast, five bulkheads, four steam winches, Emerson & Walker's direct-acting steam windlass, Colling & Pinkney's topsails, Higginson's "steam quarter-master," and all other recent improvements. She has been built to the order of Messrs. D. G. Pinkney & Sons, but sold by them to some friends on the Continent, and will form one of the White Star Line of Steamers from Antwerp to New York, carrying emigrants and general cargo. The ceremony of naming the vessel the *Hermann* was performed by Miss Marion Pinkney, daughter of Mr. D. G. Pinkney.

Balaklava.—On April 28th Messrs. Osbourne, Graham, & Co. launched from their yard at Hylton an iron barque, built to the order of Messrs. Davison, Bisset, & Co., of Liverpool, of the following dimensions and particulars:—220-horse power, by 36 ft. 6 in. beam, by 22 ft. 6 in. deep; built with short full poop aft, containing accommodation for Captain and Officers and a few passengers: teak house amidships with galley and accommodation for petty officers and crew. The vessel will be classed 100 A1 at Lloyd's, and has been superintended during construction by Captain James Davison, who will command her. On leaving the ways the vessel was named the *Balaklava* by Mrs. Jas. Davison.

Ross-shire.—On April 30th Messrs. Edward Withy & Co. launched from Middleton shipyard, West Hartlepool, an iron screw steamer, built to the order of Messrs. Turnbull, Martin, & Co., of Glasgow, and under the inspection of Mr. J. Wotherspoon, of Port Glasgow. Her principal dimensions are:—Length, b.p., 285 ft.; beam, extreme, 36 ft.; depth moulded, 25 ft. 2 in. She is built to Lloyd's highest class as a three-decked cargo-boat, and has top-gallant forecastle and long bridge-house protecting the stokehole openings, three masts, the fore and main being of iron, four steam winches, and steam steering gear. Her main deck is of iron throughout, and she is constructed on the cellular double-bottom principle. She will be fitted with compound engines, working at 80 lbs pressure, by Messrs. Blair & Co. (Limited), of Stockton-on-Tees. The cylinders will be 34½ and 64 by 42 stroke. She is intended to be employed mostly in the general freight trade, and will carry 3,000 tons deadweight. As the steamer left the ways she was christened *Ross-shire* by Miss Marion Withy.

Dryburgh Abbey.—On April 30th there was launched from Messrs. Wigham Richardson's & Co.'s Neptune Works on the Tyne, a screw steamer, of 3,500 tons burthen; and as she left her berth she was christened the *Dryburgh Abbey*, by Miss Purves of Newhouse, Dunbar, This steamer has been specially designed for the Atlantic and Indian trades, and in her construction attention has been paid to her increasing requirement for the safe conveyance of live stock from America. Her dimensions are—300 ft. by 37 ft. by 27½ ft., and she will be fitted with engines, by her builders, of 1300 effective horse power. The boilers, three in number, embrace all the latest improvements for the consumption of any kind of coal. She has been built to the order of Messrs. Wood Brothers & Co., Liverpool, under the superintendence of Messrs. Ashlin & Asbridge, Liverpool, and will be commanded by Captain Forbes.

Moss Rose.—On April 30th there was launched from Messrs. Edward Finch & Co.'s (Limited) shipbuilding yard, at Chepstow, an iron screw tug steamer for Messrs. D. Guy & Sons, of the Bute Docks, Cardiff, of the following dimensions:—Length, 80 ft.; breadth, 15 ft. 6 in.; depth, 9 ft.; to be fitted with compound surface-condensing engines of 45 nominal-horse power, and to have a Board of Trade certificate for passengers. The vessel will have two cabins, fitted fore and aft with lifeboat, &c., for excursion purposes. She was christened the *Moss Rose* by Miss Ada May Guy, granddaughter of the senior partner of the Owner's firm.

Chateau Lafite.—On April 30th there was launched from the shipbuilding and engineering establishment of Messrs. Oswald, Mordaunt, & Co., at Southampton, a screw steamer for the Bordelaise Company, of Bordeaux, of which M. Lalande is president. The ceremony of naming the steamer was performed by Madame H. Bordet, of Bordeaux, and the steamer was named the *Chateau Lafite*. She will be under the command of Captain Billard. This steamer, which will take the highest class at Lloyd's, and is built in excess of their requirements for the class, is intended to run between Bordeaux and New York, and is the pioneer steamer of the company's fleet. Her dimensions are:—Length, 380 ft.; breadth, 41 ft. 6 in.; depth of hold to upper deck, 30 ft.; gross tonnage, about 3,800 tons. She has a forecastle and a bridge amidships; she has a saloon fitted up to accomodate 40 first-class passengers. Her engines, also by the same builders, are of the direct-acting compound inverted cylinder type, and are expected to indicate 2,400-horse power. The vessel is also fitted with steam steering gear amidships, steam windlass for lifting anchors, steam winches and cranes for rapid discharge of cargo, and all other modern improvements, She is expected to be ready for sea by the end of June next.

On May 11th, there was launched from the shipbuilding yard of Mr. George K. Smith, Newcastle-on-Tyne, a small screw steamer of the following dimensions:—Length, 52 ft., breadth, 11 ft., depth 6 ft. 6 in. This vessel was built to the order of Messrs. Dobeson & Wost, engineers, &c., Gateshead, where she was taken to receive her engines, and will afterwards be employed for towing.

On May 12th there was launched from the shipbuilding yard of Mr. George R. Smith, of Whitehill Point, North Shields, a small iron screw steamer of the following dimensions:—Length, 52 ft.; breadth, 11 ft.; depth, 6 ft. 6 in. She was built to the order of Messrs. Dobeson & Sons, Team Engine Works, where she is to receive her engines.

Muriel.—On May 12th Messrs. Hodgson & Soulsby launched from their building yard, at Blyth, an iron screw steamer named the *Muriel*, built to the order of Messrs. Sanders & Son, merchants, Colchester. Her dimensions are:—95 ft. long, 18 ft. 3 in. beam, and 7 ft. 6 in. depth. The steamer will be classed 90 A 1 at Lloyd's; she has an iron deck and water ballast, hatchway 30 ft. by 11 ft., and combings 2 ft. 3 in. high, with large hold for light goods. The dead weight cargo will be 140 tons on about 7 ft. She will have a powerful horizontal steam winch for working cargo, and also for working windlass for getting anchors, and will steer from a bridge in midships. She has been designed by R. Shead, Hythe Quay, Colchester, and he intends to run her between London, Colchester, and Mistley. She has compound engines by R. & W. Hawthorne, of Newcastle, and will be ready by the end of May.

Combermere.—On May 14th an iron sailing ship was launched from the building-yard of Messrs. Richardson, Duck & Co., South Stockton-on-Tees, of the following dimensions, viz.:—Length over all, 264 ft.; length between perpendiculars, 244 ft.; extreme breadth, 39 ft.; depth in hold, 24 ft. 3 in.; gross tonnage, about 1,724 tons; nett tonnage, 1,667 tons. She is classed 100 A 1 at Lloyd's and 20 years Liverpool, and has been built under special survey. The vessel has a full poop, for the accommodation of first-class passengers, Captain and Officers; a topgallant forecastle, and a deckhouse amidships for the crew, galley, &c. The ship has been built to the order of Messrs. C. W. Kellock & Co., Liverpool, under the inspection of Captain Cranston and Mr. Malcolm. As the vessel was leaving the ways she was christened the *Combermere* by Miss A. C. Richardson, of Newcastle-on-Tyne.

Akaba.—On May 14th, Messrs. M. Pearse & Co. launched from their iron shipbuilding yard, at Stockton-on-Tees, an iron screw steamer of the following dimensions:—Length between perpendiculars, 300 ft.; extreme breadth, 36 ft.; depth of hold to top of floors, 25 ft. 6 in. She will be about 2,300 tons gross register, and will class 100 A 1 at Lloyd's. She has full poop, long bridge, and topgallant forecastle, and is built on the three-decked rule with two decks laid, both being of iron, and will be rigged as a three-masted schooner, having double topsails on her foremast. She will be fitted with engines by Messrs. Blair & Co., of 280-horse power nominal, and have four steam winches and patent steam steering gear. She has double bottom for water ballast, and all the most recent and improved appliances for expeditiously loading and discharging. As she left the ways she was christened *Akaba* by Miss Florence Fowler,

Columbia.—On May 14th Messrs. W. H. Potter & Son launched from their shipbuilding and engineering works, Queen's Dock, Liverpool, a new iron sailing vessel of the following dimensions, viz.:—Length, 279 ft.; beam, 39 ft.; depth in hold, 24 ft.; tonnage, B.M., 2,000 tons. The vessel was christened the *Columbia* by Mrs. Sandbach Parker. The *Columbia* has been built to the order of Messrs. Sandbach, Tinnie & Co., of Liverpool. She will receive Lloyd's and Liverpool Underwriters' highest class, but her scantling is considerably in excess of the requirements of both books. The *Columbia* will shortly be placed on the loading berth for Calcutta, and will be commanded by Captain W. H. Angel, formerly of the *Sheila*.

Macedonia.—On May 14th Messrs. William Gray & Co., launched from their yard at West Hartlepool, an iron screw steamer of the following dimensions:—Length, 256 ft. 6 in.; breadth, 34 ft. 6 in.; depth in hold, 19 ft. 8 in., to the order of William Gray, Esq., West Hartlepool. This vessel is intended for the American, Mediterranean, or Indian trades, is 1,750 tons register, and fitted with engines of 140-horse power, constructed by Messrs. Blair & Co., (Limited), Stockton; she has also four steam winches by Clark, Chapman & Co., and patent windlass by Emerson & Walker. On leaving the ways the ceremony of christening was performed by Mrs. Gray, and the vessel named *Macedonia*.

Anjer Head.—On May 14th, Mrs. Raylton, Dixon & Co. launched from their Cleveland Dockyard, Middlesbrough, the above-named steamer. The christening ceremony was performed by Miss Mary Lennard, daughter of J. M. Lennard, Esq., of Middlesbrough. The *Anjer Head* is 286 ft. long over all, 36 ft. broad, and 24½ ft. in depth, and will carry about 2,900 tons deadweight, or 3,500 tons measurement. Her engines, by Messrs. T. Richardson & Sons, of Hartlepool, are expected to develope about 1,200-horse power effective. All the arrangements of the steamer for working cargo are most complete, and her outfit comprises all the newest improvements.

Harvest.—On May 14th an iron screw steamer, built to the order of Messrs. English, Smurthwaite & Co., of West Hartlepool, was launched from Messrs. Irvine & Co.'s shipyard. Her dimensions are as follows:—245 ft. in length, 33 ft. in breadth, and 17 ft. 9 in. depth of hold. She is constructed to carry 2,000 tons deadweight. She is built on the cellular bottom principle, and is fitted with three steam winches and other appliances suitable for the general trade. The engines, of 130-horse power, will be supplied by Messrs. Thomas Richardson & Son, of Middleton Iron Works. As she left the ways the vessel was christened the *Harvest* by Miss English.

Talabot.—On May 14th Messrs. Schlesinger, Davis & Co. launched from their building-yard at Wallsend an Iron screw steamer, named *Talabot*, for La Société Française des Steamers de l'Ouest, Mesnier & Co., of Havre and Swansea. This vessel, which measures as follows—245 ft. between perpendiculars, 33 ft. broad, and 16½ ft. depth of hold—classes 100 A 1 at Lloyd's, has been built under the special inspection of Lloyd's and the owner's surveyors, and will carry large cargoes on a light draught of water. Being intended principally for the coal trade, she is constructed with Price's self-trimming hatches for saving both time and expense in loading. She will be fitted with steam windlass, Harrison's patent steam steering gear; steam winches at each hatch, and every requisite on deck. The cabins are amidships, and will be fitted with every convenience. The engines are being constructed by Messrs. R. & W. Hawthorn, of Newcastle, and the cylinders are 38 in. and 58 in. diameter, with a stroke of piston in both of 36 in. The christening ceremony was performed by Miss Ida Davis.

Ethel Horatio.—On May 16th Messrs. Osbourne, Graham, & Co. launched from their yard at Hylton an iron screw steamer, built to the order of a local firm, the third by the builders for the same firm. The dimensions of the vessel are 225 ft. long, 32½ ft. beam, and 16 ft. 6 in. deep, and she is built with long raised quarter deck, bridge house, and topgallant forecastle, large hatches of the "Step" pattern, and will be fitted with three steam winches and all facilities for rapid loading and discharging, and compound engines by Messrs. Hawks, Crawshay & Sons, of Gateshead, with cylinders 28 in. and 54 in. and 36 in. stroke. On leaving the ways she was named the *Ethel Horatio*, by Mrs. J. F. Marshall.

Kent.—There was launched on May 16th, from the Wear Dockyard, Sunderland, by Messrs. S. P. Austin & Son, an iron screw steamer, named the *Kent*, of about 1,020 tons gross register, specially designed for the ore and coal trades to carry a large cargo, on light draught of water, at a high rate of speed. She has been built under special survey to class 100 A 1 at Lloyd's, and will be completed in detail similar to the *Medway*, constructed at the same establishment for the same owners, Messrs. Lambert Bros, London.

Darien (s).—On May 17th a screw steamer, built to the order of Messrs. Nelson, Donkin, & Co., of Newcastle, was launched from the Jarrow Yard of Messrs. Palmer & Co. Her dimensions are:—Length, 328 ft.; breadth of beam, 39 ft.; depth of hold, 26 ft. 9 in. She will have three decks, two of which will be of iron, and will be fitted with water ballast in the bottom and in a deep tank, which can also serve for cargo in the hold. She will be rigged as a three-masted schooner, and her carrying capacity will be 3,600 tons deadweight. She is intended for general trade, and is named the *Darien*.

Acacia (s).—On May 17th Messrs. Short Bros. launched from their Pallion Yard, Sunderland, a steamer, to the order of Messrs, Coatsworth, Stockdale, & Co., Sunderland. Dimensions:—Length over all, 270 ft.; breadth, 36 ft.; depth, 19 ft. 6 in.; with engines of 180-horse power, by Mr. John Dickenson. As she left the ways she was named the *Acacia* by Mrs. Stockdale.

Pelham.—On May 18th a steamer, named the *Pelham*, was launched from the shipbuilding-yard of Messrs. Hodgson & Soulsby, Cowpen Quay, Blyth. The steamer, which is fitted with all modern improvements, is intended for the coasting trade, having been specially built to the order of a firm of merchants in Newcastle.

LAUNCHES.—Scotch.

Carmona.—On April 28th, in presence of a very large crowd, Messrs. Gourlay Brothers & Company launched the largest vessel ever built at Dundee. She is to the order of Messrs. W. Thomson and others, and will be commanded by Capt. Halcrow, presently of the *Avlona*, belonging to the same owners. She is an iron screw-steamer, registering 3,800 tons gross, and her dimensions are:—Length, 350 ft.; breadth moulded, 42 ft. 6 in.; depth of hold, 33 ft. 6 in. Her class is 100 A in Lloyd's Register. Among the prominent features in construction are the following:—She has three iron decks, three holds, and five watertight bulkheads. Besides, she is provided with a double bottom on the Bracket system; the space between the two bottoms being used as water ballast tanks. A turtle or whale's back to protect the vessel in a seaway is built over the forecastle, and there is a house aft covering the steering gear. Steam steering appliances are situated amidships in addition to hand steering gear aft. For lifting the anchor Emerson & Walker's steam windlass is introduced. The vessel will be rigged as a three-masted schooner, and will carry five boats. She will be fitted with compound surface-condensing engines of 380-horse power nominal. The high pressure cylinder is 42 in. in diameter, and the low pressure is 80 in., while the length of stroke is 54 in. Steam is generated by two boilers, each fired from both ends. The propeller blades are movable, so that if one is broken a new one can be easily screwed on in its place. There are four steam winches for working cargo, steam for which is supplied by either the donkey or main boilers. She is intended to run in the cattle trade between North America and the United Kingdom, and will accommodate on her three decks 750 to 800 head, besides carrying fully 12,000 quarters of grain in her holds. Very complete arrangements have been made for the thorough ventilation of the ship. There is ample accommodation for the crew, the officers' berths and saloons being at the after end of the main deck, and the seamen's berths in the forecastle. In addition there is suitable accommodation for the cattlemen. The launch was singularly successful, and as the vessel left the ways she was gracefully christened the *Carmona* by Mrs. Moncur, wife of Mr. A. H. Moncur, one of the owners. When the magnificent ship took the water loud cheers were raised by the spectators.

Krete.—On April 28th Messrs. H. M'Intyre & Co. launched from their building yard at Merksworth, Paisley, an iron screw-steamer named the *Krete*, which has been built to the order of Cavalero D. P. Gudi, Naples. The steamer, which has been built under the superintendence of Capt. N. G. Gudi, her future commander, is intended for passenger and goods traffic in the Archipelago. She is built to the highest class at Lloyd's, and her cargo and other appliances are of the most modern description. The makers of the engines are Messrs. Hutson & Corbett, Glasgow. The ceremony of naming was performed by Miss Mary Orr, Hillhead, Glasgow.

Vesta.—On April 30th there was launched from the shipbuilding-yard of Messrs. Scott & Co., Cartsdyke, Greenock, an iron-screw steamer, of 3,400 tons and 400-h.p., built to the order of Messrs. Rathbone Brothers & Co., Liverpool, for the Star Navigation Company. The dimensions of the steamer are as follow:—Length, 365 ft.; breadth, 39 ft.; and depth, 28 ft. 7 in. As she left the ways the vessel was named the *Vesta*.

Carnarvonshire.—On April 30th, the London and Glasgow Shipbuilding Company (Limited), launched at Govan, for Messrs. Jenkins & Co., of London, an iron screw steamer, of about 2,500 tons gross register, her dimensions being—Length, 330 ft.; breadth, 35 ft. 6 in.; depth, 25 ft. 8 in., and built to Lloyd's highest class for three-deck vessels. This steamer, which will be fitted by her builders with compound surface condensing engines, of 350 nominal horse power, of the most approved type, and combining all the latest improvements, steam-steering gear, &c., will form one of Messrs. Jenkins & Co.'s well-known "Shire" Line, trading between London and Japan. As the vessel left the ways she was named *Carnarvonshire* by Miss Campbell, daughter of Bailie Campbell, Govan.

Iolanthe.—On April 30th an iron steam yacht, named the *Iolanthe*, was launched from Messrs. Ramage & Ferguson's shipbuilding-yard at Leith. By yacht measurement the tonnage is 620 tons, and her dimensions are:—Length, over all, 205 ft., length, keel, and forerake, 185 ft., breadth, 27 ft., and depth, 16 ft., moulded. Every recent improvement in yacht construction has been introduced. The engines, which are of 110-horse power nominal, are being supplied by Messrs. Matthew Paul & Co., Dumbarton, and have cylinder 27 in. and 50 in. diameter, by 30 in. stroke, and a speed of about 13½ knots per hour is expected to be obtained. The *Iolanthe* has been built to the order of T. J. Waller, Esq., London, and has been specially designed for long foreign cruises. On leaving the ways the ceremony of naming her was performed by Miss Waller, eldest daughter of the owner.

Aranmore.—On April 30th a new screw steamer of 1,100 tons, built and engined by Messrs. W. Simons & Co., was launched complete from their works at Renfrew. She is the property of the Clyde Shipping Company, and is the seventh steamer constructed for them by this firm. She is named *Aranmore*, and is intended for the Channel trade, having cabin accommodation. This steamer is fitted with compound engines and steel boilers of 700-horse power, and is also fitted with steam appliances for loading, mooring, steering, ventilating, and discharging, and has the highest class at Lloyd's and the Board of Trade.

Hebridean.—On April 30th Messrs. Thomas B. Seath & Co., Shipbuilders, Rutherglen, launched from their yard an iron screw steamer of 350 tons burthen, and of the following dimensions:—140 ft. long, 23 ft. 6 in. beam, and 12 ft. deep. She has a spar deck fore and aft, and will be fitted with compound engines of 70-horse power nominal. The steamer, which was named the *Hebridean*, has been built to the order of Messrs. John M'Callum & Co., Glasgow, and will be engaged in the West Highland passenger, goods, and cattle trade. She is expected to attain a speed of 11 knots an hour.

Lydian Monarch.—On May 2nd the steamship *Lydian Monarch*, built to the order of the Royal Exchange Shipping Company, London, was launched from the dockyard, Dumbarton. The *Lydian Monarch* is the last of three similar vessels built by Messrs. M'Millan for this firm, the two former of which were of iron, and this one of steel. They are all intended for the new Monarch Line, to trade from London to New York, carrying first-class passengers, emigrants, cattle, fresh meat, and a general cargo. The principal dimensions are as follow:—Length, 370 ft; breadth, 43 ft.; depth, 35 ft. 9 in.; tonnage, gross, including shelter deck space, about 4,000 tons. The engines, made by Mr. David Rowan, Glasgow, are compound double-cylinder, inverted, direct acting, of 2,800-horse power, the cylinders being respectively 47 and 87 inches diameter, with a piston stroke of 57 inches, and supplied by steam, at a pressure of 80 lbs, from three boilers having 12 Fox's patent corrugated furnaces. The ship is four-masted, square-rigged on the two foremost, and the amount of canvas available is such that in case of emergency the vessel would be safely navigable by sail alone. The *Lydian Monarch* obtains the highest class in the Societies of Lloyd's and the Bureau Veritas. On leaving the ways the vessel was named by Mrs. W. H. Westhorp, Buckhurst-hill, Essex.

Vixen.—On May 2nd Messrs. Cunliffe & Dunlop launched from their yard at Inch Works, Port Glasgow, a screw steamer, built to the order of Messrs. Mello & Co., Para, Brazil. This vessel, which is intended for passenger and cargo traffic on the Amazon River, has been during construction under the superintendence of Mr. Guilherme Fox, and is of the following dimensions:—Length, 160 ft.; breadth, 25 ft.; depth of hold, 11 ft.; tonnage B.M., 485 tons. After the launch the vessel was moored alongside the builders' wharf for completion, and will be fitted with compound direct-acting engines of 70-horse power nominal, with latest improvements. The ceremony of naming the steamer *Vixen* was performed by Miss Fox, of Broomhill-terrace, Partick.

Taldora.—On May 4th the Campbeltown Shipbuilding Company launched a screw steamer called the *Taldora*, built for the Australian coasting trade to the order of Messrs. M'Ilwraith, M'Eacharn, & Co., of London, and is the second vessel the Campbeltown Shipbuilding Company have built for this firm. The dimensions of the steamer are 130 ft. by 23 ft. by 9 ft. She is of 300 tons burthen, fitted with shade decks, &c., and is admirably adapted for the trade. The vessel has been built under special survey, and will be provided with engines of 60-horse power by Messrs. Kincaid, Donald & Co., of Greenock.

Modena.—On May 5th Messrs. Robert Steele & Co., Greenock, launched from their shipbuilding-yard a steamer built to the order of Messrs. James Currie & Co., Leith, for the Leith, Hull, and

Hamburg Steam Packet Company. The steamer has been built of steel, and is of the following dimensions:—Length, 250 ft.; breadth, 33 ft.; and 17 ft. 3 in. in depth. Her gross tonnage is 1,210, and her nett tonnage 770. She will be fitted with compound surface condensing engines of 120-horse power nominal. The new steamer is similar to the *Ferrara*, which was built for the same owners last year. As the steamer left the ways she was named the *Modena* by Miss Currie, daughter of the Managing Owner.

Sao Felix.—On May 12th Messrs. Heury Murray & Co. launched from their yard a paddle steamer named the *Sao Felix*, of the following dimensions:—Length, 180 ft.; breadth of beam, 23½ ft.; depth of hold, 8 ft. The engines, to be supplied by Messrs. Kincaid, Donald, & Co., Greenock, will be of 150-horse power. The *Sao Felix* has been built for Messrs. Kincaid, Donald & Co., to the order of Messrs, Knowles & Foster, London, and her owner is H.E. the Viscount Marinho of Bahia, Brazil. She is to trade along the Brazilian coast, and will carry passengers and mails.

Fidra.—On May 12th Messrs. Alex. Stephen & Sons launched at Linthouse, Govan, an iron screw steamer, classed 100 A 1, under special survey. She was named the *Fidra* by Mrs. Reid, wife of Mr. Francis F. Reid, of Leith, to whose order the vessel has been built. The *Fidra* is a steamer of about 1,150 tons, of the most modern and improved type, with water ballast arrangements, and all the best appliances for working cargo, &c. Her engines, also Messrs. Stephen's own make, have cylinders 29 and 56 inches diameter by 36 stroke, with a working pressure of 75 lbs. The vessel is intended for the Eastern coasting trade.

Clan Macfarlane.—On May 12th an iron ship was launched from the shipbuilding yard of Messrs. Russell & Co., Glasgow. The vessel has been built to the order of Mr. Thomas Dunlop, of Glasgow, and is of the following dimensions:—Length, 250 ft.; breadth, 38 ft.; depth, 22 ft. 9 in.; tonnage, 1,500 register; to carry a deadweight of 2,400 tons. As the ship left the ways she was named the *Clan Macfarlane*, by Mrs. David Richmond, Broom Park, Pollokshields. She has been furnished with all modern appliances for facilitating the loading and discharging of cargo. It is intended to employ her on the East India trade, and this has been kept in view in her construction and fitting out.

John Smith.—On May 13th there was launched from the shipyard of Messrs. Barr & Shearer, at Ardrossan, a three-masted schooner, built for the Newfoundland fish trade. Her dimensions are:—Length between perpendiculars, 102 ft.; beam, 22 ft. 6 in.; depth of hold, 10 ft. 9 in. The vessel is owned chiefly by Captain Charles Hendry, who has been a shipmaster in the East Indian trade. As she left the ways she was named the *John Smith* (a mark of respect to Mr. John Smith, shipping agent) by Miss Maggie Smith.

Kilmodan.—On May 14th Messrs. Russell & Co. launched at Glasgow a barque of the following dimensions:—Length, 258 ft.; breadth of beam, 38 ft.; depth of hold, 22 ft. 9 in.; of 1,520 tons, and to carry 2,580 tons dead-weight cargo. As she left the ways she was named the *Kilmodan* by Miss Margaret C. Newton, daughter of Mr. William Newton, Eaton Gardens, Glasgow, one of the managing owners. The *Kilmodan* has been built for Messrs. Kerr, Newton, & Co., Glasgow, and is of the same model as the *Cromartyshire*. The *Kilmodan* will load at Port Glasgow for San Francisco.

Rome.—On May 14th the *Rome* (s), constructed by Messrs. Caird & Co. for the Peninsular and Oriental Steam Navigation Company was launched at Greenock. The dimensions of the ship are as follows:—Length, 430 ft.; breadth, 44 ft.; depth, 36 ft.; gross measurement, 5,100 tons. She received her name from Mrs. Barnes, wife of one of the directors. The engines have also been constructed by Messrs. Caird & Co. They consist of four cylinders, having a stroke of 5 ft., surface condenser, centrifugal and other pumps, &c. It may be mentioned that the crank shaft, which is in two pieces, weighs 30 tons. The boilers are six in number, and of steel, and suitable for a working pressure of 90 lbs. The number of furnaces is 30. She has four masts, two funnels, and short poop and forecastle. The ship is provided with powerful appliances for loading and discharging cargo, pumping, extinguishing fire, steering, &c., &c. Those for starting and reversing the engines, controlling them in stormy weather, &c., are of the most modern description. She will carry a large Bell-Coleman refrigerating machine, with cooling chamber. The *Rome* is the largest ship ever built in Greenock, being 100 tons more in gross measurement than the *City of Berlin*, built by the same firm. The *City of Berlin* is, however, 20 ft. longer than the *Rome*.

Lizard.—On May 16th Messrs. Blackwood & Gordon launched from their shipbuilding-yard, at Port Glasgow, the screw-steamer *Lizard*, built to the order of Mr. John Burns for the cargo trade between Greenock and Belfast. The following are her dimensions:—190 by 26 by 14·6. She will be supplied by her builders with compound engines of 100-horse power. On leaving the ways she was named by Miss Blackwood, daughter of the builder.

Craigallion.—On May 7th there was launched from Messrs. Ramage & Ferguson's shipbuilding yard at Leith, an iron screw steamer, named the *Craigallion*, of about 1,000 tons gross register, for Messrs. Walker, Donald & Co., Glasgow. This steamer's dimensions are—216 by 30 by 16 ft. moulded, with engines 20 and 50 by 33 stroke, and her general design is somewhat similar to the screw steamer *Craigrownie*, launched six months ago for the same owners. On leaving the ways the *Craigallion* was named by Miss Glover, Mount Grange, Edinburgh, and was afterwards towed round to the harbour to receive her machinery.

Strathdee.—On May 7th there was launched from the shipbuilding-yard of Messrs. Dobson & Charles, at Grangemouth, a screw steamer, built to the order of Messrs. James Hay & Son, Glasgow, and intended for the West Coast trade. Dimensions—140 ft. by 21 ft. 6 in. by 11 ft.; tonnage, 400. She will be fitted with compound surface-condensing engines of 60-horse power nominal by Messrs. Scott Bros., Engineers, Glasgow, and fitted with all the latest improvements. As she left the ways the ceremony of naming her the *Strathdee* was performed by Miss Isa Charles, daughter of the builder.

Corsican.—On May 17th Messrs. Murdoch & Murray launched from their shipbuilding yard at Port Glasgow an iron screw-steamer, named the *Corsican*, built to the order of Messrs. J. & J. Macfarlane, Glasgow. The following are her dimensions:—215 by 30 by 15, and of between 1,100 and 1,200 tons. She will be supplied with compound engines of 120-horse power by Messrs. William King & Co., of Glasgow.

Skjold.—On May 19th there was launched from the yard of Messrs. Lobnitz & Co., Renfrew, a screw-steamer of the following principal dimensions:—Length of keel and forerake, 246 ft.; breadth of beam, 34 ft. 2 in.; depth of hold, 18 ft.; and is classed in the highest class of Bureau Veritas. She is to be fitted with machinery of 160-horse power nominal. The vessel is built for L. H. Carl, Esq., of Copenhagen, and will be commanded by Captain Aaris, under whose superintendence the vessel has been built. On leaving the ways she was named the *Skjold* by Miss Lobnitz, and immediately thereafter taken into the builder's dock, where she will receive her machinery.

Mauritius Reunion.—Messrs. W. Hamilton & Co. launched from their shipbuilding-yard at Port Glasgow, on May 18th, a handsomely-modelled screw-steamer of the following dimensions:—Length, 299 ft.; breadth, 36 ft.; depth, 25·6 in.; deadweight, 3,000 tons. This steamer will be fitted with compound surface-condensing engines of 250-horse power nominal. She has water ballast throughout on the new cellular principle, and will be fitted with steam steering gear (Bow & McLachlan's patent), steam windlass, and all the latest improvements, and classed 100 A 1 at Lloyd's. She has splendid accommodation for first and second class passengers. This steamer has been built to the order of Messrs. Gravier & Co., Marseilles, for the Company Maurice-Reunion, and is the first of a regular line of steamers, to trade between London, Marseille, Mauritius and Reunion, viâ Suez Canal. On leaving the ways she was named the *Mauritius Reunion* by Mrs. F. G. D. Bryan, of Frederickstadt Drumpellier. We understand the builders have other two steamers of the same size in course of construction for this line, and they have been contracted through a London firm, Pothonier & Co., 21, Great St. Helen's.

LAUNCH.—IRISH.

Asiatic.—On April 30th at high water, about half-past eleven o'clock, a new White Star liner was launched from the shipbuilding yard of Messrs. Harland & Wolff, Queen's Island, Belfast. As is well known, the vessels of the celebrated White Star fleet were constructed by this firm. Large crowds assembled at the quay to witness the launch, in which very great interest was manifested on both sides of the river, and which, we must say, was accomplished in a most successful manner. The new vessel, which is to be named the *Asiatic*, is built of Siemens-Martin steel, is 430 ft. in length, 42 ft. beam, and is about 4,300 tons gross register. Her saloon passenger accommodation is superb, and everything possible has been provided for those who may go steerage. The *Asiatic* will be classed very high on the register. Her engines, &c., are all on the most modern principle, and will be fitted up here by Messrs. James Jack & Co., of Liverpool. The windlass, winches, and steering gear are to be supplied with the latest improvements, and, of course, will be driven by steam. Messrs. Harland & Wolff have at present on the stocks a steamer of similar dimensions to the *Asiatic*, a large steamer for the

Peninsular and Oriental Steam Navigation Company, and a duplicate to the steamer Winnebah, which was launched from the Queen's Island Shipbuilding Yard only a short time since. After the launch a number of ladies and gentlemen were entertained at luncheon on the Queen's Island.

On April 30th Mr. Thomas Norris launched from his yard, at Prince's Dock, a handsome steam yacht, built to the order of Colonel H. S. Beresford Bruce, D.L., Castle-dawson. Its dimensions are—Length, 45 ft.; breadth of beam, 9 ft.; moulded depth, 5 ft. The cabins are raised, and the boiler and machinery, will, it is said, be on the newest principle.

TRIAL TRIPS.

Bothwell Castle.—On April 28th the trial trip of this steamer took place from the yard of her builders to the Royal Albert Dock, London, and was in every way a success. She has been built by Messrs. Raylton, Dixon & Co., of Middlesbrough, to the order of Messrs. Thomas Skinner & Co. to take her place in their Castle Line of steamers to China. The steamer in question will carry 4,000 tons of tea on a draught of water of 21 ft., and on her trial trip, when loaded down to this depth, she maintained an average speed of over 12 knots between the Tees and London. Her leading dimensions are 345 ft. long over all, 38 ft. 6 in. beam, and 26 ft. depth of hold, having a gross register tonnage of 2,550 tons. She is built on the three-decked rule. The deck houses and casings are all of iron, and the decks, charthouse, rails, &c., are of East India teak. Her rig is brigantine with pole masts. The engines, which are of 300-horse power nominal, are built by Messrs. T. Richardson & Sons, of West Hartlepool, and have all the latest improvements. She has steam windlass and steam steering gear, and water ballast in after hold.

Ravensheugh.—On April 30th the new screw steamer *Ravensheugh*, built by Palmer's Shipbuilding and Iron Company (Limited), Jarrow, for Messrs. Bowser & Ormston, Newcastle, had her trial trip at sea. The vessel is 270 ft. long, 35 ft. broad, and 23 ft. deep; and is fitted with a pair of Palmer's celebrated engines of 180-horse power nominal. She is also fitted with Messrs. Bow, McLachlan, & Co.'s (Paisley) steam steering gear, which during the trial acted with great efficiency and smoothness. The *Ravensheugh* is intended for the general carrying trade, and will be under the command of Captain Munro. Owing to the unpropitious state of the weather, it was found impracticable to get the vessel "on to the mile," but the speed obtained was computed at about 11 knots per hour.

Abeona.—On April 30th the screw steamer *Abeona*, built by Messrs. Bartram, Haswell & Co., South Dock, Sunderland, to the order of Messrs. Graham, Anderson, & Co., wholesale timber merchants, of Maryport, Carlisle, and Tyne Dock, was taken to sea for her trial trip. The following are the dimensions of the *Abeona*, which is registered at Newcastle:—Length between perpendiculars, 200 ft.; breadth of beam, 30 ft.; and depth of hold, 15 ft. 6 in. Her total deadweight carrying capacity is about 1,250 tons. She is fitted with steam windlass, winches, &c., for the rapid loading and discharging of cargo. The steamer is fitted with compound surface-condensing engines of 100-horse power, by Mr. John Dickenson, of Sunderland, and they combine all the latest improvements in Marine engineering. The building and fitting out of the vessel have been carried out under the inspection of Captain Mail, superintendent for the steamers belonging to Messrs. Westoll & Co., of Sunderland. The speed of the vessel was tried with and against the tide, and the result was that a mean speed of about 9½ knots an hour was obtained. The engines worked with perfect smoothness, and the speed was considered highly satisfactory.

Huntingdon.—On May 5th the new screw steamer *Huntingdon*, recently built to the order of Messrs. W. Milburn & Co., of Newcastle, made a successful trip to sea. This vessel is 300 ft. long, 36 ft. wide, with a depth of 26 ft., and is supplied with engines of 260-horse power. She made about 12 knots per hour. In connection with the trip a new lifebouy was exhibited on board. To test its qualities four of the company got into the lifebuoy, which was lifted by a derrick usually employed for discharging vessels, and was deposited in the water. The buoy, with its living freight, was afterwards towed into the Tyne by a steam-tug.

Grangefell.—On May 7th the trial trip of the screw-steamer, *Grangefell*, built by Messrs. R. and J. Evans & Co., of Brunswick Dock, Liverpool, to the order of Messrs. Hume, Smith & Co., took place on the measured mile on the Mersey, when the vessel attained the speed of 10¼ miles per hour, the engines working at 87 revolutions per minute. She has been specially constructed for the Workington trade, carrying railway iron, and is of 2442 tons gross and 143 nett register. Her dimensions are 120 by 22 by 10, and she has been supplied by Messrs. David Rollo & Sons with a steel boiler, capable of bearing 80 lbs. pressure, and engines of 55-horse power, cylinders 17 and 32 in. diameter, having a 26-in. stroke. In addition to the testing the speed of the vessel over the measured mile her capabilities were further proved by a run as far as the Bar Lightship. The *Grangefell* will be under the command of Captain Tarbot.

Ban Whatt Soon.—On May 11th the new screw steamer, *Ban Whatt Soon*, built and engined by Messrs. Blackwood & Gordon for a Chinese firm, went on her trial trip. The measured mile was accomplished, notwithstanding the steamer being heavily loaded, at over 10 knots, being above contract speed.

Iron Acton.—On May 11th this steamer, which has recently been built by Messrs. Raylton Dixon & Co., of Middlesbrough, to the order of Messrs. King Brothers, of Bristol, proceeded on her trial trip. Her dimensions are:—Length over all, 235 ft.; breadth, 32 ft. 6 in.; and 16 ft. depth of hold; and she will carry about 1,450 tons deadweight. She has been designed specially for the Baltic timber trade, in which she will be principally employed by her owners. She has iron decks right fore and aft, cabin accommodation under the bridge, water ballast in both holds and engine-room, and has been fitted with engines of 100-horse power by Messrs. Thomas Richardson & Sons, of Hartlepool. After adjusting compasses off the mouth of the Tees, she proceeded on her trial trip to the Tyne, on which, with her tanks full, she maintained a speed of between 10 and 11 knots.

Trevilley.—On May 11th the *Trevilley* (s.), built by Messrs. T. Redhead & Co., of South Shields, made a successful trip to sea. This vessel is 245 by 32·9 by 11, is classed 100 A 1 at Lloyd's, and has been built to the order of Messrs. E. Hain & Son, of St. Ives, Cornwall. This is the third vessel Messrs. Redhead have built for the same owners. On her return to Shields from sea she was taken up the Tyne to Pelaw Staithes to load a cargo of coals for Civita Vecchia.

Quettah (s.)--On May 17th the *Quettah* (s), launched by Messrs. Wm. Denny & Brothers, Dumbarton, for the British India Steam Navigation Company, went down the Clyde on a trial trip. The *Quettah* is a vessel of 380 ft. by 40 ft. by 30 ft. 6 in., and about 3,400 tons. She is intended for the London and Calcutta Line of the British India Steam Navigation Company. She has compound surface-condensing direct acting inverted cylinder engines of 500-horse power, constructed by Messrs. Denny & Co., Dumbarton. She is fitted for a large number of first and second class passengers. Amongst other features of the vessel, she is fitted with hydraulic gear for the purpose of discharging the cargo, steering the ship, heaving the anchor, as well as working a 30-ton capstan aft. The principal feature of this gear is that the cargo can be discharged with greater speed than by steam winches, and at the same time with an absence of noise. The hydraulic gear was prepared by Messrs. Brown Brothers & Co., Edinburgh and London. The automatic steering is due to a combination of electric and hydraulic machinery, under a recent patent, by Messrs. Brown & King. The ship on her trials behaved in a most satisfactory manner. With 2,070 tons on board she attained a speed of about 14 knots an hour. The engines worked with the greatest smoothness.

Perseverance.—On May 17th the screw steamer, *Perseverance*, of Sunderland, left the South Dock on her trial trip, previous to her proceeding on her first voyage to the Mediterranean. The steamer, which was built by Messrs. Short Bros., Pallion, to the order of Messrs. Freear & Dix, is rigged as a brigantine, and is of the following dimensions:—Length over all, 226 ft.; between perpendiculars, 220 ft.; extreme breadth, 32 ft. 5 in.; depth of hold, 16 ft. 3 in. Her registered tonnage is 717 tons. When she left the dock she drew 15¼ ft. of water, carrying 1,500 tons of coals, including bunkers. She has a half-poop to bridge, with full topgallant forecastle, and her decks are of iron. Her classification is the highest in Liverpool registry. After her launch the vessel was fitted with a pair of direct-acting compound surface condensing engines of about 110-horse power by Mr. John Dickinson, of Palmer's Hill. All the latest improvements are combined, including boilers of 80 lbs. pressure, adapted to consume any class of coal, fitted with Churchill's steam governors. After leaving the entrance, the vessel steamed southward past Seaham until the compasses had been adjusted, and then her head was turned north and she proceeded nearly to the Tyne, the engines running very smoothly and all the machinery on board working with perfect freedom. The log was put over, and after a lapse of half an hour it was found the vessel had been travelling at the rate of 10 knots per hour, a speed highly satisfactory to all concerned. The engines worked at the rate of 62 revolutions per minute.

Kingsley.—On May 19th the screw steamer, *Kingsley*, built by

Messrs. T. & W. Smith, North Shields, was taken to sea for her official trial trip. The *Kingsley*, which is owned by Messrs. Ed. Eccles & Partners, Newcastle, is a vessel of 180 ft. in length, 30 ft. 3 in. in beam, and 13 ft. 6 in. draught of water. Her nett register is 450 tons. She is destined for the coasting and Bilbao trades. She has steam winches, steam windlass, three of Archer's patent hoists, together with other machinery for quick despatch in discharging cargo. She was engined by Messrs. R. & W. Hawthorn, Newcastle, who put in one of the usual compound surface condensing engines, of 100-horse power. The engine is fitted with Marshall's patent valve gear for rapid reversing of the engine. She has also one of Durham's governors for controlling the propeller's speed when in a seaway. The vessel was loaded previous to the trial to a mean draught of 12¼ ft. and she registered a speed of between nine to ten knots an hour when on the measured mile.

Three new gunboats, built by Messrs. C. Mitchell & Co., Low Walker, on the Tyne, engined by Messrs. R. & W. Hawthorn, of Newcastle, and armed by the Elswick Ordnance Works, left the Tyne on May 19th. They are named the *Iota*, *Kappa* and *Lambda*, and are built of steel. The *Lambda* will proceed to Canton, and the *Iota* and *Kappa* to Tientsin; they are in chief command of Captain John Ross on their passage out. They will be followed by two powerful turret ships, which are nearly ready for sea. The crews of all the vessels are Chinese.

Aristides.—On May 21st this steamer was taken for a run outside the Mersey. She has been built to the order of Messrs. Layborne & Legge, Steamship Owners, by Messrs. T. Roydon & Sons, and engined by Messrs. J. Jack & Co. Her carrying capacity is 2,300 tons, and she is fitted with all approved modern appliances. The speed on the measured mile was 10¼ knots, which was considered very good for the power employed; and the consumption of fuel will also be small, a novelty in her machinery being the split boss propeller, intended to overcome the loss of time usually taken up in overhauling, and at the same time giving greater security against becoming loose while working. After the trial the steamer was placed on her berth for loading, and will be immediately despatched for Rangoon. She has been superintended throughout by Messrs. Cooke & Mylchrest, and will be commanded by Captain De Silva.

Pembroke.—The *Pembroke*, steel paddle-wheel steamer, recently completed by Messrs. Laird Brothers, Birkenhead, for the Great Western Railway Company, for their express service between Milford and Waterford, has just been put on her station, and made the first run over at a speed of 15·42 knots, and the return voyage in 5 hours 49 minutes, giving a speed of 14·97 knots.

A six hours' continuous steam trial was recently made at Portsmouth of the two gunboats, *Bouncer* and *Insolent*, which had been brought round from Pembroke, where they were built. These craft are 87 ft. long and 26 ft. in beam, and, with the sister ships, *Pincher*, *Tickler*, *Gadfly*, and *Griper*, were engined by Messrs. John Penn & Co., of Greenwich. Though the machinery is in all respects the same in all the gunboats, having cylinders of 20 in. diameter, of which the trunk is 11¼ in., and a stroke of 1 ft. 3 in., the last two boats differ in some important respects from the four others. They are constructed of steel instead of iron, and are besides provided with bow rudders to assist in turning. The draught of both vessels was the same—viz., 6 ft. forward and 6 ft. 6 in. aft. With a mean of 154 revolutions, the *Bouncer* developed 228 horse-power, and realized a speed of 8·021 knots; while with 156 revolutions per minute the *Insolent* developed 232 horse-power and attained a speed of 8·064 knots an hour. The performances of each vessel are thus practically the same. The trials were perfectly satisfactory, the contract power being 168 horses. The *Bouncer* and *Insolent* are intended for coast defence, and will each carry one large gun.

Dawn, (s.s.)—This steamer, built to the order of the Tobago Steamship Company, Limited, had her trial trip on the river, Friday, May 20th. Length, about 100 ft., breadth, 15 ft., and depth 8 ft. 6 in., carrying capacity 100 tons, and speed 9 knots. This vessel is intended for use on the coast of Tobago and from that island to Trinidad; thus performing the work at present done by sailing vessels. We understand that the enterprising manager, Mr. Dawson, has secured a subsidy from Her Majesty's Government for the carriage of the bi-monthly mails between the Islands and Trinidad where they are reshipped on board the mail steamer for Europe. We are happy to say the trial trip fully came up to the anticipations of the owners, and Messrs. Pile & Co., of 34 Great St. Helens, London, the contractors.

THE *American Manufacturer* says China's mercantile marine compares very favourably with Great Britain's, the tonnage of the former being 4,100,000, and of the latter, 6,115,638.

Correspondence.

[*It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.*—ED.]

LOOSE PROPELLER.

To the Editor of the MARINE ENGINEER.

DEAR SIR,—You kindly inserted a letter of mine some time ago, regarding the recognition by the Board of Trade to engineers of merchant steamers for exceptional services rendered in the case of accidents to machinery at sea. There is a case recently of the chief engineer of a steamer going out to China having a loose propeller. Instead of incurring a heavy expense in docking or otherwise, he constructed a tube from tarpaulins with hoops inside and an old cask at the bottom, weighted to sink. He then made two pockets for his arms, with a glass in a suitable position to enable him to examine the defects. He was able to screw up the nut, and also fit a new key to secure it. Surely when a man brings his skill and presence of mind to bear in cases like this, not only saving expense and possibly delay the ship, independent of any pecuniary consideration, it would only be just if the Board of Trade were to recognize such services. Seeing that your journal is getting widely known among engineers, and is carried on in these interests, perhaps you would kindly bring cases of this kind before your readers. There are others I could mention equally deserving of notice, and I am sure it would give great pleasure to the majority of your readers to see them recorded in your journal.

I am, yours truly,
I. M.

St. Vincent, *April 16th*, 1881.

THE TONNAGE OF SHIPS.

To the Editor of the MARINE ENGINEER.

SIR,—With reference to the letter in your last number, it may be of interest to your readers to know that some doubts have arisen as to the meaning of the Statutes. Under the merchant Shipping Acts the tonnage is found by measuring the whole space included in the ship, and then making certain deductions; but Mr. Chamberlain is introducing a Bill declaring that the proper meaning of the Statutes is that nothing be included in the deductions that has not first been included in the measurement.

Yours obediently,
S. P. WILDING.

23, Rood Lane, London, E.C.

LONDON, JULY 1, 1881.

EDITORIAL NOTES.

THIS month has witnessed the launch of one of the most novel and striking additions to our Navy. We speak of the *Polyphemus*. This vessel we have already frequently referred to in its course of construction, and a detailed description of it will be found elsewhere. The rapid and grotesque modifications in the shape and armament of modern war-vessels must be perplexing in the extreme to the old school of sea-men. We should imagine that the modern monsters can be anything but pleasing to those who have such a vivid remembrance of England's old "wooden walls" that walked the waters like things of life. The present mastless iron-clads, of which the *Polyphemus* seems the ultimate absurdity, can only be compared to gigantic lizards or reptiles crawling almost immersed on the surface of the deep. There is, however, a diabolical intentness and determination for mischief about the *Polyphemus* that warrants remark. It will be a bold crew that ships aboard her in time of war. She is formed but to rush upon the foe with resistless speed and force, and to destroy her opponent or be herself destroyed in the attempt. She is provided with no guns, so there can be no dilly-dallying at long or even short ranges. Such play would be destruction to her as she cannot reply; but must at once rush in and decide the contest. At present, she would seem to have somewhat the advantage as against any present iron-clad, as she is considered shot-proof from the obliquity of her angles. We cannot but think, however, that some means to stay the rush of such a marine-destroyer will shortly be found, now that the monster himself is in evidence. It has been whispered that a small and rapid boat, provided with dymanite or torpedoes would prove amply efficient to bell this cat. Or a boarding party, after the Gatling guns and their turrets have been disabled by a few well-directed shots, could not be easily got rid of, and might soon effect an entrance. One of the signs of the times, however, is the happy dispatch in marine warfare to which we are more and more rapidly approaching.

THE launch of the *City of Rome* at the Barrow Shipbuilding Works was the scene of a serious boiler explosion, by which four men unfortunately met their death. It is incredible that such carelessness in the use of steam can exist amongst men who have any acquaintance whatever with steam boilers. A man who is said to have had considerable experience is stated to have allowed the pressure on his boiler to rise to 70 lbs., instead of keeping it at the proper working pressure of 40 lbs. If the boiler was provided with proper safety valves, it is not easy to imagine how such an excess pressure could have arisen, unless by jamming down the valves. In that case the criminal wilfulness and disregard of danger is equally difficult to believe. It seems to us that there will be no protection against such loss of life from explosions until all boilers are so fitted with lock-up safety valves that they cannot be tampered with, and also with low water alarms, so as to protect the boiler against the apparently wilful tampering and astounding negligence of the attendant. The only other protection in such cases is for the attendance upon boilers to be looked upon as an art or business requiring proper attention and training. We certainly fail to see why a boiler with all its possible powers of destruction should be considered a less important charge than an engine; and yet we see the former often in charge of an ignorant labourer, whilst the latter is given into the care of an intelligent artizan, whose whole life has been devoted to learning the duties of such a charge.

MESSRS. SAMUDA BROS. have just launched from their yard a novelty in mechanical appliances. It consists of a floating derrick or crane, capable of lifting a load up to 30 tons to a height of 60 ft. above the water. The crane can traverse a circle of 47 ft. radius, and is driven for lifting and rotation by engines under the control of a single man. The vessel is 100 ft. long, and 44 ft. broad, and the crane is 70 ft. high. This floating crane may probably effect a great improvement in the facilities for transporting heavy weights from craft to craft, or from the quay to a ship's hold with greater celerity and efficiency than can be done with a fixed derrick. For masting or dismasting vessels, or for repairing or replacing heavy boilers or machinery, this floating crane will prove eminently serviceable. It has been designed, and the crane and machinery constructed, by Messrs. Hunter & English for the London and Saint Katherine's Dock Company for use in their New Royal Albert and Victoria Docks.

A GOOD deal of atttention is now being paid to the subject of salvage by raising sunken vessels. The field for profit must be enormous, as many millions per annum are sunk by collision or foundering in comparatively shallow water. The only difficulties to deal with are the mechanical ones attaching to the difficulty of raising such heavy weights as the hulls of vessels without injury to them by the very lifting strain. The method which seems to be the most practically successful is to first stop all the leaks and hatches, and then pump the vessel empty. She will in such case rise by her own lightened weight, and float naturally. The chief difficulty experienced under these circumstances is the proper closing of the leaks and hatches by the divers. If this cannot be done the only alternative is to lift by grappling chains, and the proper attachment or under-laying of these form the chief obstacle to success. There is, however, little doubt that a few years' experience of different systems will at last develop a variety of successful methods, one or other of which may be relied on to raise any vessel from moderate depths, which is not too badly destroyed. This should be a great saving to the nation annually, as much valuable property lies wasting and rotting around our coasts. We see the Liverpool Salvage Association has successfully raised a steamer, sunk by a collision at the mouth of the Mersey.

EXPERIMENTING with torpedoes is expensive work, as each costs about £300. We see that one was lost the other day in the river, and that boats are occupied in dredging and searching for it. This torpedo is of either a secretive or adventurous disposition. It has disappeared and left no trace. It is not known whether it has buried itself in the Thames mud or whether it has gone to sea on its travels. It is to be hoped that it was not primed with its destructive charge, or it would be an unpleasant traveller to meet in its wanderings. We should suggest that if the torpedoes, like pet mice, are given to wandering, a clue should be retained as to their movements and whereabouts by means of a stout cord attached to their tails.

THERE is little doubt that electric lighting will shortly be generally used on board our ironclads. The difficulty has hitherto been the sufficient and simple subdivision of the light for the smaller cabins and state-rooms. This has now been attained on the incandescent system by Mr. Swan, and we see that his plan of lighting has been successfully applied to the cabins and 'tween decks of the *Inflexible*. The lights are of not greater brilliance than an ordinary gas jet, viz., about 16 candles each, and are, therefore, in every way suitable for small and confined situations. The admiral's and captain's cabins were lighted by two series of 48 lights, and the main deck, containing the ward-room and officers' cabins, by three series of 72 lights. The port, ammunition and other passages were also illuminated with a series of lights, and the whole were driven from a single circuit. The result of the experiment was highly gratifying to the inventor, as he had never driven so many lights from a single circuit before. The lights were suspended from wires about a yard apart.

MEETING OF SEA-GOING ENGINEERS.—On Wednesday night, June 1st, a meeting of sea-going Engineers was held in the office of Mr. W. J. Watson, Norfolk-street, Sunderland, for the purpose of forming an association similar to the British Shipmasters' and Officers' Protection Society. Mr. W. J. Watson presided, and Captain J. Henderson, Secretary of the British Shipmasters' and Officers' Protection Society, was also present. There was only a small attendance of sea-going Engineers. The Chairman said all those things had very small beginnings. The first meeting of the Shipmasters' Society was only attended by 8 or 10 persons, and the second by about 20. It now numbered about 2,000 members. The Board of Trade having directed their attention to sea-going Engineers, he thought it was absolutely necessary that they should form a society to protect themselves. They were a large and influential body of men, and ought to take some interest in their own welfare. There were about 2,000 Engineers going to sea, and they had no society to protect themselves. He thought it wou'd be for their own interests to form a society similar to the Shipmasters' Society. They had also a widows' and orphans' fund, so that the surplus money came back to the members in case of death. His object in calling the meeting was to raise discussion. He thought it would be advisable to get a committee formed, and go a little further into the subject, and have it further discussed at some future time. A desultory conversation ensued, and it was stated that the Engineers had already two associations, the Sea-going Engineers' Association and the Amalgamated Society of Engineers. The objects of these societies were similar to those proposed by the chairman. They had funds for giving compensation for loss of clothes, injuries, and funerals. The chairman said he was not aware, until that evening, that such societies were in existence, and, therefore, it was not necessary to take any further action in the matter. The meeting then concluded.

THE PREVENTION OF FOULING IN IRON SHIPS.—The prevention of fouling in the hulls of iron ships is a matter that has long engaged the attention of those interested in the construction and equipment of iron vessels. Many methods have been tried in order to protect vessels against the growth of barnacles in tropical waters, but it can scarcely be said that any of these have proved entirely successful. At present, ships require to be periodically docked and cleaned, and this entails not only a loss of time, but considerable expense. Much interest is therefore taken in a new ship which was launched from the shipbuilding-yard of Messrs. T. B. Seath & Co., Rutherglen. This vessel, which is named the *Bessie*, is built from designs by Mr. G. L. Watson, naval architect, for Mr. John Clarke, Paisley, and is intended as a tender for the yacht *Condor*. The novelty about the *Bessie* is that it is covered over the hull, to six inches above the water line, with a plate of zinc, and by means of this it is believed that the vessel will be thoroughly proof against fouling. The thickness of zinc employed is not great, and it is fitted so closely as not to interfere in the slightest with the delicate outlines of the vessel, but its thickness is sufficient to last, it is calculated, for fully six years. The patentees of this system are Mr. J. Jepson Atkinson, barrister, and Mr. C. F. Henwood, naval architect, of the Middle Temple, London. The well-known action of iron on zinc in salt water led to the discovery of this invention ; but while the use of zinc was well known, the difficulty of attaching it to the hulls of ships remained. Mr. Atkinson and Mr. Henwood have completely overcome this difficulty, and there can be no doubt that the use of their system will be watched with much interest by the shipping community. The method employed in fixing the zinc is simple and effective. The zinc sheets are attached to the iron plating of the vessel at spots nine to twelve inches apart, and at these spots a mechanical joint is made by an alloy or solder, the surface of the spots being about an inch and a-half square. The method of attachment causes the zinc to act like copper on the bottom of a wooden ship. Zinc in the ordinary seaway coming in contact with iron oxidises to the extent of about two to three ounces per square foot in a year, but by attaching zinc of sufficient thickness the vessel can be kept at sea for several years without docking, cleaning, or painting. Scraping will not be required, and the speed of the ship will not be diminished by the growth of barnacles. Mr. H. N. Moseley, of the University of London, has expressed himself satisfied with the chemical action of the new process, and there can be no doubt that the invention will, if successful, be of immense importance to shipowners. The career of the vessel will consequently be watched with great interest.

H.M.S. POLYPHEMUS.

On Wednesday afternoon, June 15th, at 10 minutes before 3 o'clock, there was successfully launched from the Royal Dockyard at Chatham one of the most remarkable examples, if not the most remarkable example, of naval architecture ever floated in connexion with naval warfare. This vessel is the double-screw steel armour-plated torpedo-ram *Polyphemus*, the construction of which was commenced on the 21st of September, 1878. The chief mission of the *Polyphemus* will be to act as a ram and torpedo vessel, and with this work in view most of the considerations which obtain in other ships of war have been set aside—safety and speed, of course, excepted, although the thinness of her armour would at the first glance lead to the conclusion that even safety has been neglected. This, however, is not so, as will presently be seen. It is to be borne in mind that the *Polyphemus* is, after all, only an experimental vessel, embodying the most practical and advanced ideas of those who advocate the principle upon which her design has been based. For the design the country is indebted to Mr. R. Barnaby, C.B., Director of Naval Construction, who has worked out every detail, keeping the object in view, as above stated, steadily in mind. It is quite possible that exceptions may be taken by some to this vessel, but it should be borne in mind that this, like all other departures from the beaten track in naval construction, is but an experiment, although a big and an essentially practical one. There is, however, no way by which the Admiralty are able to demonstrate a principle, except by construction on the actual scale required by practice. Anything short of this would be practically valueless.

The hull proper—that is to say, the iron and steel construction—of the *Polyphemus* resembles somewhat that of the once celebrated *Winaus* cigar-ship—that is to say, she is more or less pointed at the ends, while her midship section approaches the circular ; more nearly, however, resembling an ordinary ship with an arched deck. Upon this structure is mounted a superstructure of iron and timber, consisting of a main deck running fore and aft, and above it a hurricane deck. At intervals along the sides of the hurricane deck will be placed six turrets—three on either side—which will carry the heaviest class of Nordenfelt guns. Protruding upwards through this deck are two protected conning towers, one at each end, which are rigidly connected with the main structure of the vessel, and which form means of ingress and egress to and from her interior. There are also two ventilators and a smoke funnel, which are likewise connected with the main body of the ship. The superstructure itself may all be shot away without in any way injuring the vessel proper or impairing her powers, save only as regards the Nordenfelt guns. The steam steering apparatus is placed below, over the after boiler room, and the steering room is in telegraphic communication with the forward conning tower. The steering apparatus can, however, be actuated from the conning tower by manual gear which is fitted therein. As the *Polyphemus* carries no canvas, masts are dispensed with, and beyond a flag-staff or two nothing will appear above her decks but the towers, the ventilators, and the funnel. She will be propelled by twin screws, which are carried in framings, one on either side near her stern. These screws are three-bladed, 14 ft. in diameter, from 15 ft. to 17 ft. pitch, and with a blade surface in each screw of 45 ft. She is also fitted with two rudders, which are placed under her hull near her bows, and can be lowered for use and raised again into recesses in which they are ordinarily carried. They are intended to be used for special manœuvring purposes. The ram projects some 14 ft. beyond the body of the vessel, and is made hollow for the discharge of Whitehead torpedoes. The port or opening is covered by a solid steel cap, which forms the ram-point, but which, by means of a twisted sliding bar, can be easily pushed forward and turned up to allow of the discharge of the torpedo some 8 ft. below water-level, and is as easily closed afterwards. Besides this, there are four other torpedo ports for the discharge of the same class of weapon, two being placed on either side of the vessel near the bows. She will also carry spar or deck torpedoes.

The framing of the *Polyphemus* is of Landore-Siemens steel, over which is a double layer of ½-inch plates of the same material. Upon this, again, is superimposed a plating of Whitworth fluid compressed steel, the plates measuring 10 ft. long by 2 ft. 6 in. deep and 1 in. thick. Her outer armour consists of small plates or scales, also of Whitworth compressed steel, measuring 10 in. square by 1 in. thick, running off to ¾ in. at the ends. The plates are fastened on by five screws, one at each corner, which holds three other plates, and one in the centre. This plating covers her curved deck and extends a short distance down below water level. The vessel measures 240 ft. long between perpendiculars, and has an extreme breadth of 40 ft., with a depth of hold of 18 ft. 9 in.

Her immersed midship section is 625 square feet, and she draws 19 ft. 6 in. of water forward and 20 ft. 6 in. aft, her displacement load being 2,640 tons. Her engines, which are by Messrs. Humphrys, Tennant & Co., are of the compound, horizontal, single piston-rod type, having four cylinders, the two high-pressure being 38 inches in diameter, and the two low-pressure 64 inches in diameter, with a 39-inch stroke. Her indicated horse power is 5,500, and her estimated *maximum* speed 17 knots. Steam will be supplied from 10 boilers of the locomotive type, at a working pressure of 120 lb. per square inch, they having been tested to double that pressure—viz., 240 lb. per square inch. The air-compressing machinery for the torpedoes and the steam steering apparatus are by Mr. Peter Brotherhood. The weight of the machinery, inclusive of the water in the boilers and 10 tons of spare gear, is 490 tons.

Such is the *Polyphemus*, the most recent addition to the Royal Navy, which, in spite of her peculiar construction, will not, when finished, by any means present an unsightly appearance afloat, but rather the contrary. Although carrying no heavy guns, her offensive powers will be very great as a ram and a torpedo craft, while her ability to manœuvre rapidly and to move at great speed, combined with her peculiar outward form, which presents a variety of oblique angles to the enemy's shot, form her chief means of defence. Should she, however, receive a shot she will not be in imminent danger, as she is divided into a great number of water-tight compartments. From the nature of her construction she will have to be for the most part artificially lighted below, while air will also have to be artificially supplied to her, so that her crew, who will number 130, will not, perhaps, have the most enviable life while she is in commission. But with all this she forms a most formidable addition to our Navy, and one, moreover, the stability of which is perfectly assured.

The launch of this interesting vessel took place with punctuality. After the customary religious service by the chaplain, the christening ceremony was performed and the launch practically effected by Mrs. G. O. Trevelyan, wife of the Secretary to the Admiralty. By simply pushing forward a lever that lady released the dog-shores and at the same time actuated a piece of mechanism by which the traditional bottle of wine was dashed against the bows of the vessel, which were wreathed with flowers. With an uttered good wish from Mrs. Trevelyan, the *Polyphemus* glided down her ways into the river amid the plaudits of the spectators, who had assembled to the number of several thousands, and the strains of the National Anthem, played by the band of the Royal Marines, which was in attendance. There was a large and distinguished company present upon the platform, which included Admiral Sir George Sartorius, Admiral Sir Houston Stewart; the Admiral-Superintendent, Admiral Brandreth; the Colonel Commandant of Marines, Colonel Connolly; the chief officials of the Admiralty and of the Dockyard; Lord Randolph Churchill, M.P.; Mr. Gorst, Q.C., M.P., the local member, and Miss Gorst; Mr. Brassey, M.P., Mr. P. Stewart Macliver, M.P., and Captain J. W. Gambier, R.N. The naval representatives of the various foreign Governments were also present. The vessel was built and launched under the superintendence of Mr. R. P. Saunders, chief constructor of the dockyard, and Mr. Penny, the senior foreman in charge. The *Polyphemus* was launched with her engines on board, and will be taken into dock and got ready for her steam trials, which will be carried out at an early date, and which are looked forward to with general interest.

LAUNCH OF THE "CITY OF ROME."

THE Barrow Shipbuilding Company launched from their yard on June 14th the steamer *City of Rome*, which has been built to the order of the Inman Line, and intended for the Liverpool and New York station. As this steamer is the largest in the world after the Great Eastern, much interest was taken in the launch, which passed off very successfully, Lady Constance Stanley performing the ceremony of "christening." We gave an account, with illustrations, of the *City of Rome* last year (*vide* September number), but it will be convenient that we should give some particulars concerning the vessel here. The *City of Rome* is the seventy-seventh vessel constructed by the company. Amongst these may be named, s.s. *Duke of Devonshire*, 3 000 tons, launched June 25th, 1873; s.s. *Duke of Buccleuch*, 3,000 tons, launched October 9th, 1873; s.s. *Duke of Lancaster*, 3,000 tons, launched April 16th, 1874; s.s. *Anchoria*, 4,170 tons, launched October 23rd, 1874; s.s. *Devonia*, 4,270 tons, launched March 28th, 1877; s.s. *Circassia*, 4,270 tons, launched March 19th, 1878; s.s. *Belgenland*, 3,692 tons, launched December 24th, 1878; s.s. *Rhynland*, 3,689 tons, launched March 10th, 1879; s.s. *Furnessia*, 5,500 tons, launched October 19th, 1880; &c. The following are the dimensions:—Length over all, 610 ft, length between perpendiculars, 586 ft., extreme, breadth 52 ft. 3 in., depth of hold, 37 ft., tonnage, 8826 tons, indicated horse power, 10,000. It was stipulated that the vessel should combine the highest rate with the maximum of comfort and conveniences, such as are only to be found in the best modern hotels. The distinctive type of the Inman Line has not been departed from in respect of the perhaps old-fashioned, but still handsome profile, with clipper bow, figurehead and bowsprit. The figurehead is a full length figure of one of the Cæsars in the imperial purple. The whole of the headwork with this exception is formed of iron, to save the cost and trouble of continually renewing the head-rails, &c., when made of wood. The vessel is to be rigged with four masts; and here again the handsome full ship rig of the Inman Line has been adhered to with the addition of the fore and aft rigged jigger mast, rendered necessary by the enormous length of the vessel. She will have three funnels, each painted with the company's white band. A point calling for special notice is the large number of separate compartments formed by water-tight bulkheads, each extending to the main deck. The largest of these compartments are only about 60 ft. long; and supposing that, from collision or other cause, one of these were filled with water, the trim of the vessel would not be materially affected. The Mersey frame or post made at the Mersey Iron and Steel Works, is the largest single forging ever made for such a purpose; the finished weight is no less than 33 tons, as compared with 18 tons in the sternpost of the *Furnessia* of 5,500 tons. The framing of the vessel is of the ordinary type, the floors being 34 in. deep at the centre line. There are two complete, while the lower deck is complete for half the length, and has wide plating on each side for the remainder. The question of propelling this great vessel at so high a speed, namely, 18 knots per hour, was one that demanded long and careful consideration. It was ultimately decided that it would be better to adhere to the single-screw arrangement, and to adapt a propeller 24 ft. in diameter, driven by three sets of inverted "tandem" engines, working on three cranks disposed at an angle of 120 deg. with one another. The "tandem" engine has the high-pressure cylinder placed in a line behind or above the low-pressure cylinder. Each high-pressure cylinder is carried upon three wrought-iron columns, thus giving plenty of light, and easy of access to the stuffing-boxes; and also enabling the cylinder covers, which are made in halves, to be readily withdrawn. The slide valves are driven by an independent shaft, worked by two pairs of mortice wheels, one at each end of the engines, an arrangement which has the advantage of requiring comparatively small eccentrics. The crankshaft is a built shaft, and together with the screw shafting has been made by Sir Joseph Whitworth & Co., of their fluid compressed steel. The shafting is made hollow, and by the following process: Each length is made from a hollow cylindrical ingot, which, while in the molten state, is subjected to a heavy hydraulic pressure. The ingot is afterwards reheated and placed on a mandrel and is then forged and drawn by hydraulic pressure, until it ultimately assumes the form of a double collared shaft. The leading particulars of the engines are as follows:—

There are three high-pressure cylinders 43 in. in diameter and three low-pressure cylinders 86 in. in diameter, and 6 ft. stroke. The diameter of the crankshaft is 25 in., and of the crankpins 26 in. The length of the main bearings is 33½ in., and of the crankpins 28 in. The crankshaft, as built up complete, will weigh 64 tons; had it been made of iron and solid, the weight would have been 73 tons. The propeller shafting is 24 in. in diameter, and the hole through it 14 in. in diameter. The thrust shaft has thirteen collars, 39½ in. in diameter, giving a surface of 6,000 square inches. This piece of shafting weighs 17 tons. The propeller shaft is 25 in. in diameter, and 30½ ft. long, and weighs 18 tons. The engine bedplate weighs 100 tons. The cooling surface of the condensers is 17,000 square ft., equal to nearly 17 miles 360 yards of tubing. There are two air-pumps, 39 in. in diameter, and 3 ft. stroke; these pumps, and the feed and bilge pumps, being worked by levers attached to the aft and forward engines. There will also be a large centrifugal pumping engine, which can either be used for pumping heavy leaks, or to discharge through the condenser. There will also be three auxiliary pumping engines, for feeding the boilers, for bilge pumping and for deck purposes. Steam will be supplied by eight cylindrical tubular boilers, fired from both ends. Each boiler is 14 ft. mean diameter, and 19 ft. long, with a steam receiver 13 ft. long and 4 ft. in diameter, and has six furnaces 3 ft. 9 in. in diameter, three at each end, so that there are forty-eight furnaces in all. The firebars are 6 ft. long, giving a grate surface of 1,080 square ft. The shell plates of the boilers, supplied by Sir John Brown & Co., are 24 ft. 8 in. long, 4 ft. $4\frac{1}{2}$ in. wide, and $1\frac{1}{4}$ in. thick, and weigh nearly $2\frac{1}{2}$ tons each; all the holes are drilled. The internal parts are of Bowling iron, and each furnace has its own separate combustion chamber. These boilers are constructed for a working pressure of 90 lb. per square inch. The engines are intended to work constantly at 8,000 indicated horse power, although they are capable of developing 10 000 horse power indicated.

The internal arrangements for the comfort and convenience of the officers, crew, and passengers of the huge floating palace are to be of the most elaborate description. There are two large smoking-rooms, which will be highly decorated and fitted up in the most approved style, each saloon having a separate entrance. In the after deck-house there is a commodious saloon, which is to be furnished in the most elegant manner as a lounge for ladies. The upper saloon, or drawing-room for the use of passengers, is a handsome apartment in the form of a wide gallery with lounges round the sides and a large rectangular opening into the dining-room below. Above this opening is a large skylight richly ornamented. At the fore end of this saloon will be placed a grand piano, and at the after end is the staircase leading to the dining-room. The estimated weight of the vessel complete and ready for sea is 8,000 tons, and her displacement at 26 ft. mean draught is 135,000 tons, so that she will have a dead weight of carrying power of 5,500 tons. The cubical contents of her hold will give her a measurement capacity of 7,720 tons at 50 cubic feet to the ton.

Arrangements which were made to secure the successful launching of this vessel are not without interest. Heavy cable chains were suspended from both port and starboard bow, and held in festoons by means of Manilla ropes to about amidships. Here the cable dropped into the yard, and was coiled to the extent of several fathoms, being ultimately connected with large anchors, which were sunk in the earth. Round the upper hook of the anchor several fathoms of heavy cable were placed. Behind this about 25 tons of cable were placed, and in the rear again about 25 tons of iron girders, built in a box, in order to form a drag. When the ship had left her ways and travelled in the water 20 ft., she was checked by the two anchors in the yard, and when she had dragged these 25 yards further, 50 tons of chain were added to the drag, and at a further distance of 25 ft. another 50 tons of iron in a second box as referred to were brought to bear in the work of checking the steamer. The anchors were dragged 300 ft. before the ship was brought to, but of course the anchors on shore were greatly aided by the two other anchors, which were thrown overboard so soon as the ship was afloat. The *City of Rome* was taken in tow by tug-boats in the Channel, and docked in the Ramsden dock. She was afterwards brought through the Buccleuch dock into the Devonshire dock under the 100-ton crane, where she will receive her boiler engines and other fittings. She is expected to be on her station early in October.

Sir James Ramsden, managing director of the Barrow Shipbuilding Company, presided at the luncheon, at which there were between 200 and 300 guests. He apologized for the absence of the Duke of Devonshire, chairman of the Shipbuilding Company, and then proposed the toast of the day, "Success to the *City of Rome* and the Inman Steamship Company." He referred to the enterprise the Inman Company had shown in ordering the largest steamer in the world, commercially speaking. Mr. Charles Inman, representing the owners, responded, and Mr. Ernest Inman proposed, "The Barrow Shipbuilding Company," to which Mr. J. Fell and Colonel Stanley, M.P., responded. Colonel Stanley said he did not know whether we were going, as Mr. Scott Russell had said, to jump at once to building another Great Eastern, but there was certainly a progressive increase of the size in which ships were being built, and the *City of Rome*, which he hoped would be successful, was the latest instance in point. It may be stated that the Barrow Shipbuilding Company have now on hand two steamers for a French company of 4,000 tons each, two steel steamers for the Peninsular and Oriental Company of 3,600 tons each, two for the Ducal Line of 3,500 tons each, two for the Anchor Line of 3,050 tons each, together with other smaller craft.

It is much to be regretted that a fatal boiler explosion occurred on the *City of Rome* shortly before the launch. The boiler which exploded was a vertical tubular boiler which had been fixed on the deck in connection with a donkey engine for hoisting purposes, and it was not far from the platform which had been erected in the bow of the vessel and on which a number of the invited guests were standing. Fortunately none of these were injured, but four men were killed and six injured.

THE RELATIVE CORROSION OF IRON AND STEEL.*

By Mr. William Parker, Chief Engineer-Surveyor of Lloyd's Register, London.

A FEW weeks ago I had the honour to read a paper before a kindred society—the Institution of Naval Architects—on some peculiarities in the behaviour of steel, which had come under my observation, bearing chiefly upon its qualities of uniformity and ductility. On the present occasion I desire to deal with an entirely different branch of the subject—namely, that relating to its power to withstand corrosion, chiefly in connection with marine boilers and in comparison with iron. When mild steel was first introduced, a few years ago, two questions were prominently discussed; one was its reliability as a constructive material, the other was its durability so far as corrosion, under different conditions of employment, was concerned. The only experience which had been obtained with steel in these directions up to that time was with a different quality of the material to that used in the present day, and it was sufficiently various and contradictory to give rise to much disagreement and no little speculation. This, although it retarded the introduction of mild steel, was in one sense an advantage, for it gave rise to extensive experiments which, while they could not entirely set these questions at rest, at least tended to throw light on the peculiarities of the metal, and hence to lead to its more intelligent manipulation and preservation.

Among the earliest important attempts to deal with the question of corrosion in recent years were the investigations of the late Admiralty Boiler Committee. It is not too much to say that the investigations of that Committee were eagerly looked for by all interested in the subject. The results have been for some time before the public, and have given rise to much discussion. On the surface, they appeared decidedly unfavourable to steel, and deductions have been made from them which are to my mind, open to exception. I have therefore thought that a brief analysis of the methods adopted in conducting the experiments wonld be not only interesting, but that, in view of the prominence accorded to those experiments, it is almost called for at the present time. It will be seen, on looking into the experiments conducted by this committee, that in most of the vertical tubes in which the plates were experimented upon in boiling water (with or without air) there was a copper plate present, and in many instances the different iron and steel plates were held in position by brass or copper rods, while no precautions had been taken to insulate them. Moreover, all the steel plates had been fixed above the iron ones, and as the temperature was greater in the upper than in the lower parts of the tubes, it might have been expected, other things being equal, that the steel would corrode faster than the iron. It could not be said, therefore, that the results of the investigations of the Boiler Committee had settled the question of corrosion, and we were induced to look again to the limited experience that existed, and to the comprehensive experiments made about forty years ago by Mr. Robert Mallet for the British Association. These experiments were on chilled and "green sand" cast irons made by hot and cold blast, or hammered and rolled cast, blister, shear, and spring steels; hammered and rolled wrought iron, including Swedish, Lowmoor, and many ordinary sorts of iron, down to puddled bars.

The value of Mr. Mallet's Paper on these experiments is diminished by the fact that the scale was left on the cast iron in nearly every case, while it is not definitely stated whether it was removed from the wrought iron; but the experiments are nevertheless extremely interesting, and a feature worth notice in them is the appended analyses and densities of some of the materials experimented upon. It may be mentioned that the square plates experimented upon were fixed with their four corners to wooden frames and placed in wooden boxes. The complete results of the experiments will be found in the Transactions of the British Association for the years 1838, 1840, and 1843. The losses by corrosion are given in these tables in grains per square inch, per 732 days, and they can be readily compared with the results of some experiments to be described hereafter, as they are nearly a hundred times greater than if they had been given on the scale I have adopted, which is in pounds per square foot per annum. Comparing the mean losses given by Mr. Mallet of the ordinary sorts of iron with those of Swedish and Lowmoor iron, a difference in favour of the last two is observed when exposed to river-water and to fresh sea-water, while the latter irons compare unfavourably with the common irons when subject to the atmosphere or to what he calls "foul sea-water." The specific gravity stands in close relation to the amount of corrosion, it being found that in all the different classes of material, whether chilled or "green" cast iron, steel, or wrought iron, the heaviest metal of each description lost less than the lightest one. The analyses, of which a full description is appended to the report, show also beyond doubt that the greater the amount of combined carbon (found by combustion), and perhaps silicon, the less was the corrosion. The manganese, which was present in very small quantities, has played such a subordinate part that its effect cannot be traced. These are, so far as I can gather, the principle conclusions to be drawn from Mr. Mallet's paper, although he was of opinion that the finer the quality of the iron the less it will corrode.

---

* Read at the Spring Meeting of the Iron and Steel Institute.

These conclusions, if correct, would be an important addition to our knowledge, but they scarcely accord with the results of experience, and, as I have pointed out, we are at once met by the difficulty that in the case of Mr. Mallet's experiments, we are left in doubt whether the scale was removed or not; and in the case of the boiler committee we are left in doubt how far the want of insulation may have affected the results; and there is the further difficulty in comparing the two sets of experiments, that those of Mr. Mallet were only made in low temperatures and those of the Boiler Committee in high ones. It was shortly after the issue of the first report of the Boiler Committee that I commenced to investigate the subject for the committee of Lloyd's Register of Shipping, and I then endeavoured to arrange the series of experiments I am about to describe so as to avoid as far as possible the sources of error indicated above, and to show the effect of the absence as well as the presence of scale.

In the first place, I obtained twelve discs, 4½ inches diameter, and about ¼ in. thick, from each of the following manufacturers :—

Common iron from the Parkhead Forge Company, Glasgow.
Common iron from the Kerne Ironworks Company, Darlington.
Best quality iron from Lowmoor Iron Company.
" " Bowling Iron Company.
" " Farnley Iron Company.
" " Messrs. Taylor Brothers, Leeds.
" " Leeds Forge Company.
Mild Steel from Landore Steel Company.
" Bolton Iron and Steel Company.
" Messrs. John Brown & Co.
" Steel Company of Scotland.

Six of the discs from each maker were turned bright entirely to remove all scale, and the other six were turned round the edge only, so as to damage the scale as little as possible. Each disc was carefully weighed to $\frac{1}{50000}$ part of its own weight at the Royal Naval College, Greenwich, through the kindness of Professor Reinold. They were divided into six series, each containing twenty-two discs, one black and one bright, from each of the above-named works, and were fixed together by means of an iron rod which had been covered by a glass tube, the plates being separated from each other by means of glass ferrules about ¾ in. long and 1 in. in diameter, thus so far as possible insulating each disc, and preventing galvanic action being set up between them. I may mention that one of these sets of discs as insulated was immersed in sea-water, and it was found that by completing the circuit between any two of them a galvanic current was set up, the bright Lowmoor plate being electro positive to the whole of the other plates; and as it is impossible that the energy represented by the galvanic current could be generated without oxidation or corrosion of the metal, the necessity of thoroughly insulating the discs is evident.

One series (A) was suspended on the roof of a building in the City of London, exposed to the action of the atmosphere, from the 13th February, 1879, to 13th May, 1880, or 455 days. Another set (B) was securely fixed under water to the pier at Brighton from 24th February, 1879, to 7th May, 1880, or 437 days. A third series (C) was so secured to the engine-room floors of a ship trading to the East as to be freely exposed to the action of the bilge water from 9th June, 1879, to 6th February, 1880, or 240 days. The remaining three sets (D, E, and F) were hung up in the wide water-spaces between the tubes of marine boilers in such a manner that they could not swing about, and were always about 12 in. below the water-line. These boilers were each in different vessels, employed in different trades, and subjected to entirely different treatment. The vessel containing series D, belonging to the British India Company, was employed in the East Indian trade; zinc was used in these boilers and they were blown off as seldom as possible. The immersion lasted from the 15th February, 1879, to the 6th June, 1879, and from the 14th June, 1879, to 16th February, 1880, or 361 days.

In the steamer containing set E, owned by the Peninsular and Oriental Company, and engaged in the China trade, no zinc was in the boilers, which were blown out at each terminal port, and run up afresh with salt water. This series was exposed from the 15th February, 1879, to 6th June, 1879, and from 12th June, 1879, to 13th November, 1879, or 64 days. The remaining series (F) was exposed in the boiler of a steam-collier running between Newcastle and London from the 23rd May, 1876, to the 23rd April, 1880, or 336 days. No zinc was used in this boiler, and the water was taken from a point in the Tyne, where it is probable that the refuse from one of the local chemical works acidulates it considerably. The boiler was emptied once in ten weeks, and steam was kept up for four days out of every five. After the completion of the exposure the scale and rust were removed as carefully as possible by scraping and brushing the discs with a file card, and each one was again weighed at the Greenwich College with the same nicety as in the first place, and the results follow in a tabulated form.

(*To be Continued.*)

BOILER INCRUSTATION.

THE dangers and waste of fuel arising from the formation of Scale in Steam Boilers, are doubtless too well known to our readers to render necessary their recapitulation here; we may, however, refer to the annual reports of the Steam Boiler Insurance Companies, which contain collective evidence of the disastrous results to life and property, where scale or deposit is allowed to accumulate,* to say nothing of the waste of fuel and time lost in getting up steam. Some idea may be formed as to these last two items, from the fact that carefully conducted experiments show that even with a thin deposit of only $\frac{1}{16}$ of an inch, the presence of such an intervening non-conducting material between the boiler plates and the water, gives an average loss of 10 per cent in fuel. Now, of remedial agents proposed and introduced for the abatement of this great source of trouble to Steam users, the number indeed is almost "*legion*"; the subject is therefore one which we touch upon with extreme caution. Unfortunately many of the so called "remedies," which have been introduced and are still in the market, are mere quack specifics, launched by adventurers who are devoid of any practical knowledge of the important subject to be dealt with: we find too, that the circulars of several of these "nostrums" have the imposing prefix "Patent" unblushingly added, without a tittle of right to assume the privilege inferred by the use of that word. Not only so, but, in many cases "Boiler Fluids" or "Anti-Incrustators" are not only ineffectual, but positively injurious. We hold with the wholesome maxim, that "prevention is better than cure," and, that wherever a system of filtration or depositing can be adopted (such for instance as the process of the late Dr. Clarke, and more recently that known as the Porter-Clarke process,) this is preferable to "doctoring" the boiler. In many cases, however, there is no alternative but either to allow the deposit and formation of incrustation to go on until an opportunity occurs to scale or chip the boiler, or else to apply an antidote. A really good anti-incrustation composition being therefore a desideratum, we have been induced to enquire into the merits and actual results obtained by the use of a composition for this purpose which has been recently brought under our notice, namely, that manufactured, and supplied as a fluid, by Messrs. W. Allen & Co., of the Canteen Works, Vicarage Lane, Stratford, E., and which we find to be such as to justify our referring to here, especially as Messrs. Allen have evidently given the important subject of boiler incrustation most careful and exhaustive attention: they do not profess to prescribe an all round system of treatment, but, on learning the actual conditions as regards the nature of the deposit, the kind of water used, &c., they are prepared to guarantee a successful result for their remedy if used in accordance with their directions to meet the requirements of the case. Briefly, all that Messrs. Allen ask for, is a fair opportunity to demonstrate the efficiency of their invention, and to which therefore, we have pleasure in drawing the attention of our readers.

A NEW Iron Shipbuilding Company is about to be established at Blyth. Two large iron steamers are now building on the Tyne for an Italian firm.

---

* We may specialize the valuable report of the Chief Engineer of the National Boiler Insurance Company for last year, which details instances of fracture and fatal explosions arising from such deposits.—ED. M.E.

THE INFLUENCE OF CUT-OFF AND LENGTH OF CONNECTING ROD ON THE WORKING OF STEAM-ENGINES.

By C. E. Stromeyer, Esq., Engineer Surveyor to Lloyd's Register.

[Read at the Twenty-Second Session of the Institution of Naval Architects, 7th April, 1881; the Right Hon. the Earl of Ravensworth, President, in the Chair.]

(*Continued from page* 58.)

If you imagine a turning moment to be acting on a weightless shaft to which a fly-wheel having a moment of inertia T has been fixed, it will produce an angular acceleration.

$$\theta = \frac{M}{T}.$$

If the same moment is made to act on a weightless crank shaft to which a connecting rod and piston having the combined mass (m) has been connected, it will produce a downward acceleration

$$\frac{M.}{m \, . \, r \, . \sin \alpha}$$

and an angular one

$$\theta_1 = \frac{M}{m \, . \, r^2 \sin \alpha^2}.$$

If θ and θ_1 are to be equal, then T must equal $m\,r^2 \sin \alpha^2$. By substituting the masses of piston and rods for the different engines, in equations showing the angular acceleration of a crank at any time or angle, the following equations will be the result: T_1 T_{11} and T_{111} are the inertia of imaginary fly-wheels—

Single Engine $$T_1 = r^2 \left[\left(m - \frac{I}{l^2} \right) \sin \alpha^2 + \frac{I}{l^2} \right].$$

Double Engine $$T_{11} = r^2 \left[\left(m_1 - \frac{I_1}{l_2} \right) \sin \alpha^2 + \left(m^2 - \frac{I^2}{l} \right) \cos \alpha^2 + \frac{I_1}{l^2} + \frac{I_2}{l^2} \right].$$

Treble Engines $$T_{111} = \left[\left(m_1 - \frac{I_1}{l^2} \right) \sin \alpha^2 + \left(m_2 - \frac{I_2}{l^2} + m_3 - \frac{I_3}{l^2} \right) \frac{1}{2} \cos \alpha^2 - \left(m_2 - \frac{I_2}{l^2} - m_3 + \frac{I_3}{l^2} \right) \sqrt{\frac{3}{4}} \cos \alpha . \sin \alpha + \frac{1}{4} (m_2 + m_3) + \frac{I_1}{l^2} + \frac{3}{4} \frac{I_2 + I_3}{l^2} \right].$$

If $m_1 = m_2 = m_3$ as before, then—

$$T_{11} = r^2 \left(m + \frac{I}{l^2} \right),$$

$$T_{111} = r^2 \frac{3}{2} \left(m + \frac{I}{l^2} \right).$$

which can be expressed as follows:—In double and treble engines the oscillating masses, if equal, act in the same way as a solid fly-wheel of an equal total weight, and having for diameter the length of the stroke. In single engines only a very small part of the total masses act as a fly-wheel. Therefore, the following tables, which have been compiled on the assumption that the oscillating masses produce no disturbing influences, will only be strictly applicable to the case of double and treble engines where the weights of the pistons and rods of the different engines are about equal, though they will no doubt be found of value in some of the other cases. The values were arrived at in the following manner: Let ψ represent the ratio of greatest increase or decrease of energy to the amount of work indicated per stroke, and η the coefficient of uniformity, then

$$\eta = \frac{\psi \times \text{work per stroke}}{T \times \omega^2},$$

and the inertia of fly-wheel $T = \frac{\psi}{\eta \, . \, n^3} \times 1{,}500{,}000 \times \text{I H P}.$

where n = number of revolutions per minute, η and every other value except ψ is known; to find this a great number of diagrams representing the turning moments of single, double, and treble engines, with six different grades of expansion and eleven different lengths of connecting rods, were drawn according to the following formula:—

$$\frac{d\,u}{d\,x} = h \left(1 + \frac{y}{x} \right),$$

$$M = P \, . \frac{d\,u}{d\,a} = P \, . \, h \left(1 + \frac{y}{x} \right).$$

Then the line of mean resistance was drawn through them, all the different areas above and below this line were measured, and the largest one divided by the area during one half-revolution, which is the required co-efficient ψ. To find Q, the weight of the fly-wheel, substitute the proper value of ψ out of the table into the following formula, where R = radius of fly-wheel and η co-efficient of uniformity.

$$Q_1 \text{ tons} = \frac{\psi}{\eta\, n^3} \times \frac{\text{I H P}}{R^2} \times 21600.$$

The weight of a solid fly-wheel is

$$Q_2 \text{ tons} = \frac{\psi}{\eta\, n^3} \times \frac{\text{I H P}}{s^2} \times 174400.$$

If, however, in a double or treble engine Q is equal to or less than the total weight of the pistons and rods, then no fly-wheel is necessary.

Looking at the Diagrams II., III., IV., of the value ψ which gives one an idea of the necessary weight of fly-wheel or revolving masses, it will be seen how very much smaller it is for the treble than for the double and single engines, and that it does not vary, as has been generally assumed, inversely as the grade of expansion, but that it increases at the same rate as the length of stroke while the connecting rod remains constant. In Diagram V. you will notice that the values diminish between the lines, representing a cut-off of about $\frac{1}{10}$ to $\frac{3}{10}$ stroke. This depression puzzled me greatly at first, but I found on looking at the diagrams that for the above cut-offs the maximum turning moment of one engine is exerted just when one of the other cranks is either at the top or bottom of stroke: the result is a very uniform diagram. The same thing occurs in double engines for a cut off of about $\frac{7}{10}$ stroke, which will explain the depression in Diagram IV. Looking at Diagrams IV. and V. it will be seen that the co-efficients of a double or treble engine, in which the ratio of $l : s$ is 1 : 1 and 2 : 1 respectively, are nearly identical for grades of expansion varying from $\frac{3}{10}$ to $\frac{6}{10}$, and that beyond these limits the treble engine has the advantage; it therefore appears strange that, except for centrifugal pumps, the three-cylinder engines which are now being constructed should have what appear to be long connecting-rods, especially as by lengthening the stroke at the expense of the diameter and other dimensions, the friction in the bottom end is reduced considerably.

In conclusion, I wish to say that as all the diagrams on which the calculations were based are theoretical ones, the results will never be absolutely in accordance with practice, but they give a very good idea of the influence of the two dimensions often referred to above, and will, I trust, facilitate the work of those who now and again have to go into this subject for new types of engines. Rounding off the corners of the diagrams will have the effect of levelling the lines, *i.e.*, increasing the small co-efficients and diminishing the large ones.

Summing up the results of all these calculations you obtain a few rough formulæ.

Weight of a solid fly-wheel the diameter of which equals the length of the stroke is Q.

Single Engines $$Q_1 = \text{I H P} \times \frac{75000}{\eta\, s^2 n^3} \left(.30 + \frac{s}{7\,l} - \frac{e}{10} \right)$$

Double Engines $$Q_2 = \text{I H P} \times \frac{75000}{\eta\, s^2 n^3} \left(.07 + \frac{s}{8\,l} - \frac{e}{8} \right)$$

Treble Engines $$Q_3 = \text{I H P} \times \frac{75000}{\eta\, s^2 n^3} \left(.055 \times \frac{s}{20\,l} - \frac{e}{20} \right)$$

$$\frac{s^2\, Q \times 2240}{8 \times 32{\cdot}2} = T.$$

The friction is approximately

Guide friction $= Fg = \text{I.HP.} \times \psi \times \frac{s}{l} \times {\cdot}40$

Crank or journal friction $= Fc. = \text{I.HP.} \times \psi \times \frac{d}{s} \times 1{\cdot}6$

Explanation of Tables and Diagrams I. and II.

To find the loss due to guide friction, multiply the values in Tables I. *a* or I. *b* by $\phi \times$ IHP.

To find the loss due to crank-pin friction, multiply the values in Tables II. *a* or II. *b* by $\phi \frac{d}{s} \times$ IHP. × 1·57.

ϕ = Co-efficient of friction. **d = Diameter of crank-pin or shaft.**

s = Length of stroke. **IHP. = Indicated horse-power.**

The lines marked △ give the values for triangular diagrams.

RATIO OF MAXIMUM INCREASE OF ENERGY TO INDICATED WORK PER STROKE.

Explanation of Tables and Diagrams III., IV., V.

To find the inertia in foot pounds of the revolving masses of an engine necessary to hinder the speed from varying beyond certain limits of the average speed, multiply the value in the tables by $\frac{\text{IHP.} \times 1{,}500{,}000}{\eta\, n^3}$.

To find the weight of a fly-wheel in tons which will produce the same effect, multiply the values in the tables by $\frac{\text{IHP.} \times 21600}{\eta\, n^3\, R^2}$

η=Co-efficient of uniformity=$\frac{\text{maximum speed—minimum speed}}{\text{mean speed}}$.

n=Number of revolutions per minute. R=Radius of Flywheel. IHP.=Indicated horse-power.

MILD STEEL IN FRENCH ARSENALS.

On the Use of Mild Steel for the Construction of the Hulls of Ships in the Arsenals of the French Navy.

By M. Marc Berrier Fontaine, Member.

(*Continued from page* 56.)

SUCH a divergence of opinion, which moreover, I am assured, is to be found also on the other side of the Channel, appears to me to be one of the best proofs possible of the almost perfect equality of the two rival processes. For if the superiority of produce obtained by either of them was undoubted and constant, it could hardly fail to have been long ago recognized by the constructors, who have to work up the steel obtained, and by the manufacturers themselves, who have not, as a general rule, any particular interest in either of the two processes mentioned, seeing that they habitually use them side by side. The daily increasing homogeneity of the plates and moulded bars which are used in our dockyards does not seem to me, nevertheless, the only cause of the increasingly satisfactory results obtained in the various processes to which these materials are submitted in the yards. Our experience tends to prove, in fact, that the increasing familiarity of the workmen employed in these processes, particularly upon those plates and bars which are worked hot, has had at least an equal share in bringing about this fortunate result. Greater practice in using the new material, and increasing familiarity with it, if I may use such an expression, a more thorough knowledge of its qualities and of its defects—of its strong and of its weak points—in a word, of its behaviour and of the special management which it requires, so as not to produce failures, and even the confidence which is gradually showing itself in their treatment of it, are all causes tending strongly to the same end. I have several times, for example, had to remark that it is not generally the workmen having most experience in skill in working iron who manage most quickly to understand the working of steel in the most satisfactory manner. Although this fact may seem paradoxical at first sight, there is nothing in it which ought really to surprise us, for skilful workmen, accustomed for many years to certain processes of work, and to certain tricks of hand which they have always found succeed, and having, moreover, complete confidence in themselves, without reflecting that a metal which does not differ from iron in external appearance can possibly have different properties, will naturally treat it in the same manner.

It is thus only after repeated failures that they become convinced that the new metal has a different behaviour from that of iron. It is still later that they come to admit that this new metal, provided it is treated by them with a certain special management, is, taking it all in all, more manageable than iron, and able to bear without danger abrupt bending which iron will not bear even when of exceptionally good quality. The younger workmen, on the contrary, have less settled habits, and at the same time they have less confidence in their own skill, and thus are more ready to conform with docility to the advice given them and the instructions which they receive; in a word, they have not got to unlearn anything, as is the case with their older and more skilful fellow-workmen. Consequently, when they are clever and intelligent, they are the first to understand how to work steel as it ought to be worked. If, for instance, they have to submit a piece of steel to rather trying treatment which cannot be completely finished before its temperature falls below a dull red, workmen skilled in handling iron will be disposed, even, according to their notion, in their employer's interest, to continue their work at a black heat, because they know that a similar piece of iron would not suffer from this, and before having gone through a fresh apprenticeship they cannot realize, however often they may be told of it, that a similar piece of steel will not behave itself in exactly the same manner. The younger workmen, especially those who have not learned to work in iron before working in steel, are naturally free from these prejudices and from this instinctive resistance to the advice given them, they will not hesitate to stop their work at once as soon as it cools to a dull red, and to return the work to the furnace or the forge to give it the fresh heat that is sufficient in many cases to avoid the defects and injuries which their older and more experienced companions consequently find they have to pay for more often than their younger fellow-workmen. It is hardly necessary to add that the more skilful of the iron workmen, as a rule, very quickly pick up the distance which their younger fellow workmen who had fewer traditions to unlearn were able to gain over them in working the new metal. After some months it is found that the balance is restored and that the old skilled workmen have again taken the first place, which they had only momentarily lost. The best workmen for iron are then found to be also the best for steel, and in fact they soon take so kindly to the new metal that they would look with contempt upon a proposal to return to working in iron, a remark which has been very justly made by Mr. W. Denny in his very interesting communication "On Steel in the Shipbuilding Yard," read by him last year before this Institution.*

It seemed to me that it might be interesting to go into some detail respecting this cause of the steady and progressive improvement of the results obtained in working steel, because it has not until now, so far as I am aware, been pointed out by anybody, although it has several times been brought under our notice in the most striking manner, especially during the first months in which the use of steel was largely developed in our dockyards. I will quote what I consider a very conclusive example of the influence of this cause. The frame of the *Foudroyant* behind the armour-plating is formed of H or double tee-bars of 300×148×14 mm. (Fig. 1, Diagram 1.), which being cleft at their two ends had to be bent into the shape represented on Diagram II., Figs. 1, 2, and 3, the curve of the upper half having to be joined to a similar curve in the corresponding deck-beam formed by a double tee-bar of the same scantling. This has always been attained without any difficulty, which might very well be, seeing that by the continuous character of the curvature in question the strain to which this end of the piece of work was exposed was evidently less severe than the forge test required before the same bars could be received, a test in which half of the bar has to be, not bent out upon a continuous curvature, but sharply bent, and almost folded at its stem, being kept straight for the rest of its length. The lower half of the bar was in quite a different case, having to bear a much severer trial than that of the receiving test,† one-half of the bar having to be bent at a right angle with a joining curve of a very small radius. Again, among the first bars which had to be submitted to this trial there was a considerable proportion which could not bear it, the extension of the curved part taking place all at once on the very short length of one side or the other of the point of greatest curvature, marked A upon the figures, the thickness of the web being thus suddenly reduced at this point A, and it frequently cracked. A considerable number of bars had to be returned for this cause.

When, however, we heard that the frames of the *Devastation*, a ship built from the same drawings as the *L'Orient*, had perfectly well borne this same work, we were naturally induced to suppose that our failure at Toulon was due to an inferior quality in the double tee-bars which had been delivered to us. Further experience, however, very soon convinced us that it was not so. The proportion of damaged pieces began steadily to diminish, and we soon came to have to reject none. It was not possible to attribute this improvement in the results to any corresponding improvement in the quality or homogeneity of the metal, since the whole of the bars necessary for the frames of the *Foudroyant* had been turned out from the same works and delivered together. It could have in reality no other cause than the improvement in the processes of work necessary to mould the different pieces mentioned, an improvement entirely due to the greater practice the workmen had obtained in getting them into shape. It seemed to be all the more necessary to insist on the extent of the influence which increasing practice and skill on the part of the workmen could have upon the results obtained, in that the ship constructors, who have only recently begun to make use of steel, and who have not yet got out of the period of failure due to the fact that the apprenticeship of their workmen is not yet finished, will find in this a reason for not being discouraged; when they know that their predecessors have had to go through the same trials and pass through the same ordeal of mistakes, but nevertheless succeeded pretty quickly in shaking off these small troubles as soon as their workmen had obtained sufficient experience of them, they will be more disposed to persevere. I think, therefore, that I am rendering a real service in persuading them to continue the use of a metal, the superiority of which they will not fail soon to appreciate, although they may still entertain some doubts about its qualities.

There is a third cause whose influence in the improvement of the results obtained in working steel acts favourably for us. I mean the successive improvements which have been already introduced, and are being daily introduced, in the stock of tools in our shops. The new metal requires to be treated with much more care and management than iron. It will not bear, without suffering from it more or less, violent blows from iron hammers, or the irregular tears produced by using hand chisels. All the improvements in tools which can save us from having recourse to such blows and faults, and all those whose effect is to hurry the work on the plate while hot and to secure its being finished before the temperature of the stuff has fallen below the dangerous limit of dark red heat; all these improvements in our tools, I say, cannot fail to contribute most effectively to the perfection of finish of the work. As examples of the most important improvements in tools that I mean, I may point out the following: For the hot bending of plates, the replacing of furnace heat, which was formerly used, by gas ovens in which the plates and moulded bars can be raised to higher and more uniform temperature, has had for one of its results great economy of time and money, since the use of these new furnaces has enabled us to reduce in many cases the number of heats, and has given us much greater facility in carrying through the work itself; because the metal, being thus more strongly and uniformly heated, becomes much more malleable and ductile, and yields much more easily to all the changes of form to which it is subjected.

---

* Transactions Institution of Naval Architects, vol xxi., 1880, page 188.

† See the conditions of this test, Appendix A.

The already long experience of the works of Lorient, where ovens on the Siemens system were in use from the beginning, has been fully confirmed on this point by the experience of the works at Toulon, where ovens on the Gorman system have been preferred on account of their great simplicity of construction and management. These last ovens have been already at work for five years very satisfactorily, this result having been secured in great part by certain important changes in the position of their gas producers which experience has forced upon us.

The use of methods of mechanical traction, securing a high and steady speed without any sudden variations, as been developed as much as possible both for drawing the hot metal from the ovens and taking the work without loss of time to the points at which it is to be worked, and also for getting it into shape in a progressive manner without jar or shock. At Toulon we use for all work of this description two capstans driven by small hydraulic engines on Brotherhood's system, and also return pulleys suitably arranged to control all the movements of the waggons running upon trams inside the workshop. As soon as a piece of metal is brought to a fitting temperature, it is seized in the oven by pincers, to which a cord is made fast, which, passing over other return pulleys, passes to one of the two capstans. A workman starts it by pressing his foot on a lever close to the ground; a few turns, occupying only a few seconds of time, are enough to get the piece thus drawn on the plates alongside of the guides upon which it is to be moulded; one of its ends being quickly fitted against these guides, the other end is clutched by a claw which is hauled upon by a cord seized upon one of the capstans; with a few turns of this capstan, which again only takes up a few seconds of time, the piece of work is brought to the necessary curvature steadily, without any sudden shock or jar, consequently without injury, and at a heat at which it still retains all its malleability. While the capstan thus does the chief part of the work, the hammermen have only got to set right the parts which tend to start or buckle. Treated in this way, it can be so rapidly brought into its final shape that it is still red when the work is finished, and the heat which it still retains is amply sufficient to anneal it without its being necessary to give it a fresh heat for the purpose.

The substitution of wooden swages and mallets for iron swages and hammers, which formerly were in almost exclusive use for working plates and moulded bars, is a great improvement, although one which it has been most difficult to get the workmen to adopt. They assert, not without some reason, that even with equal weights they cannot obtain with wooden mallets, which are not so hard and which suffer compression, such strong and effective blows as those with iron hammers, which act upon a smaller extent of surface; but it is exactly these very strong pressures brought by iron hammers upon a limited portion of surface which tend to produce permanent local injury, these injuries being perfectly visible and due to the metal being crushed and tempered (so to speak) in a little ring, corresponding to each blow of the hammer, without its having, as a consequence, lost any appreciable part of its homogeneity. We therefore insist in our workshops on the use of swages and mallets of wood for working steel in all cases in which the shapes to be obtained are too abrupt in form to render their use impossible. Experience has, moreover, shown us that good workmen quickly get to bend all plates of ordinary curvature, using exclusively wooden swages and mallets, and that they are only obliged to use iron swages or hammers for plates of exceptionally sharp curvature. In these exceptional cases, it is necessary to be very careful to see that the work which has been subjected to such violence is carefully annealed afterwards. The iron pins and rings which are ordinarily used for moulding on the bending floors, the curves to which the bars have to be wrought, have, when steel bars are concerned, the great inconvenience of presenting but a very small bearing surface on account of their small diameters, the result of which is that these pins often give a local nip to the plate pressed against them, which produces a more or less deep impression on the edge of the plate, or at any rate a bend, in consequence of which the curvature of the edge ceases to be regular.

To avoid these inconveniences it became a practice to trace the mould, not directly by the help of pins and rings, but by a strip of plate previously bent to the proper mould and resting against the pins.* The exchange of these pins and rings of small diameter for drums of cast iron of considerable diameter has allowed us to abandon the use of these aligning strips. The very useful introduction of these cast iron drums, bored to receive the pin which fixes each of them to the bending floor, with a series of holes spirally arranged at progressively increasing distances from the outer circumference, was, I believe, introduced by Mr. Denny. It was at any rate at their works that I first noticed these discs. They have been introduced since into the tool supply of the Toulon Works, where they have given perfect satisfaction. We also regard as a marked improvement the substitution of the progressive and steady pressure of hydraulic presses for the sharp and violent jar of steam hammers for all work taking strong curvatures or sharp changes of form. Thus the very extensive development of water-pressure machines allows us at the present day to obtain with great facility clubbed ends, quoted as examples by M. Barba † as well as a great number of pieces of similar work, punched, clubbed, or moulded to sharp curvatures. Some examples of pieces of work thus obtained are represented on Diagram II., Figs. 4 to 8. So again, water pressure has been used with complete success in forming garboard strakes and other plates. In all such cases the action of hydraulic presses, while quite sufficiently rapid, is so steady that it is seldom necessary to anneal the work subjected to it. The use of steady and progressive pressure is, moreover, at least as useful in the work done cold as in that which is done hot. So again the use of hydraulic presses gives the most satisfactory results when applied to the work of fitting and moulding angles or other work with sufficiently open curvature to admit of their being done cold. This is the case with all the deck beams as well as for the greater part of the angles of the longitudinal stringers, and also for a very large proportion of the angles of the frames. At Toulon this work is performed by presses of graduated power from 5 to 100 tons, some vertical, some horizontal, to suit all possible cases. One press of 100 tons is quite sufficient for the straining and moulding of double T-bars of iron of 350 mm. × 150 mm. × 15 mm., and of steel bars of 300 mm. × 148 mm. × 14 mm., Fig. 1, Diagram I. The profiles of these are among the most rigid forms of all those with which we have yet had to deal. A press of 50 tons is sufficient for the straightening and moulding of almost all the other forms that we use, from that of H or double T-bars of steel of 250 mm. × 10 mm, 130 mm, Fig. 2, diagram I. Finally, the small 10-ton presses can easily mould steel angles of 150 mm. × 150 mm. × 15mm., and 5-ton presses will mould steel angles of 120 mm. × 120 mm. × 12 mm. I do not think at this time of day it is necessary for me to discuss at length the advantage that we find in the use of hydraulic machines of other types which we possess in our assortment of tools at our plate-working shop, which is completely fitted with machines on this system, because the advantages which it offers are not special to working plates and moulding bars of steel, but are equally useful for the same work in iron.

These advantages, moreover, have been fully explained and discussed by me in a separate paper read by me three years ago at a meeting of the Institution of Mechanical Engineers in Paris.‡ I cannot, however, pass over without remark the smoothness of work of the hydraulic machines for punching and shearing, the complete absence of jar or jerk in the speed of the tool at the moment that the tool comes into contact with the work to be punched or sheared. These are very advantageous conditions for working on steel which has to be treated with all possible care. Although it has not yet been possible for me to undertake precise comparative trials on this subject, it seems to me to be very nearly certain that the action of punches or shears worked by hydraulic pressure must upset very much less the edges of the holes or cuts made in the steel plates with consequently less damage to their uniformity than would arise from the use of a punch or shears driven by mechanical transmitters of motion, in which the tool always reaches the work with a considerable speed, the work being consequently exposed to more or less jar or jerk.

If, as seems to have been established by the comparative trials,

MILD STEEL IN FRENCH ARSENALS—Diagram II.

of which the results were communicated in 1878 to this Institution and to the Iron and Steel Institute, the mere substitution of a punch with a helix for its cutting edge, which is thus brought to bear progressively on the consecutive portions of the circumference of the hole to be made (Kennedy's patent spiral punch), for the ordinary punch of which the cutting edge is in a horizontal plane, and is brought to bear all at once on the whole of the circumference; if, I say, this simple change is sufficient to insure that the metal shall be less upset on the edge of the hole, we must also admit without hesitation that the greater smoothness of action of hydraulic punches and shears, must have just as favourable an effect, and that the introduction of these machines must consequently tend to render less necessary the annealing process to which it is still considered desirable to subject plates and moulded bars in steel after they have been punched or sheared. Again, with the object of avoiding for steel all useless "punishment," we take great care to rid ourselves of all processes which crack or upset more or less deeply the edges of the plates or the ends of moulded bars, and which leave more or less irregular burrs. As Mr. Barnaby has very justly said, in a communication "On the Use of Steel in Naval Construction," read in 1879 before the Iron and Steel Institute," When the end of a bar of iron is cut off roughly, and is left ragged, the layers break off suddenly if struck heavily, whereas the other end of the same bar trimmed off evenly will bear heavy swaging without rupture. The one end behaves far better than common iron would, the other far worse."

These considerations have led us to forbid absolutely the use of the punch for making cuts in the plates, whether straight or curved by a string of holes. In that respect again the exceptionally large stretch of our hydraulic shears, which is uniformly of 1·50 metre, or 5 feet, gives us a great advantage, for it allows us to shear the largest plates in any direction whatever, and to cut sheets of any length whatever up to 3 metres wide straight across. As regards curved cuts, we obtain them at once by means of a series of blades having graduated curvature, and brought sufficiently close to one another for them to cut out with sufficient exactness all shapes which can occur, whatever be their curvature. A collection of bent blades of this kind makes an outfit which is extremely valuable and quite new as I think. I can give you no better idea of the shape of these blades than by saying that we can suppose them to be obtained by rolling the flat blades of a shearing machine on cylinders of selected radius, without altering the length of the blades or the inclination of their cutting edges; for curves of large radius the blades thus moulded can only give greater or less proportions of the circumference of a circle, and several cuts are necessary to make a complete circle. If, on the other hand, the curvatures that one wishes to obtain are sufficiently marked for the corresponding perimeters to be less than the length of the rectilinear blades, the bent blades really form large punches, which can cut holes of very great diameters at one stroke. I may mention, by way of example, that some of our shearing machines had been designed for cutting in a straight line at each cut a length of 65 centimetres. For circular curves of less than 10 centimetres radius, these blades become closed cylinders, which permit us to punch with one stroke circular openings of 20 centimetres diameter. I would remark that if these closed blades had been actually obtained from rectilinear blades belonging to the same machines, by rolling the latter upon cylinders of suitable diameters, they would give, as in fact Kennedy's spiral punch does give, a sharp step, with its riser following the generating line of the cylindrical surface, upon which the two extremes of the rolled-up blade would lie (Fig. 11, Diagram II.). In order to avoid this inconvenience which would weaken the blades and make it more difficult to support them, while still retaining the screw-shape for the cutting edge of all these open blades (Fig. 10), we give up this form for the closed cutters, and substitute for it in this case the elliptical form (Fig. 12), obtained by intersecting the cylindrical surface for the cutter by an inclined plane.

I would finally point out, before leaving this subject, that the extension of the same principles has enabled us to adapt to our shearing and chiselling machines blades with two cutting edges (Fig. 13), used principally for splitting without distortion the ends of bars which have to be more or less open to the end; the slope of these blades with two cutters is made equal to twice that of simple shears of the same machines. Or we may adapt to them a set of multiple punches, coming into play successively, which allows us to make both rapidly and economically the holes in deck plates (Fig. 14), and ventilating holes as well as bulkheads (Fig. 15, Diagram II.). The use of circular saws and of endless saws which can cut steel cold, are equally useful to us for cutting off moulded steel bars, and strictly speaking trough iron cannot be cut with shears. In order to cut off or finish the ends of the great part of these bars it was formerly necessary to use either planing machines, the work of which was extremely slow and expensive, or to employ workmen with chisels and hand-hammers, of which the violent and repeated blows considerably upset the ends of the bars. By means o sawing cold we can, on the contrary,

MILD STEEL IN FRENCH ARSENALS—Diagram I.

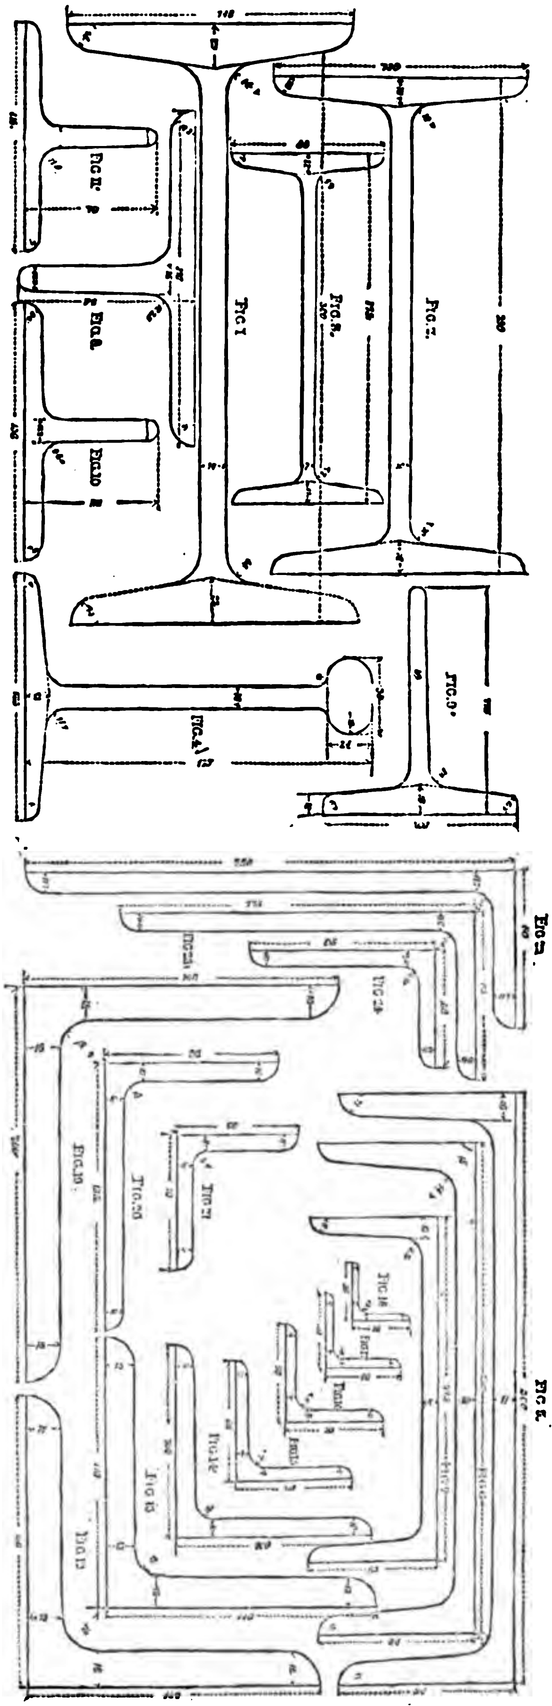
SCALE ½ NATURAL SIZE



N.B. The Weights marked on the Sections are in kilogrammes per metre run.

cut right across or in oblique directions bars of all sections perfectly clean and sharp without in any way upsetting the ends of the bars, and without its being found necessary to anneal them after the work is finished. I think we may say generally that the tools which carry out the most exactly the work which we have to do, whatever it may be, are at the same time those which least upset the neighbouring portions of the pieces of work upon which they act. It is with a view of carrying this principle into practice that we do not hesitate, whenever it does not appear to us absolutely impossible to do so, to replace hand-tools, the work of which is always irregular and more or less coarse, by machine work, which, on the contrary, is always steady, regular and uniform. We attach, moreover, particular importance in all our tools, of whatever nature they may be, to using nothing but steel of the best mark and of most carefully selected quality, however much higher the price may be. We at the same time take care that the working angles of these different tools should be set as may be most suitable for each kind of work.

Finally, we require that the most rigorous and the most unceasing attention should be given by the foremen and by the workmen themselves to seeing that the cutting edges of their tools should always be kept in the most perfect condition. In order to secure as far as can be this last requirement, we have been induced to develop very largely the employment of grinding machines, with artificial emery grindstones specially arranged for setting the tools of various forms, these machines allowing us to obtain a regularity and a precision of edge which it would be impossible to obtain by hand. These artificial emery grindstones are also very useful for the work of taking off burrs, and finishing both plate work or moulded bars, as well as in finishing the small forge pieces, such as ringbolts, staples, hinges, and so forth, which form so large a part of modern construction. Formerly these things could only be executed with the file and chisel, which gives much less satisfactory and more costly work. It will be impossible for me, without exceeding the limits of time imposed upon me, to go into the complete detail of the saving which we have been able to obtain through the improvements in the tools, among which I thought it right to point out, as above, a certain number of the most important. I will therefore confine myself, in order to give an idea of the importance of the saving which we have thus been able to realize, to quoting a single example. The comparative trials, made with the greatest care and prolonged through several months, have put us in a position to assure ourselves with perfect certainty that the simple replacement of the flat-ended dies which, until then, had been exclusively used for our punching work by twist drills of the best quality set with mathematical precision by the help of a small special machine with an emery wheel, has permitted us to effect, in the execution of work of this nature, a saving of very nearly one quarter (exactly 22 per cent.)

I have endeavoured to show in what goes before that three principal causes have mainly contributed, and still contribute every day, to the constant and progressive improvement of the results obtained in working plates and moulded bars in steel, of which the framework of our ships now almost exclusively consists. This improvement has, moreover, led the constructors of the French Navy to the same conclusion as their colleagues in the British Admiralty; the possibility, and even the desirability, of relaxing by slow degrees, but steadily, and continually more and more, the severe requirements which had at first been imposed by them for the execution of work of every description to which the plates and moulded bars of steel should be submitted in the dockyards. We have already been able to introduce numerous and very important relaxations in the extremely rigorous and expensive precautions which had been recommended by the French constructors in 1874, and specified as absolutely necessary by the English constructors up to as recent a date as the year 1879.[*] It thus happens that the cases in which it is judged necessary to anneal steel plates and moulded bars are now incomparably less frequent than they used to be a few years ago, and the number is still undergoing daily reduction. Thus also it happens that we are returning by degrees to the use of the simple punch, without annealing and without riming, for cutting holes in almost all the pieces of framework of the new constructions, reserving the use of the drill for those pieces only in which there is special reason for keeping up the greatest possible strength, having regard to the more important position that they have to take in the construction, or the exceptional strains they may have to bear. It is worth while, moreover, to remark that the very rigorous precautions to which the constructors were obliged to confine themselves as a matter of principle, when they began to make use of plates and moulded bars of steel, were principally—I might almost say wholly—intended to meet the local want of homogeneity resulting from the strains more or less violent which the work had to undergo in the workshops, and that the precautions in question were directed beyond everything to prevent those singular breakages which then used to be common enough, and which gave besides all the more anxiety because their true causes had not yet been completely ascertained. If the constructors had not been influenced by the fear of seeing at every instant, and without apparent reason, such accidents produced, the exceptional precautions would have been set aside much sooner, and they would, consequently, long ago have submitted to the small loss of strength produced by the various manipulations through which these steel plates and moulded bars have to pass; just as, for instance, they have always accepted, without any difficulty, the corresponding loss of strength which plates and moulded bars of iron have to undergo. The most recent trials appear to prove that the loss of strength in question is not much greater in these cases for steel than for iron. It seems no me, therefore, to be beyond doubt that at no distant period—as soon as the breakage of steelwork becomes sufficiently rare not to require greater precautions in working these pieces than those which are applied to iron, that is to say—we shall very soon get into the way of punching nearly all the steel plates and moulded bars, and of only annealing them in exceptional cases, when they may have been submitted to very violent and very trying deformations; a treatment, in fact, precisely similar to what we give to iron under the same circumstances. Notwithstanding the very considerable relaxations which have been introduced into the precautions which had been thought necessary at first, the proportion of fractures which occur in working steel plates and bars (fractures of which a minutely exact account has been kept) has been steadily diminishing, and is now reduced to a very low proportion.

I have collected with a few unimportant omissions, the results obtained in this respect in the works of the five principal French dockyards and in those of the Société des Forges et Chantiers de la Méditerranée, at La Seyne, near Toulon, from the time at which steel was first introduced on a large scale up to the end of last year. The figures show that the proportion of fractures which occur in working steel has now become extremely small. As has been well remarked by Mr. W Denny,[*] if we were to take as careful account of the corresponding accidents which occur in working plates and bars of iron, we should probably be very much surprised to have to admit that the frequency of accidents of this nature is, in proportion to the total weight of the material used, at least as great, and perchance even greater, for iron than for steel.

I will only mention briefly a fact which proves to what extent the results obtained in working steel are still capable of improvement accordingly as the quality of this metal bcomes more and more satisfactory, and as the workmen who have to deal with it get accustomed to treat it by the processes which suit it best. It cannot be denied that only a few years ago the constructors considered weldings of plates and bars of steel as difficult to execute in a thoroughly satisfactory manner. At L'Orient it was the practice to effect these weldings by putting an iron liner,[†] between the two surfaces of steel which were to be welded together. When it was necessary to use angle irons with sharp angles more or less departing from a right angle, the practice of the same workshop was not to cut the portion which had to be kept flat, so as to avoid the necessity of having afterwards to weld it. They confined themselves, therefore, to arranging the work so as completely to flatten down this part. This was a very long and expensive process. In other workshops the foremen smiths, in order to effect the welding of steel, had recourse to the use of mixtures of very curious character, and containing the most extraordinary materials. Thanks to the more complete homogeneity and ductility of the steels which are now delivered by the manufacturers, thanks also to the increased practice which our workmen have acquired with the new metal, the welding of steel plates and bars can now be effected as easily, as simply, and as satisfactorily as that of similar work in iron, without its being necessary to have recourse to any special process or to the use of any particular flux. A great number of weldings of steel plates and angles have been broken as tests, and the results of these tests, in which the fracture often takes place outside the weld, have finally led us to consider the welding of thin plates of steel as being as certain and perfect as that of similar pieces of iron. Our experience, therefore, fully confirms that of the English and Scotch builders, whose results have been stated by Mr. Martell and Mr. Kirk at one of the recent meetings of the Institution.[*]

[†] "Treatise on the Use of Steel, in Shipbuilding," by Mr. J. Barba, Second Edition, p. 88.

The communication of Mr. H. H. West, "On Steel for Shipbuilding,"[†] led last year to a very interesting discussion relating to the determinateness of the conditions of resistance and elongation which it would be best to require for the acceptance of steel plates and bars intended for use in the hulls of ships, with a view of deriving all possible advantage from the substitution of this new metal for iron, which had been previously almost exclusively used for work of this kind. Mr. West, and with him the greater part of those who took a share in the discussion, expressed the opinion that it would be necessary with this object to considerably raise the inferior limits required for tensile strain by the Admiralty, by Lloyd's Registry, and even by the Liverpool Underwriters' Registry. Mr. West's opinion is that we ought to fix at 30 tons to the square inch, or at 47.25 kilogrammes per square mm., the inferior limit of tensile strain for accepting iron plates or bars intended for use in shipbuilding, and that we ought at the same time to abandon any superior limit for this tensile strain.

It is worth while to remark, in the first place, that the conditions of tensile strength and elongation which have been adopted in England apply alike to all steel to be used in shipbuilding, whether in the form of rolled plates or bars of any thickness or profile whatever; while the French Navy has, on the contrary, fixed upon requirements of tensile strength and elongation which vary according to the thickness of the plates and bars, or the sectional profile of the bars. The different limits thus specified in the French Navy depend upon experimental results, and should not be regarded as absolutely unchangeable. Already, in fact, some of these limits have been altered, and it is certain that others in the turn would be so, if the necessary for it became evident. It must also be admitted that the limits of tensile strength now imposed still present some singular anomalies, among which we may mention the very great relative difference of 4 kilogrammes per square mm. which there is between the limits of tensile strength required for butt straps in steel plates according to whether these are used along or across grain, and the reduction in tensile strength of 2 kilogrammes per square mm. which is allowed between double T bars and simple T bars and bulb iron (Diagram I, Figs. 1—4, page 408 *ante*) as compared with the lower limit required for bars of all other descriptions. Without attempting to explain these few anomalies, which further experience in the use of steel will doubtless cause to disappear before long, I wish to point out that, excluding boiler iron, for which an exceptional amount of ductility is considered indispensable, the inferior limit of tensile strength required by the French Navy is, as a general rule, higher than that specified by the English Admiralty, by Lloyd's Registry, and even by the Underwriters' Registry. It is only, in fact, for the thicker plates of from 20 mm. to 30 mm., and for the stringers and butt-straps of all thicknesses, worked across grain, that the French Navy allows a lower limit of 44 kilogrammes per square mm. or of 28 lb. to the square inch, which is however, more exactly represented by 44.1 kilogrammes per square mm. This is specified for all through by the Underwriters' Registry for all steel used in the hull. As the thickness of the plates diminishes the inferior limit required in the French Navy increases progressively, and for plates of from 6 mm. to 20 mm. in thickness, which includes nearly all those used in modern constructions, this limit already exceeds by 1 kilogramme per square mm. that of the Liverpool Society.

In order to be accepted for use in the French Navy, thin plates from 1 to 4 mm. thick must be subjected to a minimum test of 47 kilogrammes per square mm., which is nearly equal to the inferior limit of 30 tons to the square inch, or, more exactly, 47.25 kilogrammes per square mm., which Mr. West would wish to see adopted; while the minimum tensile strength of the stringers and butt straps tried along the grain, and that of bars of all sections with the exception of double T bars, T bars, and bulb-iron, should be of still higher tensile strength, namely, 48 kilogrammes in place of 47.25 kilogrammes per square mm. If we remember besides that in the French Navy there is no superior limit to the tensile strength of steel presented for acceptance, it will be seen that the total effect of the conditions required by it has had the effect of furnishing it with steel plates and bars having an actual tensile strength very considerably in excess of those of the similar pieces of steel which are used in the same work in the building yards of Great Britain. We must admit at the same time that this superior tensile strength is not bought in the French Navy at the cost of a reduction of ductility in the steel there employed on account of the requirement of a minimum elongation of 20 per cent. at the moment of breaking; that is to say, an elongation equal to that of the requirement of the British Admiralty and of Lloyd's Registry[*] for all plates of which the thickness exceeds 6 mm. for T bars of more than 4 mm., and for angle irons of from 4 mm. to 6 mm. thickness, while the elongation must exceed 22 per cent. for stringers and butt-straps tested along the grain, and for angle-irons and bulb-irons of more than 6 mm. in thickness. It is only, in fact, for double T irons, T irons, bulb-iron, and so forth, of less than 6 mm. in thickness that is to say, for descriptions in which ductility is evidently of less importance, that the French Navy allows of a final elongation at the moment of fracture less than the 20 per cent. which is required by the Admiralty and by Lloyd's Registry. In short, engineers who think with Mr. West that the tests of tensile strength actually required in England for the acceptance of steel intended for shipbuilding are not severe enough, and that the lower limit of these conditions should be considerably raised, may, as will be seen, find a very conclusive argument in favour of their opinion in the practice of the French Navy. It is for this reason that it appeared to me to be of interest to treat this subject in some detail. The real results of the tests for acceptance, show that the true mean resistance of steel plates from 6 mm. to 20 mm. thick, which are those in ordinary use, cannot be estimated at less than 48 kilogrammes per square mm., and that it therefore exceeds the minimum of 30 tons per square inch, or 47.25 kilogrammes per square mm. proposed by Mr. West; but it is necessary to consider that several tests have only established a resistance equal to or even less than 46 kilogrammes per square mm. without these plates having been rejected. It would therefore appear to us to be imprudent to adopt at once a limit lower than 47 to 48 kilogrammes per square mm. for the acceptance of plates which are now admitted as low as 45 kilogrammes per square mm. In fact, notwithstanding that the Navy assigns no superior limit to tensile strength, such a result is implicitly involved, at least to a certain extent, in the condition of minimum elongation to which it is subject, and the effect of adopting a higher figure for the lower limit of tensile strength would in reality have the effect of making the range of tensile strength between maximum and minimum, within which it would be accepted, far too narrow. The result would unquestionably be that manufacturers, finding themselves thus exposed to the chance of more frequent refusals, would not fail to guard themselves against such an increase of the risk that they run by raising their prices accordingly. Economical considerations of the same character, to which we must add others connected with the necessity for keeping down the delay involved in replacing material which has been rejected, and which consequently affects the rapidity of the execution of orders, decided the French Navy in the adoption, now some years old, of the system of acceptance or refusal at the place of manufacture under the superintendence of engineers specially told off for this service, for all plates and moulded bars, and generally for all forms of steel and iron of any importance, for which requisitions are made on the private trade. This proceeding has not been lightly adopted, a long and minute inquiry having been begun in 1869, and carried on during several years, in the course of which all competent authorities have been called upon to express their opinion upon the advantages and inconveniences which they thought might arise from the application of the tests outside the ports of consignment. The advantages of effecting the tests in the workshops, and settling the acceptance there, have been, moreover, thought so evident and so important, that everybody, almost without exception, thus consulted, has given an opinion favourable to their continuance. The inquiry, therefore, came to an end in 1873, and since that date absolutely nothing has occurred to throw a doubt on the wisdom of the decision taken. It is very certain, on the contrary, that the settlement of acceptance or rejection before the despatch of the iron and steel saves the supply of the materials from a very important part of the accidental risks which manufacturers have some reason to dread, and that by facilitating the business between the manufacturers and the Navy, its result is to lower the price considerably; at the same time—and this last advantage is still more important—the service of the dockyards, of which the requirements are frequently urgent, is thus secured more quickly and more satisfactorily, since it is not exposed to suffer the long delay which rejections of material could not fail to involve if they were only settled after delivery of the material at the arsenal.

[†] Transactions Institution of Naval Architects, vol. xxi., 1880, p. 208

[*] The length of the test pieces is practically much the same on both sides of the channel, 200 mm. in the test for acceptance in the French Navy, 8 in. or 203.2 mm. for the tests of the British Admiralty and Lloyd's Registry. The tests for elongation are therefore perfectly comparable.

(*To be continued.*)

NOTES ON ANCHORS.

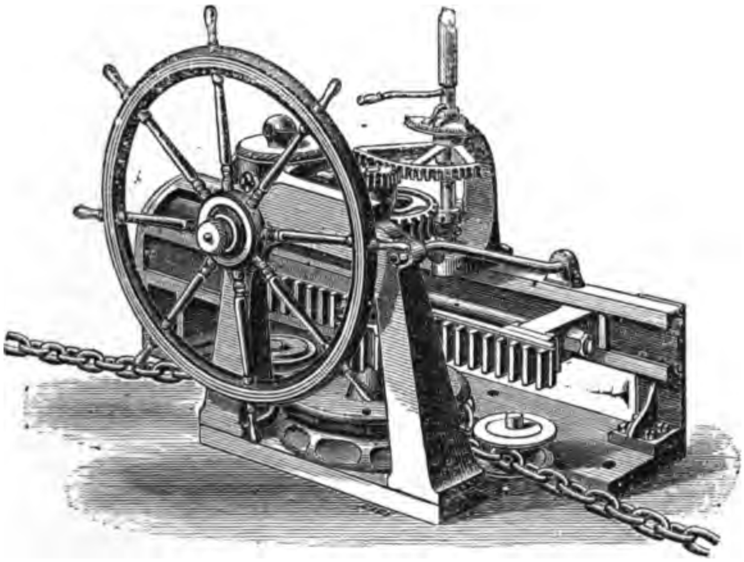
THE possession of thoroughly good ground tackle on board ship, where the valuable lives of so many sailors and passengers are often entirely depending upon its efficiency is of the utmost importance, and yet the construction of the majority of anchors generally in use is such that their *soundness*, owing to the number of welds in each, is a matter of great uncertainty, even when manipulated by the most skilled and careful gangs of anchorsmiths, to say nothing of those made by such workmen whose only aim is to knock out as much work as possible at so much per cwt., not thinking of the serious consequences which may ensue from their endeavours to have a large draw on pay nights. It may be urged that anchorsmiths are deterred from being careless by the knowledge that, if their work does not pass Lloyd's test they are heavily mulcted by deductions from their wages to repair their defective workmanship. This is doubtless true, but is in a manner counterbalanced by the knowledge that a large proportion of their work, especially that for foreign markets, is sent away without being subjected to any proof whatever. It might, however, naturally be supposed that at all events there is safety in the adoption of anchors having a certificate of the Admiralty test from a public proofhouse. No doubt there is *more* safety with such anchors, but still, even in this case, the idea of safety is erroneous, for, although anchors so tested have been subjected to the same *tensile strain* as those used by the Admiralty on board Her Majesty's ships, nevertheless they have not been subjected to the same *proof*, inasmuch as all Admiralty anchors, after being submitted to the regulation tensile strain, are *fire-proofed*, so that any existing defect or flaw (which might not have been observable when the anchor was red hot in the anchorshop before testing), possibly even aggravated by the tensile testing itself, now becomes plainly visible under the valuable safeguard of fire-proofing. It thus follows that all anchors, excepting those for Her Majesty's Navy are subjected to a very *imperfect mode of testing*, and so long as they simply stand the tensile strain and a superficial inspection afterwards, they are put on board ship with whatever internal defects they may have, which do not actually appear on the surface. A further reason why, in the case of anchors, there should be an unusually large margin of strength and certainty of soundness in their construction is that, especially in larger sizes, they are tested to less than one-half the tensile strain of a chain cable of equivalent size, and, moreover, a small portion of each 15 fathoms of chain is cut out and tested to a breaking strain three times as great as that put upon the anchor to which it belongs. The piece of chain subjected to this test is more or less injured thereby, and is consequently thrown on one side, as merely a sample of the average strength of the cable. Such a proceeding could not, of course, be adopted with an anchor without injury by crystallizing the fibres of the iron; nevertheless, the absence of this severe test is the greater reason why anchors should have a larger margin of strength beyond that to which they are actually tested.

SIMEY'S NEW STEAM STEERING MACHINE.

WE are pleased to bring under the notice of our readers an arrangement of steam steering apparatus on the direct acting principle, which has been recently patented by Mr. C. R. Simey, of Sunderland, and of which Messrs. R. Roger & Co., engineers, Stockton-on-Tees, are the sole manufacturers.

The inventor claims for his system and arrangement of steering gear special advantages, which should commend it to the serious attention of shipowners.

It will be seen from our illustration that motion is communicated to the horizontal chain wheel by a rack attached to the piston-rod, and working into a wheel upon the chain barrel shaft in a similar manner to that in which hydraulic cranes are slewed round; and, by a very simple arrangement of valve gear, any one, though uninitiated in steering, can work the machine effectively as regards absence of noise and vibration and also economy of steam. The valve arrangement also is such that the steersman cannot put the helm over too far, while it may, on the other hand, be moved from "hard over" to "hard over" at one stroke of the engine. This feature appears a great advantage over ordinary machines on the "winch" principle, where a considerable number of strokes are required to effect the same result. The slide valve of the engine works on the top of cylinder, which is horizontal, and the steam ports are carried right down to the under side of the cylinder, so that immediately the exhaust ports are opened any water that may be in the cylinder is all carried away by the out-flowing steam in the same manner as in the steam ejector, and so dispensing with the necessity for drain cocks. The machine is so designed that the speed in putting the rudder to "hard over" cannot exceed a certain rate, *whatever the pressure of steam may be*, and the yielding motion of the piston in the cylinder when a sea strikes the rudder is only sufficient to prevent the jar on the machinery. The apparatus is also designed for hand steering, in which case it is worked by means of a worm and worm-wheel, the arrangement generally being such as to prevent the possibility of the steersman being thrown over the wheel, which may be placed as low down to the deck as is found to be convenient. The machine altogether, we understand, requires no more attention, as regards oiling, &c., than an ordinary hand-steering apparatus; the space occupied is also remarkably small, being only 8 ft. athwart ship and 4 ft. 4 in. aft; this, also, for the largest steamers, so that the apparatus can be placed in any ordinary size steering-house, and it is so absolutely silent and free from vibration that it may be placed on the top of a chart-house without annoying the passengers.



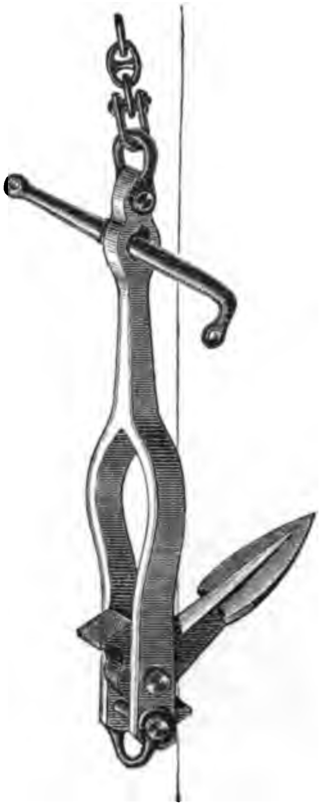
SIMEY'S NEW STEAM STEERING MACHINE.

PATENT ANCHOR.

A NEW kind of anchor, patented by Mr. G. Tyzack, of North Shields (illustrated in this number), has recently, by special resolution passed at a general meeting of the Committee of Lloyd's Register of British and Foreign Shipping, been sanctioned as part of the equipment of vessels intended for classification in the register book of the society. Practical experience of its merits as the working anchor at sea for some years on board several large steamers, besides other severe tests conducted under Lloyd's authority, have decided the Committee to favour this patent with their approval.

The strength of this anchor has been certified by a report under Lloyd's seal, showing that one of them was subjected to various progressive strains, commencing with the ordinary Admiralty test, and increasing until it was broken to destruction with something over three and a half times the Admiralty strain upon it, or 250 per cent. overproof.

This unusual strength is attained by the anchor having only one arm, and the various parts are all increased in strength, to make up the necessary weight required in the classification regulations. The weight of each arm in an ordinary anchor is 25 per cent. of its total, ex stock weight, and this being saved by having only one arm, the parts are proportionately increased in strength. The single arm of this anchor is so arranged that, no matter how it falls or on whatever kind of bottom, it immediately and powerfully holds, in which position it combines the good properties (without the objectionable points) of the Admiralty Rodger, or ordinary anchors, viz.' the strain from the holding part is always in a direct line with the cable, and the vessel can readily swing round at her anchor, the single arm of which acts as a central pivot, and thus has no tendency, as some anchors have, of breaking out of the ground when swinging. There is no projecting arm for a vessel to foul with her cable, and she may in shoal water sit upon this anchor without injuring her bottom. The absence of one arm also makes the anchor less liable to foul vessels' foregrip or to hole her bows when heaving up, and renders it more easy to handle and stow snugly on deck. A further recommendation is that, from its extreme simplicity of construction, being without a weld, it can be soundly made, thoroughly well finished, and put on board at a moderate cost.



An experiment with torpedoes against torpedo nets has just been tried by the Austrian Admiralty at Trieste. A torpedo boat launched a torpedo against a vessel with a torpedo net stationed at a distance of a thousand feet. In twenty-seven seconds the torpedo touched the net and exploded, tearing a hole in the net and sending up a column of water 250 feet in height. The vessel itself was considerably shaken, but not damaged in the least. The charge in the torpedo was half a hundredweight of gun-cotton.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of the* MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Thomas Coats.—On May 27th the Strand Slipway Company launched a steamer of 1,500 tons, built to the highest class at Lloyd's for Messrs. T. Beynon & Co., owners of the Abercarn Colliery, Newport (Mon.). The vessel was named by Miss Swainston, of Sunderland, the *Thomas Coats*, after Mr. Coats, of Paisley, one of the owners, and was admirably launched by Mr. John Crown, managing partner of the Strand Company. She will be fitted with engines of 120-horse power by the North-Eastern Marine Engineering Company, Sunderland, and is designed for the coal and iron ore trades.

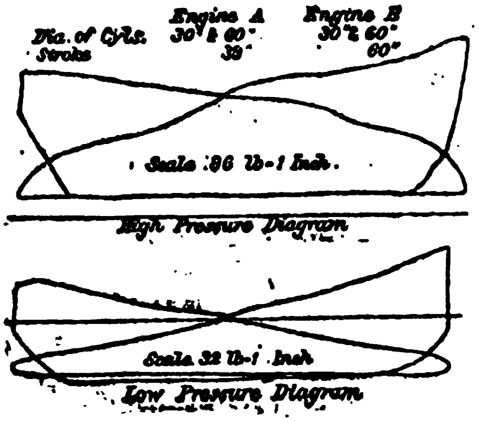
De Bay.—On May 28th, Palmer's Shipbuilding Company (Limited) launched from the Jarrow yard a steamer of 1,700 tons register, called the *De Bay*. This vessel, which is built for Messrs. Capper, Alexander, & Co., of London and Cardiff, is 260 ft. long, 35 ft. 4 in. beam, and 24 ft. 1½ in. depth, and is to be fitted with compound engines working at 80 lbs. pressure, having cylinders 30 in. and 55 in. diameter, with a stroke of 42 in. These will drive a dual propeller on De Bay's patent system. She is fitted with Patent Windlass by Emerson, Walker & Co., London. The vessel is intended for the Eastern and Atlantic trades.

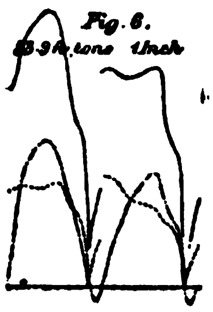
Florence.—On May 28th Messrs. T. Turnbull & Son launched from Whitehall Dockyard, Whitby, a screw steamer of the following dimensions :—Length, 280 ft.; breadth, 38 ft.; depth, 23 ft. 9 in.; with a deadweight capacity of about 3,100 tons, with engines of 180-horse power, by Blair & Co., Stockton-on-Tees, and patent windlass by Emerson, Walker & Co., London. The vessel has been built to the order of Messrs. George Pyman & Co., West Hartlepool, and on leaving the ways was named the *Florence* by Miss Jenny Pyman.

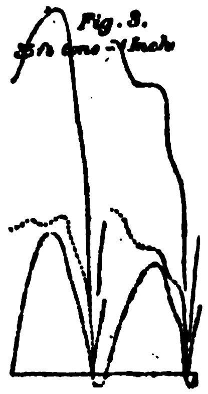
Shelley.—On May 28th Messrs. William Gray & Co. launched from their yard, at West Hartlepool, an iron screw steamer of the following dimensions :—Length, 285 ft. between perpendiculars; breadth, 35 ft. 3 in.; depth, 24 ft. 6 in., class 100 A 1 at Lloyd's. The vessel is built on the three-deck principle to the order of Messrs. Glover Brothers, London, and is intended to carry 2,800 tons deadweight; she is fitted with every recent improvement, including steam-steering gear by Messrs. Halliday, of Sunderland, and patent windlass by Messrs. Emerson & Walker, of London. Her engines are to be fittted by Messrs. Black, Hawthorne & Co., of Gateshead, 180-horse power. On leaving the ways the vessel was named the *Shelley*, by Miss Nichol, of West Hartlepool.

Lemuria.—On May 28th Messrs. Edward Withey & Co. launched from Middleton Shipyard, West Hartlepool, an iron screw-steamer built under the superintendence of Mr. Terrot Glover, jun., to the order of Mr. T. G. Greenwell and partners, of Sunderland. Her principal dimensions are :—Length between perpendiculars, 257 ft. 6 in.; beam, extreme, 34 ft. 6 in.; depth, moulded, 20 ft. 4½ in. She is built to Lloyd's highest class, and has long quarter-deck, bridge-house, and topgallant forecastle, double bottom all fore and aft on the cellular principle, four hatches, and steam winches, and wi'l be topsail schooner rigged. Her decks, chart-house, engine and cabin skylights, and cabin companion are of iron. She will be fitted with engines of 150-horse power, by Messrs. T. Richardson & Sons, of Hartlepool Ironworks. The vessel is No. 98 in the builders' yard, is the third built for the same owner, and the fifth launched by her builders this year. As she left the ways she was christened *Lemuria* by Mrs. J. B. Wilkinson, of Sunderland.

Puerto Riqueno.—On May 28th there was launched from the building yard of Messrs. W. & J. Evans & Co., shipbuilders, Liverpool, a new steamer for Messrs. White, Forman & Co.'s line of Spanish steamers, trading between Liverpool and the island of Porto Rico. Her dimensions are:—280 ft. long, 35·8 extreme breadth, and 24·7 depth of hold, with a gross register of 2,000 tons,







ON STRENGTH OF CRANK SHAFTS.

For description see page 62.

and is built to the highest class on French Lloyd's. She will have engines constructed by Messrs. D. Rollo & Sons, about 250-horse power nominal, on the compound surface-condensing principle, and the vessel and engines were constructed under the superintendence of Mr. G. S. Goodwin. She was christened the *Puerto Riqueno* by Miss Louise Turnbull Forman.

Dorset.—On May 28th Messrs. Joseph L. Thompson & Sons launched from their shipbuilding-yard, North Sands, a screw steamer of the following dimensions, viz.:—Length, 340 ft.; breadth, 39 ft.; depth of hold, 28 ft. 4 in. This vessel has been built to the order of Messrs. Mark Whitwill & Son, of Bristol, for their Great Western line of steamships, trading between Bristol and New York. She is constructed on the longitudinal girder principle, the ballast tanks are divided into eight compartments, six iron bulkheads are fitted, likewise iron longitudinal bulkheads, extending from keelson to upper deck. First-class passenger accommodation will be provided for in the saloon. The 'tween decks of the vessel will be fitted throughout for the transportation of cattle, and the vessel will pass Board of Trade and other surveys necessary for the above requirements. She is of the highest classification at Lloyd's. The engines, which are on the compound surface-condensing principle, are supplied by Mr. George Clark, of the Southwick Engine Works; these are of 300-horse power nominal, indicating 1,500-horse power, having all the modern improvements in marine engineering. She is fitted with Emerson, Walker & Co.'s patent direct steam windlass and other improved machinery. The naming of the vessel, *Dorset*, was performed by Mrs. R. Thompson, of West-house, Fulwell.

Elizabeth Allen.—On May 28 a screw steamer, built for Mr. John Allen, of London, was launched from the iron shipbuilding-yard of Messrs. Bartram, Haswell & Co., South Dock, Sunderland. The principal dimensions of the vessel are:—Length between perpendiculars, 257 ft.; breadth, 35 ft.; depth of hold, 18 ft. 6 in.; deadweight capacity, 2,100 tons. She will obtain the highest class in Lloyd's registry, viz., 100 A1, and M.C. certificate for machinery. The general arrangements of the vessel are—topgallant forecastle, long bridge house, covering engine and boiler spaces, and also the space occupied for the engineers' and officers' cabins, and long raised quarter deck. The cabin in poop aft is fitted up for the accommodation of captain and a few first-class passengers. She is fitted with steam steering gear, by Bow, M'Lachlan & Co.; large size donkey boiler, and four powerful steam winches by Clarke, Chapman & Gurney, and Napier Brothers' patent windlass. The ceremony of christening was performed by Mrs. T. Campbell, wife of the manager of the yard, who named the vessel *Elizabeth Allen*. She will be under the command of Captain Maddix.

Armathwaite.—On May 28th the screw steamer *Armathwaite*, the largest steamer ever built in the Whitehaven Shipbuilding Company's yard, was launched. She is fitted with Emerson, Walker & Co.'s patent brass cone brake windlass, and is a steamer of over 2,200 tons, and belongs to a limited company, Mr. W Burnyeat, jun., being the managing owner.

Peking.—On May 28th Messrs. Wigham Richardson & Co. launched on the Tyne another of the China steamers for Messrs. Siemssen's Line, to the order of Messrs. William Milburn & Co., of Newcastle. The vessel as she left the ways was christened the *Peking* by Mrs. Spence Watson, a sister of one of the builders. The *Peking* is to be fitted with engines of the builders' own make of 200-horse power, from the same design as the engines they made for the Compagnie Transatlantique, calculated for an average speed on service of 10½ knots, and she is now under the 100-ton shears of the Neptune Works, where they are being fitted on board.

Ellangowan.—On June 2nd, the *Ellangowan*, presented to the London Missionary Society by Miss Baxter, of Dundee, was launched from the shipbuilding-yard of Messrs. R. & H. Green, Blackwall, London. She is a composite schooner of 50 tons, yacht measurement, and intended for service at the North of Australia and New Guinea. The dimensions of the vessel are as follows:—Length over all, 60 ft.; beam, 14 ft.; and depth, 7 ft. 10 in. The wood is almost entirely of teak, and in other respects to Lloyd's highest class. The vessel is divided into three compartments, the foremost one for crew, consisting of seven men and the mate; the middle compartment is fitted with broad benches, providing sleeping accommodation for passengers who travel between the different stations doing missionary work, the after compartment being fitted as a saloon, and provided with cabins for the captain on one side, and missionary and wife on the other, each having sleeping berths and all other suitable fittings for the service. This little vessel is to be fitted complete in every respect to enable her to make the voyage out to North Australia. The christening ceremony was performed by Miss Baxter, daughter of the Right Hon. W. E. Baxter, M.P.

Sproston Wood.—On June 2nd, Messrs. R. & H. Green launched at Blackwall a paddle steamer, built to the order of Hugh Sproston, Esq., of the Sproston Dock and Foundry Company, Demerara. Lady Longdon, the wife of His Excellency the Governor of Ceylon, performed the ceremony of christening the vessel, naming her the *Sproston Wood*. The dimensions of the vessel are:—Length over all, 120 ft.; beam (extreme), 29 ft.; depth (moulded), 7 ft. 8 in.; and her load draught with passengers on her station will be about 4 ft.; she has a neat little deck saloon, with a ladies' cabin in the after part. Her machinery will be supplied by Messrs. John Penn & Son, of Greenwich.

Fenella. — On June 9th, there was launched from the building-yard of the Barrow Shipbuilding Company, a twin screw steamer, built to the order of the Isle of Man Steam Packet Company, and intended for their traffic between Glasgow, Liverpool, and Douglas. The ceremony of naming the vessel *Fenella* was performed by Miss Barnett. The *Fenella* is a vessel of about 550 tons, gross register, and her dimensions and particulars are as follows:—Length of keel and forerake, 200 ft.; breadth, 26 ft.; depth, 13 ft. 8 in. Engines, compound d.a., with cylinders 23 in. and 42 in., and two-foot stroke (two pairs), which are expected to give a speed from 13 to 14 knots. The vessel has a long poop, and arrangements are made for a large number of passengers, either for day or night.

Meanatchy.—On June 13th, there was launched from the shipbuilding-yard of Messrs. C. Mitchell & Co., Low Walker, an iron screw-steamer, intended for the Eastern trade. The vessel, which has been built to the order of Messrs. Katz Brothers, of Penang and Singapore, was named the *Meanatchy* by Mrs. Saunders, wife of the future captain of the ship. The steamer is 300 ft. long, 36 ft. beam, and 26 ft. deep, and will be fitted up in the most complete and perfect manner. Her engines, which are 300-horse power, have been manufactured by the Wallsend Slipway and Engineering Company, Limited.

Chateau Leoville.—On June 14th one of the largest steamers built in the port of Sunderland was launched from the yard of the Sunderland Shipbuilding Company. As the steamer left the ways she was christened by Miss Horsley the *Chateau Leoville.* The vessel has been built for a French company. The dimensions are:—Length, 382 ft.; beam, 41 ft.; depth of hold, 31 ft.; gross tonnage, 3,800. She will be engined by the North-Eastern Marine Engineering Company, Sunderland, with engines of 450-horse power. The vessel has three decks, is fitted up for first and second class passengers, and will carry between Bordeaux and New York. She has accommodation for 50 first-class passengers and a number of second-class; will have steering gear of the latest type, and Emerson, Walker & Co.'s patent horizontal direct steam windlass, and be fitted as a three-masted schooner with everything of the best description for all the exigencies of the Atlantic trade. She will also be lighted by Swan's electric light.

Miranda.—On June 14th Messrs. M. Pearse & Co. launched from their iron shipbuilding-yard, at Stockton, an iron screw steamer of the following dimensions:—Length between perpendiculars, 260 ft.; breadth moulded, 33 ft. 6 in.; depth, 23 ft. This vessel, built to the order of Mr. F. Herskind, of West Hartlepool, is about 1,610 tons gross register, and will carry about 2,450 tons deadweight. She is built off the three-decked rule, having two laid, and will obtain the highest class at Lloyd's. She has a short full poop aft, bridge-house amidships, and topgallant forecastle. She will be rigged as a two-masted schooner, having double topsails on her foremast. She will be provided with engines on the direct acting surface-condensing principle, of 150-horse power nominal, from the establishment of Messrs. Blair & Co., of Stockton, is fitted with Emerson & Walker's patent capstan windlass, and has double bottom for water ballast, and all the most recent and improved appliances for expeditiously loading and discharging cargoes. As she left the ways she received the name of *Miranda*, from Miss Herskind, of Seaton Carew.

Largo Bay.—On June 14th there was launched from the shipbuilding-yard of Messrs. Andrew Leslie & Co., of Hebburn-on-Tyne, a steamer, built to the order of Messrs. Affleck & Gray, of North Shields, and intended for the Indian, American, and Black Sea trades. The dimensions of the vessel are as follows:—Length, 260 ft. between perpendiculars; breadth, 34½ ft.; depth, 23½ ft. The vessel has a full poop, long bridge, and topgallant forecastle; has been built under special survey, and is classed 100 A1 at Lloyd's. She has a carrying capacity of 2,500 tons. As the vessel left the ways she was named the *Largo Bay* by Miss Kate Andrews, the daughter of Mr. Joseph Andrews, North Shields. The steamer will proceed to Sunderland to receive her engines, which are of 180-horse power nominal, and built by the North-Eastern Engineering Company.

Cubano.—On June 14th there was launched from the shipbuilding-yard of Messrs. Robert Thompson & Sons, Southwick, an iron screw steamer, built to the order of Senor M. M. de Arrotegui, of Bilbao, of the following dimensions, viz.:—Length, 332 ft.; breadth, 32 ft.; depth, 25½ ft. She has been constructed under Lloyd's special survey to class 100 A 1. Her engines, which are of 300-horse power, are by Mr. Geo. Clark, Southwick. The vessel has two iron decks, the upper one being covered with wood, full poop, bridge, and topgallant forecastle; also an iron wheel and chart-house on the bridge. She has been fitted with all the latest improvements, including six bulkheads, all necessary water ballast and large freshwater tanks, with condenser. The cabin is fitted up aft with captain's and spare berths, the bridge-house amidships, with galley and accommodation for officers and engineers, and for seamen and firemen in forecastle. She has four steam winches and large donkey boiler by Messrs. E. Roger & Co., Stockton, patent midships, steering apparatus by Messrs. J. H. Wilson & Co., Liverpool, patent screw gear aft, Harfield's patent windlass, &c. As the vessel left the ways she was christened the *Cubano* by Miss Soberon, of Liverpool.

Muriel.—On June 15th there was launched from the yard of the Tyne Iron Shipbuilding Company (Limited), at Willington Quay, on the Tyne, an iron screw steamer, built to the order of William Buchan Ritchie, Esq., of Dundee, of the following dimensions, viz.:—Length, 300 ft.; breadth, 36 ft.; depth, moulded, 26 ft. This vessel is to be fitted especially for the Atlantic cattle trade, and for general trades, and will have engines of 38 in. and 71 in. by 45 in. stroke, from the North-Eastern Marine Engineering Company (Limited), of Sunderland, and patent direct steam windlass by Emerson, Walker & Co., London. She was named *Muriel* by Miss Ritchie, daughter of the owner, and will be commanded by Captain Alexander Laws.

Toledo.—On June 18th Earle's Company launched from their yard, at Hull, a steel steamship for Messrs. T. Wilson, Sons & Co. As she left the ways Miss Violet Dobree christened her the *Toledo.* She is built of Martin-Siemen's steel, and is 260 ft. long, 34 ft. broad, and 18 ft. deep. Her gross tonnage is estimated at 1,700 tons, and it is calculated that she will carry 2,200 tons deadweight. She will be brigantine rigged, and has a long quarter deck and bridge. She will have all the most modern improvements for discharging and loading cargoes at four hatchways. The *Toledo* is a similar but larger vessel to the *Borodino*, *Gitano*, and *Sirio*, recently built by Earle's for Messrs. Wilson, and she is intended for the Baltic and general trade. The vessel will be propelled by a single crank engine, of 120-horse power, which will work up to 700 nominal.

Glenmavis.—There was launched from the Jarrow-yard of Messrs. Palmer's Shipbuilding and Iron Company (Limited), an iron screw steamer, built to the order of Messrs. Lindsay, Gracie & Co., Newcastle-on-Tyne, and named the *Glenmavis* by Mrs. Lindsay, wife of one of the owners. The *Glenmavis* will carry 3,300 tons on an easy draught, and is fitted with powerful engines and large boilers. This is the fourth boat built by Messrs. Palmers for the above-named firm.

LAUNCHES.—Scotch.

Fieramosca.—On May 28th, the *Fieramosca*, of Castellamare, an iron screw-steamer, 133 ft. long, was launched at Paisley by the Abercorn Shipbuilding Company, who will fit her with powerful engines for a guaranteed speed of 13 knots. She is classed at Lloyd's, and will have a Board of Trade certificate for passengers, being intended to ply in the Bay of Naples with passengers. The owners are Italian, and contracted for her through Messrs. M'Nicoll and Smith, Glasgow, who are superintending her construction.

Ella.—On May 28th, Messrs. Aitken & Mansel launched from their yard at Whiteinch a screw steam vessel of 750 tons register, built to the order of the London and South-Western Railway Company. This vessel, which was named the *Ella*, will be fitted with compound engines of 220-horse power nominal by Messrs. John & James Thompson, Finnieston, and is now the seventh vessel which Messrs. Aitken and Mansel have supplied to the London and South-Western Railway Company for their passenger and cargo service from Southampton to the Channel Islands and French ports.

Bessie.—On May 28th, Messrs. Thomas B. Seath & Co. launched from their Shipbuilding-yard, at Rutherglen, an iron steam yacht for Mr. John Clark, of Paisley. The vessel, which is named *Bessie*, is of the following dimensions:—Length, 67 ft.; breadth, 12 ft.; depth, 8 ft. 3 in.; and 42 tons yacht measurement. She is fitted with compound surface-condensing engines of 28 nominal horse-power, has 80 lbs. working pressure of steam, and will attain a speed of 10 knots an hour. The engines are supplied by Messrs. Thomas Reid & Son, Paisley.

White Sea.—On May 28th, the second of two steamers which have just been built for the Dundee, Perth and London Shipping Company, was successfully launched from the shipbuilding-yard of Messrs. Alex. Stephen & Sons, Dundee. The new vessel is a sister ship to the *North Sea*, launched for the same Company about six weeks ago, and in every respect duplicates her arrangements. She is 1117 tons gross, and her dimensions are—length. 230 ft.; breadth, 30½ ft.; and depth in the hold, 17 ft. 2 in. Like the *North Sea*, she has been built by Lloyd's rules to class A1 at Lloyd's, and everything has been done to secure large cargo-carrying capacity, combined with small working cost and a fair rate of speed. She will be fitted with engines of 120-horse power, made by Messrs. Pearce Brothers, Lilybank Foundry, and will have steam-steering gear on an improved system supplied by Mr. W. B. Thompson, and Emerson Walker & Co.'s Patent Combination Windlass. A large number of persons assembled to witness the launch, and as the vessel left the ways, a few minutes before three o'clock, she was christened the *White Sea* by Miss Lizzie Leng. The *White Sea* was immediately towed round to the large steam crane in Victoria Dock, where her engines and boilers will be put on board.

Godolphin.—On May 28th there was launched from the shipbuilding-yard of Messrs. W. Pickersgill & Sons, Southwick, a screw steamer of the following dimensions:—235 by 33 by 16, and built to the highest class in Lloyd's to the order of Messrs. J. P. Ninnes & Sons, for the *Godolphin* Steamship Company, of Cardiff. She is well adapted for the shallow Black Sea ports, and the Bilbao trade, and will be fitted with three steam winches, Emerson & Walker's patent windlass, screw steering apparatus, and all the latest improvements. As the vessel left the ways the ceremony of christening was performed by Mrs. H. W. Williams wife of H. W. Williams. Esq., Assistant General Manager of the London & St. Katharine Docks, London, one of the shareholders of the company.

Locust.—On May 30th Messrs. Blackwood & Gordon launched from their shipbuilding-yard at Port Glasgow an iron steamer named the *Locust*, built to the order of Mr. John Burns for the Belfast trade with Greenock. The following are her dimensions:—190.6 by 25 by 13, and about 560 tons. She will be furnished by her builders with compound engines of 100-horse power. This is the second of three steamers for the same trade and owner by Messrs. Blackwood & Gordon for the cattle trade.

Abana.—On May 30th Messrs. Chas Connel & Co., launched from their shipbuilding yard at Scotstoun an iron screw steamer of 2,500 tons. She is classed 100 A 1 at Lloyd's, and has been built to the order of James M. Wood, Esq., Shipowner, Liverpool, and is fitted up with every facility for the rapid loading and discharging of cargo. As she left the ways she was named the *Abana* by Mrs. Newall, Leith, and was immediately towed to the harbour to get her machinery fitted on board, which is being supplied by Messrs. John & James Thomson, Finnieston Engine Works.

Largo Law.—On May 31st Messrs. Napier, Shanks & Bell launched from their Yoker shipyard an iron sailing ship of about 1,720 tons, built to the order of Mr. David Law, Glasgow, and having Lloyd's highest class, under special survey. The *Largo Law*, as the new vessel is named, is fitted with the most complete and approved appliances for her intended service. The ceremony of naming was performed by Mrs. Law, and in a few weeks the *Largo Law* will proceed to San Franciso under Captain Niven. After being successfully canted in the river, the vessel was towed up to Finnieston Quay to get her equipments completed.

Berwick Law.—On June 2nd Mr. Robert Chambers, jun., launched from his building yard, Lower Woodyard, Dumbarton, a barque of about 1,700 tons burthen. The vessel is built to the order of David Law, Esq., of Glasgow, and will load for Calcutta. As she left the ways she was named the *Berwick Law*, by Miss Jessie Law, grand-daughter of the owner.

Cavour.—On June 2nd Messrs. Scott & Co., Shipbuilders, Greenock, launched from their shipbuilding-yard a screw steamer of the following dimensions:—Length, 208 ft.; breadth, 32 ft.; depth, 12 ft.; and 650 tons gross measurement. She will be supplied with compound surface-condensing engines of 100-horse power nominal—the cylinders being 23 and 50 inches respectively. The steamer has been built to the order of Messrs. Lamport & Holt, Liverpool, and is intended for the Brazilian coasting trade. As the vessel left the ways she was named the *Cavour*.

Pallas.—On June 7th Messrs. Alexander Stephen & Sons launched from their yard at Linthouse, Govan, an iron screw steamer of the following dimensions:—192 by 26 by 14, and classed 100 A1, with compound surface condensing engines, having cylinders 26 in. and 47 in. diameter by 30 in. stroke. The vessel was named the *Pallas*, by Miss Grace Horne, Port Glasgow. The *Pallas* has been built to the order of Messrs. Jex & Co., New York, and is specially designed and fitted up for the fruit and passenger trade between New York, Honduras, and other Central American ports.

Galatz.—On June 9th, Messrs. A M'Millan & Sons, launched, at Dumbarton, the French mail steamer *Galatz*, 1,600 tons register and 1,400-horse power. The *Galatz* will form one of the fleet of Messrs. Fraissinet & Co., of Marseilles, and is intended for service in the Mediterranean. She is the first of four steamships building by Messrs. M'Millan for the same owners. The *Galatz* was named by Monsieur F. Rolland, Marine Superintendent of Messrs. Fraissinet's fleet.

Pieter de Coninck.—On June 11th, Messrs. Alex. Stephen & Sons launched, at Linthouse, an iron screw steamer of about 3,500 tons, built to class 100 A 1, with awning deck, and fitted, before launching, with engines having cylinders 44 in. and 80 in. diameter, by 48 in. stroke. This steamer is for Messrs. Theodore C. Engels & Co., of Antwerp, and is intended for the trade between Antwerp and New York. She is specially adapted for the trade, and has accommodation for a few first-class passengers, and arrangements for a large number of emigrants, besides the most approved appliances for working cargo, carrying cattle, &c., and is also fitted with Emerson, Walker & Co.'s patent direct-acting steam windlass with their patent self-acting compound frictional brakes fitted, steam steering gear, provision for water ballast, &c. The vessel was named the *Pieter de Coninck* by Mrs. Dunn, wife of the Belgian Consul.

Abeille IX.—On June 13th, Messrs. Cunliffe & Dunlop launched from Inch Work, Port Glasgow, a twin screw tug steamer, built to the order of Messrs. A Wolter & Co, Havre, as an addition to the fleet of the Compagnie des Abeilles of that port. Her dimensions are as follow.—Length, 125 ft.; breadth, 19 ft.; and depth, 13½ ft. The engines of the new steamer will be capable of exerting 300-horse power each, or 600-horse power collectively, and will be able to propel the vessel at a high rate of speed. In addition to high engine power and speed, the vessel is fitted out forward, for the conveyance of passengers, with a large saloon. The towing arrangements provide not only for the towing of large vessels at sea, but for taking six to eight vessels up the river from Havre to Rouen. The ceremony of naming the vessel *Abeille IX.* was performed by Miss Sommerville, of The Manse, Irvine.

Gelert.—On June 14th Messrs. John Fullerton & Co., shipbuilders, Merksworth, Paisley, launched an iron screw yacht, of 120 tons, built to the highest class at Lloyd's, and to the order of Albert Wood, Esq., Bodlondel, Conway. Her engines, of 35-horse power nominal, have been fitted on board by Messrs. De Winton & Co., of Caernarvon. The whole of the deck fittings are of teak, she has a spacious deckhouse with promenade on top, and cabin under deck. Accommodation is provided for Officers and Crew in cabins abaft of engine-room. She is supplied with steam windlass, screw steering-gear, Chadburn's patent telegraph, and all the latest improvements. On leaving the ways the yacht was named *Gelert* by Miss Fullerton, Merksworth.

On June 17th, a new iron hopper dredger of 1,800 tons, built and engined by Messrs. W. Simons & Co., was launched from their works at Renfrew. It is the property of the Otago Harbour Commissioners, and will dredge from 3ft. to 35ft. depth, and carry 1,400 tons of its own dredgings. It is fitted with twin screws, two sets of compound engines, collectively of 700 indicated horse power, centrifugal pumps, and steam appliances for mooring, lifting, dredging and manœuvring. This vessel is over 200 feet in length, and is the tenth and largest hopper dredger this firm has constructed.

Allemannia.—On May 26th, Messrs. Dobie & Co., launched from the Govan shipbuilding yard another iron screw steamer, built by them to the order of the Hamburg-American Company, to the highest class, and measuring 1,900 tons. The steamer is the third one of the same type supplied to the company by the builders. As she left the ways she was named the *Allemannia* by Miss Alexander, acting for Mrs. Leitke, the wife of the Consul for the German Empire.

Cormorant.—On May 26th, Messrs. Barclay, Curle, & Co. launched at Whiteinch an iron screw steamer of 2,300 tons register for the Bird Line of Messrs. Seater, White, & Co., Leith. As the steamer left the ways she was named the *Cormorant* by Mrs. George S. Seater.

TRIAL TRIPS.

Taldora.—On May 27th, this screw steamer had a run over the measured mile at Wemyss Bay, when the guaranteed speed of 10 knots was obtained. The *Taldora* has been built by the Campbeltown Shipbuilding Company to the order of Messrs. M'Ilwraith, M'Eacharn & Co., of London, and is expected to sail in a few days for Rockhampton, Australia, where she will take up her station. The vessel is adapted for river traffic there, having a semi-awning deck fitted, also arrangements made for towing and for passengers.

Juliet.—On May 28th, the *Juliet* (s), built by Messrs. Raylton Dixon & Co., for Messrs. C. T. Bowring & Co., of Liverpool, for the Red Cross Line of steamers from the Tyne to New York, left the Builders'-yard to make her trial trip. This vessel, which has been constructed of extra strength for the Atlantic trade, is 285 ft. over all, 36 ft. beam, and depth of hold to floors is 24·6. She has water ballast in her after hold, and in a large chamber tank, which can be also used for cargo. She is built on three deck rule, two being laid, and has a long bridge amidships, under which is a saloon, and accommodation for her officers and engineers. Being intended for the cattle trade, she has been specially arranged for the protection of cattle by a long shelter deck as a continuation of the forecastle, and also has iron beams over the upper deck aft, to which temporary shelter boards can be fixed to protect cattle on this part of the ship. She has also a hood aft for the protection of the steering gear, and under this are cabins for the cattle-keepers. In the 'tween deck forward is accommodation for fifty emigrants, and the crew are lodged under the forecastle. Her outfit contains all the latest improvements, such as iron lighthouses on the forecastle, Higginson's steam "quarter-master," and all Board of Trade passenger requirements, also Sir W. Thomson's patent compasses. She is fitted with engines of 200-horse power by Messrs. Thomas Richardson & Sons, of Hartlepool. At high tide she proceeded down the river, made a run in the bay, and thence left for Dundee, where she will call on her way to New York. A large number of emigrants for America left Middlesbrough with her.

Stormcock.—On May 30th, the new iron-screw steamtug *Stormcock*, built by Messrs. R. and H. Green, Shipbuilders, Blackwall, London, to the order of Messrs. Holland, Doust & Co., Gravesend, left the Brunswick Pier, Blackwall, to run on her trial at the measured mile, Long Reach. This vessel is one of the largest screw tugs ever built for plying on the River Thames. Her dimensions are as follow:—Length between perpendiculars, 80 ft.; beam, moulded, 16 ft.; depth in hold, 9 ft. 3 in. She has a bridge-house amidships, and is fitted with all the latest improvements as to coal carrying, steam windlass, organ whistle, patent steering gear, slip towing hooks, signal lamps, &c. She has powerful machinery supplied by Messrs. Alexander Wilson & Co., Vauxhall Iron Works, and will be capable of towing vessels of 1,000 tons in a tideway, her engines being able to work up to 250 indicated horse power. The following result was obtained on her trial, viz.:—A mean speed of 10·74 knots with 70 lbs. of steam; all the weights being on board, it was considered very satisfactory, and beyond the estimated speed of the designers. The machinery during the trial worked with perfect smoothness, and the trial in all respects gave the greatest satisfaction to the owners.

Carmona.—Two steam-tugs, the *Iron King* and the *Renown*, were on May 31st required to convey on board the fine steamship *Carmona*, lying in the Roads, the guests invited by Mr. William Thomson and the other owners to enjoy the trial trip. For a trial trip the weather was everything that landsmen could desire. While the heat on shore was stifling and oppressive, there was a delicious southerly breeze on the river and out at sea which braced the spirits, whetted the appetite, and put every one on good terms with himself and everybody. The party of ladies and gentlemen was perhaps the largest that ever sailed from the Tay on such an occasion, the number being estimated at from 300 to 400. Crowded on the decks of the tugs they looked a formidable company, but spread over the spacious deck accommodation of the *Carmona* there was ample room and verge enough for all to move freely about and admire the beauty of the scenery and to inhale the invigorating ozone. By a quarter-past eleven o'clock all was in readiness on board, and the *Carmona*, under the command for the day of Captain Lee, and gay with bunting from stem to stern, steamed slowly until opposite Broughty Ferry, when the speed was increased. Passing the Lightship the crew gave the usual salute, which was promptly acknowledged, and the *Carmona*, settling down as if to show what she could do, sped quickly to the Bouy of Tay, from which point to the Bell Rock, the distance of a little over nine knots was covered in about forty minutes, being at the rate of 13 knots an hour. The ensign having been dipped in response to the signals made from the Bell Rock keepers, the *Carmona's* head was turned northwards, and, approaching close to the shore near Auchmithie, the steamer sailed as far as Lunan Bay, those on board being afforded a splendid opportunity of viewing the grandeur of the line of rock-bound coast. When the lighthouse at Scurdyness at the mouth of the Southesk was in view on the larboard bow, the *Carmona* was again put about, and, making once more for the Bell Rock, a most enjoyable sail was continued till Dundee Harbour was reached between five and six o'clock. On the run back the speed of the steamer from the Bell Rock to the Bouy of Tay was maintained at the rate of 14½ knots—a result highly creditable to the builders. The *Carmona*, it may be here of interest to repeat, is the largest steamer ever constructed in Dundee. Her dimensions are—Length between perpendiculars, 350 ft.; breadth moulded, 42 ft. 6 in; depth moulded to awning deck, 35 ft. 2 in.; tons gross, 3714 46-100; tons nett register, 2447 25-100. She was built by Messrs. Gourlay Brothers & Co., and is specially designed and fitted for the American cattle trade. Her engines of 380 horse-power nominal were under the superintendence of Mr. M'Farlane. With 80 lbs. of pressure they made 62 revolutions per minute, and the trial gave the utmost satisfaction to all the nautical authorities on board, as well, it may be added, as to those whose seafaring knowledge could barely distinguish the topmast from the keelson. She carries a powerful steam capstan windlass, Emerson Walker & Co.'s Patent, London. During the run up the river luncheon was served to all the guests, and it goes without saying that on such a day the most ample justice was done to the supplies, which were of good quality, and were served in abundance. The unanimous opinion was that the trial trip of the *Carmona*, thanks to the forethought and attention of the owners, from Mr. Thomson downwards, was one of the happiest and pleasantest ever enjoyed on the Tay. The *Carmona*, under the command of Captain Halcrow, sailed the next morning for Shields to load.

Clytha.—On June 2nd, this steamer, built by the Tyne Iron Shipbuilding Company, Willington Quay, for Messrs. Stephens, Mawson, & Co., of Newport (Mon.), had her trial trip from Shields. A speed of 10¾ knots was obtained. She is 220 ft. long, 39ft. broad, 15 ft. deep, and will carry 1,250 tons deadweight.

Dryburgh Abbey.—On June 8th, the screw-steamer Dryburgh Abbey, belonging to Messrs. Wood, Brothers & Co., of Liverpool, made a trial trip to sea. The wind was blowing a gale and a very high sea was running, yet the steadiness of the vessel and the smooth working of the machinery were subjects of general remark. After a satisfactory run of several hours, the steamer returned to the harbour to complete her loading for Madras. The *Dryburgh Abbey*, of the Abbey Line, was built and engined by Messrs. Wigham Richardson & Co., of the Neptune Works. She has Emerson, Walker & Co.'s patent windlass, and has been arranged in every detail of hull and machinery to suit both the American & Eastern trades.

Pelham.—The trial trip of this new steamer, of 450 tons burthen, built by Messrs. Hodgson & Soulsby, of Blyth, engined by Messrs. Smith Brothers, of Glasgow, and recently sold to Messrs. Goddard, Collingwood & Morton, of Grimsby, trading under the firm of Grimsby & London Trading Company (Limited), took place on June 21st. The steamer left Blyth for the measured mile, where the speed was proved to be 11 knots an hour. The trial gave great satisfaction to all interested. The boat steamed back to Blyth to load.

Cameta.—This paddle-wheel steamer, constructed by Messrs. Laird Brothers to the order of the Amazon Steam Navigation Company, and intended to be employed in the conveyance of mails, passengers, and cargo on the Amazon, has made her official trial trip with very satisfactory results, obtaining a mean speed on the measured mile of 12½ knots, the engines working smoothly and developing about 700-i.h.p. Like the two sister vessels, *Maud* and *Ica*, recently despatched to Brazil, the *Cameta* is 180 ft. long, 28 ft. broad, and 9 ft. 6 in. deep in hold, measuring 648 tons O.M. She carries 230 tons deadweight on a load draught of 6ft. 6in., and is fitted with direct-acting diagonal engines on the compound system, working at 75lbs pressure. The hull is arranged with special regard to service in the tropics, and has a complete spar deck, and above that a wooden awning deck or sunshade. The machinery, coal and cargo are below the main deck, which is left open, and on the spar deck are the cabins for passengers, Officers and Crew. A trial was made to ascertain the consumption of fuel, and the result showed a rate of about 9¼ tons per 24 hours, with engines working to 500-horse power, or a little under 2 lbs per i.h.p. per hour. The *Cameta* is the 13th steamer built by Messrs. Laird for the Amazon Steam Navigation Company and its predecessors, for the navigation of that river.

Notting Hill.—The large steel twin-screw steamer *Notting Hull*, whose novel arrangements have been exciting considerable interest in the Clyde and Mersey, was on June 10th inspected at the Tail-of-the-Bank previous to proceeding to Liverpool, where she completes her loading for Calcutta, her maiden voyage being under the auspices of the well-known City Line. The *Notting Hill* differs in many respects from the usual style of large ocean-going passenger steamers. Her great power, 3,200-horse power indicated, is exerted through two screw propellers. Nothing of such magnitude has hitherto been attempted outside of Her Majesty's navy, where all the largest and fastest fighting ships of recent construction have been fitted as twin screws, owing to the handiness and safety thus secured. The steamer herself, with her large oval bell-mouthed funnel, her long house on deck, her four masts at regular intervals, her side hatches and forest of derricks, presents a remarkable appearance. She is 420 ft. long by 45 ft. beam, so that in these dimensions she is exceeded by very few steamers afloat. Her depth is 26½ ft.; gross tonnage 4,021; registering net 2,616. She was built by Messrs. Dobie & Co., of steel, to Lloyd's highest class for hull and machinery. The Admiralty have enrolled her in their transport service list, and her watertight bulkheads—all extending to the upper deck—were calculated by the Construction departpartment as sufficient to float her with any one compartment open to the sea. The engines are constructed by Messrs. Jas. Howden & Co., Glasgow, and each pair consists of two compound inverted vertical direct-acting surface-condensing engines, 32½ in. diameter in high pressed cylinder, and 76 in. in low, with 4 ft. stroke. They are supplied with steam of 125 lbs. pressure from ten of Turner's patent boilers. The whole of the boilers and pipes have been pressed to 250 lbs. The coolness of the stokehole, notwithstanding the number of boilers and the pressure, is a remarkable feature of the arrangement. Her crank-shafts and propellers are of Vickers's cast steel. She is fitted with a powerful horizontal direct steam capstan windlass, Emerson, Walker & Co.'s patent. The *Notting Hill's* cabins, in a large house on deck amidships, are fitted up in a quaint old English fashion, which has a tasteful and home-like effect. The state-rooms, so often sacrificed in order to add to the display of the grand saloon, are so large in the *Notting Hill* that it has been found practicable to give each occupant a comfortable berth open to the ceiling. There are no upper berths. Every room has an unusually large window, which, being in a house on deck instead of in the ship's side, can be opened in almost any state of the weather. The bath-rooms and other conveniences are in unusual number, and excellently arranged. There is a handsome ladies' saloon at the fore end of the house, and a library of the newest works completes the attractions of the steamer for passengers.

Notes and Novelties.

THE "CONQUEROR."—Another powerful armour-clad ship, the *Conqueror*, will be launched from Chatham Dock-yard in the course of the ensuing month.

A NEW life-saving buoy is now being issued to her Majesty's Navy, which presents, it is stated, many advantages over those hitherto in use. By the employment of phosphate of calcium, upon contact with the water, a bright flame at once springs up, clearly marking the position of the buoy, both to those on board the ship and to the person overboard. This property of combustion upon contact with water has, however, one disadvantage, as it will necessitate great care in stowage, to prevent the possibility of a fire, thereby arising.

A STEAMSHIP REGISTER.—We have received from Messrs. Pile & Co., shipbuilders, &c., of Great St. Helens, a copy of their register of steamers for sale. This is a thick pamphlet, very full of useful information, and entirely unlike anything of the kind ever published before, in that it is very fully illustrated by lithographs, the drawings being for the most part longitudinal sections of ships. Many of these are folding plates. They save a great deal of description, and give an intending purchaser an accurate idea at once of what Messrs. Pile have to sell. The register is likely to prove specially interesting to yachtsmen, as it contains many illustrations of steam pleasure craft, and the drawings of these show their internal arrangement very clearly. The whole pamphlet is exceedingly creditable to Messrs. Pile.

THE NEW DOCKS, LEITH.—Last week, in presence of the members of the Leith Dock Commission, water was introduced from the sea into the new dock which has just been completed at Leith. The works, which were commenced in October, 1874, include a wet dock, a graving dock, breakwater, sheds, &c.; and the total cost will amount to about £400,000. The extent of the wet dock is about 16 2-3 acres, and the graving dock is 300 feet long, exclusive of the entrance, and 48 feet wide. It is expected that the dock will be formally opened in August next. The names "Gladstone Dock" and "Edinburgh Dock" have been suggested for the new works.

PROPOSED NEW DOCKS ON THE THAMES.—All opposition to the Bill which recently passed the House of Lords, authorizing the construction of a dock and quay walls on the River Thames, having now been withdrawn, the Bill will pass through the House of Commons unopposed. The proposed new dock will be situated at Dagenham, in Essex, some three and a half miles further down the river than the present Victoria and Albert docks, and immediately on the line of the London, Tilbury, and Southend Railway. The water space of the dock will be 75 acres in extent, with a depth of 35 feet below high water of ordinary spring tides. The quayage enclosing the above water will be upwards of two and a half miles in length, and the dimensions generally wil be sufficient to allow of the largest vessels afloat entering and turning in the dock. For the construction of it the Bill gives powers to incorporate a Company with a share capital of £1,500,000 with borrowing powers to the extent of £500,000.

A FLOATING CRANE.—There was launched on June 11th, from the yard of Messrs. Samuda Brothers an interesting novelty in mechanical appliances. This consists of a twin-screw steam vessel, travelling at five miles an hour, and carrying a steam crane capable of lifting 30 tons to a height of 60 ft. above the water and of traversing a complete circle of 47 ft. radius. The vessel is 100 ft. long and 44 ft. broad; the crane is 70 ft. high; the vessel, crane, and counter-balance are worked by steam machinery driven by separate engines, so arranged as to be under the control of one man. Provision is thus made for lifting or transporting any weight up to 30 tons from the quay or from craft into a ship's hold, or *vice versa*, in much less time than is necessarily occupied by a derrick, for masting or dismasting vessels, and for fitting out or repairing the largest ocean-going steamers. The crane and machinery have been entirely designed and constructed by Messrs. Hunter & English, of Bow, for the London and St. Katherine Docks Company's use in their Royal Albert and Victoria Docks, where the vessel can be seen at work in ten days' or a fortnight's time.

AMONG the most noticeable novelties in ship-building, we observe some vessels building in Messrs. Halsey & Co.'s Yard, Wandsworth. One large model, measuring eleven tons, and attaining a speed of eight miles per hour, with twenty people on board, the draft being only four inches. The model is to illustrate a proposed vessel for Channel service. Another vessel commenced will measure 592 tons, and is to be 45 ft. beam, the largest craft ever built above London Bridge. This craft is to be propelled by engines on the Perkins' system, to work up to 800 h.p. An entirely new form of submerged torpedo, driven by a Six-Cylinder Halsey Engine, which is capable of being steered at will, and will attain a speed of fourteen knots; the motive power, "some chemical," is the subject of a patent. The same firm has just contracted for fifteen steam launches, 120 ft. long by 20 ft. beam, with a guarded feathered propellor, for deep sea fishing in the North Sea. Also two very handsome yachts of about sixty tons, of galvanized steel, for the Mediterranean, suitable for transit *vià* the French canals. The steel has undergone immersion in a bath prepared by this firm, which enables it to maintain its malleable and ductile qualities after the galvanizing process. They have besides a large number of their smaller gigs building, one of them to work with petroleum fuel.

Recent Applications for Patents connected with Marine Engineering, Ship Construction, and Mechanical Appliances for use in Ships, from 20th May to 20th June, 1881.

EDITORIAL NOTES.

WE have, it seems, by no means learnt all that propellers can teach us. The tests of the torpedo boat *Lightning* have given very marked results in favour of the new form of propeller fitted thereto. The alteration there tested is not in the form of the screw itself, but in the direction and control of the stream of water issuing from or delivered by the screw. It is well known that many of the improvements that have been sought to be effected in propellers have had for their object the better direction of the stream of water from the screw and the avoidance of churning; but the apparatus to which we refer, as fitted to the *Lightning*, serves to control the issuing stream of water by a cylinder—that is, a screw of small diameter is enclosed in a cylindrical casing, and is thus obliged to deliver an unbroken column of water in the direct axis of the vessel. So far, the apparatus is similar to that of Mr. Rigg and Mr. Parsons; but this apparatus, which is the invention of Mr. Thornycroft, has the especial feature of a long central cone, extending far to the rear of the enclosing cylinder. Fixed guide plates are also attached to the rear of the enveloping cylinder which are operated by the rudder, so that when amidships the water is delivered directly aft, but when put hard over the opposite wing closes, and the stream of water is driven towards the rudder side. This makes the vessel answer to its helm with very great readiness, so that the vessel can circle to port in 1 min. 15 sec., and to starboard in 1 min. 5 sec. As her speed, also, is over 19 knots, which is effected by a screw of 3 feet in diameter, as compared with a screw which was formerly 5 feet 6 inches in diameter, the improvement effected by the invention is a very substantial one.

So MUCH public attention has been directed of late to the tunnel under the English Channel that an almost similar, though smaller, undertaking at Liverpool has been almost lost sight of. Many years ago the project of a Mersey tunnel to unite Liverpool and Birkenhead directly was set on foot, and a pioneer company was founded for the purpose. The funds subscribed by this Company were, however, soon exhausted in preliminary borings and investigations, so that the disheartened shareholders were glad to dispose of their rights to a private firm. Messrs. Brunlees & Fox since then have been energetically carrying on the preliminary work and borings in a quiet and cautious manner. They have, however, proved by a preliminary shaft and borings that the whole course of the proposed tunnel will lie through new red sandstone of a hard and compact character. They have as preliminary work sunk two large shafts, one at each end, to a depth of 180 feet, and have driven a horizontal drift some 200 yards from the Birkenhead side, and half that distance on the Liverpool side. As the whole distance to be tunnelled is only 1,600 yards, one-fifth of the most essential part of the undertaking has already been accomplished. Messrs. Brunlees & Fox now consider themselves in a position definitely to state that no engineering difficulties need be anticipated in the tunnel beyond the usual leakage through fissures in the red sandstone bed. The minimum thickness overhead will nowhere be less than 25 feet. The leakage to be expected can be easily dealt with by the powerful pumping engines already laid down at either end. The estimated cost of the whole undertaking is only £866,000, and the work could be completed in two years. So, if promptly proceeded with, we are likely to see this effectually carried out long before its gigantic rival, the Channel Tunnel.

THERE seems to be much room for alteration for the better in the management of our dockyards. Our practical readers may have experienced, or at least can easily realise, the very great bar and hindrance to steady and effective work when the practical and technical chiefs are allowed no personal responsibility, but are entirely controlled by a head or heads which know nothing whatever of the practical work. This anomaly in management seems to exist in full force at present in our dockyards. There are under equal authority in our dockyards a ship-building officer, an engineer officer, a store-keeping officer, and a sail-making officer, with a naval officer over the whole as "manager." Such an anomaly could never exist with success in a private firm, and there can be little doubt that the effect on the Government establishment must be equally pernicious. The Controller of the Navy is now removed from the Admiralty Board, and the real authority which was once vested in the hands of the Chief Constructor by Mr. Childers when Sir E. J. Reed held that post, seems now to be dissipated in a committee and a president, one of the most unwieldy methods of management in the world. This seems to be all of a piece with the tardy recognition of the importance of the position of Chief Engineer on board ship. It may be unpleasant to the minds of admirals and captains of the old school to find their vessels now converted into gigantic engines of war, and thus to be now designed upon principles and constructed of materials of which they know nothing. But as the fact is now uncontrovertible and irrecoverable it would become them to more clearly and readily to recognize this fact, and gracefully to give the responsibility and management into the hands of those who know effectively how to deal with it.

WE see that an idea which was first promulgated some years ago has just been revived and further experiments been tried on a practicable scale. We refer to the operation of a submarine torpedo boat by electricity. A fairly successful test has just been concluded at Newport for the second time, a submarine torpedo boat having been run out from the port some distance and steered about with perfect ease, and brought back successfully to the starting point by an electric current operated from the shore. The danger to an attacking vessel if opposed by such a submarine vessel, invisible to the vessel it attacks, but entirely controllable from the shore, can hardly be exaggerated. It seems certain destruction to the ironclad. If the presence of sunken torpedoes, fired by contact or electrical discharge, can be considered a formidable defence, which they certainly are, the danger from such a submarine boat, directed at will against the attacking vessel from either side or the stem, is ten thousand times greater. In fact, the scientific and deadly means of destruction that are now being daily invented seem to point to a conclusion that naval warfare is no longer that of man to man or of courage against courage, but is of mechanical science against mechanical science. If once the direction, movement, firing of floating or submarine vessels by electricity becomes a practically accomplished fact, as it is a scientifically possible fact, we may picture to ourselves two opposing naval forces warring against each other at a distance by means of floating or submarine engines seeking each other's destruction by the directing force of electricity. The destruction on either side of these devilish inventions would practically decide the battle possibly without the loss of a man, as no ordinary ironclad could hope successfully to face such submarine infernal machines, and there would thus be but one resource for safety, namely flight.

IN our commercial marine, also, the march of scientific progress is moving fast enough to take all the breath out of the weather-worn mariners of a few years back. A steamer has just arrived in London from the Clyde, steered by electricity. The operation of the gear has been fully successful so far as the steering operations of the vessel, but an unexpected and new complication has arisen as affecting the use of electricity on board ship. The compasses were so affected as to be practically useless. If this is likely to be the case in all instances where much electricity is made use of, it will be a severe bar to the general introduction of electric lighting on board ship. We should hope, however, that some simple means of insulation from the effect of the induction of such currents, which we presume is the disturbing cause, will be introduced as a remedy, or possibly some substitution for the electrical needle as an indicator of the north pole may be invented which would not be affected by electric currents.

THE NEW DOCK AT LEITH.

THE new dock formally opened at Leith last week and henceforth to be known as the Edinburgh Dock, in honour of the Royal Duke who performed the ceremony, lies east of the Albert Dock, which is the most recent of the existing basins, having been completed in 1869. Access to it is obtained through the Albert Dock, and the connecting passage is spanned by a massive swing bridge, which is adapted both for railway and for ordinary traffic. The site, both of the Albert and of the Edinburgh Dock, has been reclaimed from the sea, and is protected by a solid reclamation bank upwards of a mile in length. This embankment is in itself a stupendous piece of masonry. The wall is 30 ft. broad at the base and 10 ft. at the top, and in its construction 100,000 tons of rubble and 8,000 cubic yards of ashlar and concrete were used. The breadth of ground reclaimed between the face of the embankment and the old foreshore varies from 1,250 ft. to 1,400 ft.—that is to say, it averages a quarter of a mile. The breadth of ground between the new dock and the sea is 225 ft., which affords ample space for sheds, lines of railway, and roadways. The view of the sea from this platform is at present shut out by a solid timber fence. When this has been replaced, as I believe it is intended to be, by a low parapet of stonework or concrete, there will be formed a splendid promenade, from which fine views will be obtained of both coasts of the Firth and of Inchkeith in the mid-channel, and on which pedestrians may enjoy refreshing sea-breezes. It will be in direct connection with the East Pier of Leith, which is at present one of the favourite Saturday walks of the citizens of Edinburgh. The pier and the embankment together will form a seaside promenade nearly two miles long, affording views of city and of coast almost unrivalled in variety and beauty. Eastward from the new dock the embankment encloses a space of upwards of 50 acres, which in the meantime will be filled in and given up to the railway companies—the North British and the Caledonian—but which may be utilized for additional dockyard accommodation, should that be necessary.

The new dock is 1,500 ft. long and 650 ft. wide; but there projects into it from the middle of the eastern end a jetty 1,000 ft. long and 250 ft. broad. At that end, therefore, the breadth of water on each side of the jetty is only 200 ft. But what is thus lost in water area is more than compensated for by the increased accommodation for berthing vessels and for wharfage and sheds. At the west end of the jetty there is a graving dock 300 ft. long. This is smaller than the Prince of Wales's Graving Dock in connection with the Albert Dock, which is 470 ft. long; but it will be a valuable addition to the conveniences of the port. The superficial area of the new dock is 16 2-3 acres. The Albert Dock, which is the largest of the existing docks, extends only to 10¾ acres. The wharfage of the Edinburgh Dock is, in linear measurement, 4,000 ft., or upwards of three-quarters of a mile. The masonry of the containing walls is of the most solid description, and is very handsome in appearance. The foundations rest on blue boulder clay—a formation eminently favourable in view of the requirements of the substantial superstructure. The northern side of the new dock will be appropriated to the coal traffic, which is expected to receive a new impetus from the convenience thus afforded to it. It is also intended to form special depots around the dock for the importation of grain, timber, flax, and other leading imports—an arrangement from which the trade of Leith will doubtless derive benefit. The whole works, including the railway undertakings, were estimated to cost £400,000. They have been carried on during the last five years by the trustees of the late Mr. Scott, under the personal superintendence of Mr. Scott, jun., Mr. Best, and their engineer, Mr. Clarke, C.E. Mr. J. Romilly Allen, C.E., representing Messrs. Rendall & Robertson, C.E., the engineers to the Commissioners, has all along worked harmoniously with the contractors. Mr. Andrew Gray was clerk of the works.

Including the Edinburgh Dock, there will now be five wet docks in connection with the port of Leith—three on the west side and two on the east of the inner harbour. All these docks have been constructed within the present century. What is familiarly known as the Old Dock was opened in 1806. The Queen's Dock, which is an extension of the Old Dock towards the west, was completed in 1817. After the adoption of free-trade policy, the commerce of the port increased rapidly, and the Victoria Dock, north of the Old Dock, was opened in 1852. During the next ten years the trade of Leith continued to grow "by leaps and bounds," and the Harbour Commissioners found it necessary to provide additional accommodation in docks and wharfage. They were forced, however, to encroach upon the sea, and the reclamation embankment now completed was begun, and the Albert Dock and the Prince of Wales's Graving Dock were completed in 1869. The additional accommodation thus provided was very soon found to be insufficient, and the great work inaugurated was commenced in 1874. When this rapid progress is considered, it will be thought that the Commissioners have only shown ordinary prudence in providing for the extension of the docks at no distant period.

INSTITUTION OF MECHANICAL ENGINEERS.

THE annual meeting of the Institution of Mechanical Engineers is to be held this year at Newcastle, on the 2nd, 3rd, 4th, and 5th August. The institution paid its last visit to Newcastle in 1869. Sir Wm. G. Armstrong was president that year, and he occupied the chair at the meetings, which were held in the Lecture Hall of the Literary and Philosophical Society. It is a remarkable coincidence that each of these visits to Newcastle should have occurred in the centenary years of great events in the history of mechanical science. The year 1869 was the centenary of the invention of the steam engine by James Watt, and the present year is the centenary of the birth of George Stephenson. Provisional arrangements for the meeting in August have been made, and the secretary of the institution, Mr. Walter R. Browne, has sent out a circular detailing them. By this we are informed that the reading and discussion of papers will take place, by invitation of the committee, in the lecture room of the Literary and Philosophical Society. The Wood Memorial Hall will be placed at the disposal of the members as a reception room by the Council of the North of England Institute of Mining and Mechanical Engineers. The North-Eastern Railway Company have kindly undertaken to provide special trains for the various railway excursions free of charge, and the chief works in the town and district will also be thrown open to the members. The proceedings will begin at ten o'clock a.m. on Tuesday, the 2nd of August, when the members will be received and welcomed by the Mayor (Ald. Angus) in the lecture room of the Literary and Philosophical Society. The address of the president, Mr. Edward A. Cowper, will follow, and at a quarter-past one the company will be provided with luncheon in the Assembly Rooms by the general committee. An hour later a special train will run to the works of Sir Wm. G. Armstrong & Co., at Elswick, and the inspection of them will occupy the time until four o'clock. Then the special train will go on to Newburn to give the visitors the opportunity of looking through the steel works of Messrs. John Spencer & Sons. Those who do not go to Newburn will proceed by special steamer from Elswick to the Swing Bridge, to see that structure. In the evening, the company will be the guests of Sir William G. Armstrong, at Jesmond Dene, where they will partake of dinner. From ten o'clock till half-past one on Wednesday, the members will be engaged with the reading and discussion of papers, and thereafter they will journey to Jarrow, where they will lunch at the works of Messrs. C. M. Palmer & Company. The inspection of the works and the return to Newcastle will fill up the interval between luncheon and the annual summer dinner, which will be held in the Assembly Rooms. Thursday, from ten in the forenoon till shortly after one, will be devoted to the reading and discussion of papers, and after luncheon in the Assembly Rooms the visitors will take a trip down the river. They will call, in succession, at the works of the Wallsend Slipway & Engineering Company, the lead works of Messrs. Cookson & Company, the Coble Dene Dock works, and finally at the new piers at the mouth of the Tyne. They will come back by special train from Tynemouth, and at half-past eight a conversazione will be held in the rooms of the Literary and Philosophical Society by invitation of the Society and of the General Committee. On Friday, the concluding day, there will be alternative excursions to Sunderland and Haydon Bridge. Those who choose to visit Wearside will arrive in Sunderland at half-past ten, and they will be shown over Monkwearmouth Colliery, Messrs. George Clark & Co.'s engineering works, the docks, the chain-testing works, and other places. Subsequently they will dine at the Queen's Hotel by invitation of the engineers of Sunderland. The Haydon Bridge division will depart from the Central Station at ten, and a few minutes after eleven they will reach the mines. Here, after having made their tour of observation, they will be entertained with luncheon by Messrs T. J. Bewick and partners. They will be back in Newcastle shortly after four. Visitors cards may be obtained on application, which will admit to the meeting, but not to works open for inspection, or to the excursions. The Local Committte, however, have arranged for the issue of a limited number of special visitors' cards, which will admit the holders to the excursions. Application for these will have to be made to the office, 10, Victoria Chambers, London, S.W. The following gentlemen constitute the Local

Executive Committee:—Mr. Percy G. B. Westmacott (chairman), Mr. John A. Haswell, Mr. F. C. Marshall, Mr. R. S. Newall, Mr. William Boyd, and Mr. J. Cartwell Ridley. The two last-named gentlemen are the honorary secretaries.

SHEERNESS DOCKYARD.

ON Wednesday, July 20th, the members and associates of the Society of Engineers visited the forts and dockyards at Sheerness, by special permission of the Secretary of State for War and the Lords Commissioners of the Admiralty. There were present about 120 members and associates and their friends, the party including Mr. Charles Horsley, president; Mr. Robert P. Spice and Mr. Joseph Bernays, past president; Mr. Jabez Church, vice-president; Mr. Robert Berridge, Mr. William Schönheyder, and Mr. Perry F. Nursey, members of council; Mr. Alfred Williams, honorary secretary and treasurer; and Mr. Bartholomew Reed, secretary. The party proceeded from London by special steamer, and were received on the dockyard landing-stage by some of the authorities, by whom they were courteously conducted over the yard and works. This dockyard is used for building, fitting, and repairing small cruising vessels, and comprises five dry docks, one closed basin, and two open or tidal ones. About 1,700 men are employed on the general work of the yard, and at the present time there is one vessel—the *Satellite*—in course of construction, one—the *Caroline*—in course of fitting out, and four are under repair. The visitors were first conducted over the engine-fitting shop which has two extensive galleries, one devoted to light fitting work, and the other to pattern making. The brass foundry and coppersmiths' shop were next inspected, after which two beam engines of 50-horse power each were shown. These engines are used for pumping out the docks, and have been on the establishment for 60 years. In the boiler shop the visitors found a number of boilers under repair for the various vessels in course of refitting, among them being those of the *Sylvia*, surveying vessel. The yard smithy contains 60 forges, several steam-hammers of various sizes, and gives employment to 170 hands. A small galvanizing shop was visited on the way to the timber shops, where wood-working machines, both heavy and light, were seen in operation preparing the timber used in the building and fitting of the ships. The fitting shop for shipwork and the chain cable testing-house were inspected on the way to the *Satellite*, which is in course of construction. This vessel is a composite sloop and will carry eight Armstrong guns of the new pattern. She is 200 ft. in length, with an extreme breadth of 38ft., and a moulded breadth of 37ft. Her draught of water is 12ft. 9 in. forward, and 15 ft. 9 in. aft, with a displacement of 1,420 tons. She will be propelled by a single screw driven by engines of 900-horse-power. The building of the *Satellite* was commenced on the 4th of October, 1880, and she is to be launched on the 13th of August. From the dockyard the visitors proceeded to inspect the fortress at Garrison Point, which commands the entrances to the Thames and Medway. This fort mounts 44 guns, ranging from the 9-inch gun of eight tons to the 12·5 inch gun of 38 tons, and including the 10-inch gun of 18 tons. After inspecting the *Hydra* turret-ship, carrying four 18-ton guns, the visitors returned to London, having passed a pleasant and profitable day.

AN ACCOUNT OF EXPERIMENTS MADE BY A BOARD OF UNITED STATES NAVAL ENGINEERS WITH SCREW PROPELLERS OF DIFFERENT MATERIAL AND DIMENSIONS APPLIED TO THE UNITED STATES FISH COMMISSION'S STEAMER "LOOKOUT" WITH THE HULL COPPERED AND NOT COPPERED.

By Chief-Engineer ISHERWOOD, U.S. Navy.

IN the refitting at the Washington, D.C., navy-yard, of the United States Fish Commsssion steamer, *Lookout*, seven screws were adapted to her, differing in diameter, pitch and fraction of the pitch used, with the view of experimentally ascertaining the best proportions of these for that particular vessel. Two of the screws being of cast iron and the remaining five of cast brass, they furnished an opportunity for observing the comparative effect of these two metals upon the economic efficiency of the screws. Further, as the vessel's bottom was covered with rolled copper during the experiments with two of the screws, while it was not so covered during those with the remaining five screws, but exposed to the water only the wooden surface of a vessel in the usual condition for coppering, the occasion was afforded to determine the effect of such coppering or want of coppering upon the resistance of the hull.

The experiments with these screws were made by a Board of Chief-Engineers of the United States Navy, which reported the data to the Bureau of Steam-Engineering of the Navy Department. The writer has taken these data, corrected and re-arranged them, and from them has made the calculations and deductions that will be found in this paper, none of which are in the Board's report.

The experimental deductions contain two novelties, namely, the effect upon the economic efficiency of screws due to their being constructed of cast brass or of cast iron, and the effect upon the resistance of wooden hulls due to having their bottom coppered or of presenting to the water a wooden surface in the usual state preparatory to receiving the copper; or, in other words, the determination of the comparative resistance to motion in water of hulls having their immersed wetted surface of copper or of planed wood. In the absence of other experiments on these points, the present ones will be of interest, taking care to discriminate that the comparison holds strictly true only for the exact experimental conditions, any variation of which would consequently vary the comparative results; but, although the experiments determine these results quantitatively for only the particular cases on trial, yet they remain qualitatively true for all cases.

Taking the resistance of a hull as composed of the resistance of its immersed wetted surface to the water; and of the resistance of the water to displacement by it, that is to say, the resistance of water to being elevated from the centre of gravity of the greatest immersed transverse section of the hull to whatever height above the water-level it may be forced by the progress of the vessel; there follows that the ratio of these two resistances will vary according to the form or model of the hull. If the hull, of given lineal dimensions, be very sharp, the larger portion of its resistance as a whole will be composed of its skin resistance or that of its immersed wetted surface to the water, while the remaining smaller portion is composed of the resistance of the water to displacement. And, *vice versâ*, if the hull be of very full form, the larger portion of its resistance as a whole will consist of the resistance of the water to displacement, while only the remaining smaller portion is due to the skin or wetted surface resistance. In the case of the *Lookout*, the hull was very sharp, exposing a great extent of immersed wetted surface comparably to its displacement; consequently the difference between the resistances of the two kinds of surface—rolled copper and planed wood—will be proportionally more marked in her than in the cases of vessels with fuller forms. However hard and smooth a wooden surface may be made out of water, yet when immersed it will become water-soaked and soft, the small exposed fibres of the wood separating, rising, and forming a delicate hairy coating, offering much more resistance to water than the original hard, plane surface from which they arose.

It is to be regretted that the experiments were so few; they might easily have been extended by cutting off two of the four blades of the screws, by successively reducing their diameters and lengths, &c., which modifications could have been executed at little cost, as the screws did not exceed 5 feet in diameter, a size readily handled yet large enough for reliable results; but, as the vessel was not entirely at the command of the Bureau of Steam-Engineering, only such trials were available as could be made without interfering with her other uses.

The experiments do not show any superiority of cast brass over cast iron for the material of the screw; from which may be inferred that, per unit of surface moving at equal speed, the resistance of the water to the cast iron surface is no greater than to the cast brass surface. Also, that the less direct resistance of the thinner cutting or forward edges of the blades of the brass screw was not sufficient to produce a sensible effect on the economic result. The much less cohesive strength of cast iron than of cast brass requires the blades of screws made of the former metal to be much thicker for equal strength than those made of the latter metal; and in the case of the experimental screws, the cast iron blades were about two and a half times thicker than the cast brass ones. Of course, the thicker blades must be attended with more direct resistance than the thinner ones, but the edges, forward and aft, of all blades are so acutely bevelled that any difference due to this cause seems to be too slight to affect the result in a marked manner.

HULL.

The *Lookout* was constructed of wood for a steam yacht, and had a light schooner rig. The bottom was uncoppered during the trials with screws *A*, *B*, *C*, *D* and *E*; but it was coppered during the remaining trials with screws *F* and *G*.

The following are the dimensions and proportions of the hull corresponding to the draught of water which was maintained without sensible variation during all the trials:—

Length on water line from forward edge of rabbet of stem to after side of the sternpost		96 feet.
Greatest breadth on waterline		13 ft. 6 in.
Extreme breadth		16 feet.
Draught of water from bottom of keel	Forward	2 ft. 9 in.
	Mean ...	3 ft. 8 in.
	Aft ...	4 ft. 7 in.
Depth of keel below lower edge of its rabbet	Forward	6 in.
	Mean ...	1 ft. 2 in.
	Aft ...	1 ft. 10 in.
Mean depth of hull from water-line to lower edge of rabbet of keel		2 ft. 6 in.
Area of the greatest immersed transverse section		25·28 sq. ft.
Area of the water-line		861·44 sq. ft.
Displacement (35 cubic feet per ton)		42·87 tons.
Displacement per inch of draught at water-line...		2·051 tons.
Ratio of length to breadth on water-line... ...		7·1111.
Ratio of the greatest immersed transverse section to its circumscribing parallelogram		0·7490.
Ratio of the water-line to its circumscribing parallelogram		0·6647.
Ratio of the displacement to its circumscribing parallelopipedon		0·4631.

ENGINE.

The vessel had one vertical, direct-acting, compound, condensing steam engine, with the two cylinders placed side by side, and acting on cranks at right angles to each other.

Diameter of the small cylinder	12 inches.
Diameter of piston rod of the small cylinder ...	1½ inches.
Net area of the piston of the small cylinder ...	112·2140 sq. in.
Stroke of the piston of the small cylinder ...	16 in.
Space displacement of the piston of the small cylinder, per stroke	1·0390 cu.ft.
Diameter of the large cylinder	20 inches.
Diameter of the piston rod of the large cylinder	1½ inches.
Net area of the piston of the large cylinder ...	313·2764 sq. in.
Stroke of the piston of the large cylinder ...	16 inches.
Space displacement of the piston of the large cylinder per stroke	2·9007 cu.ft.
Ratio of the space displacement of the piston of the large cylinder, per stroke, to that of the piston of the small cylinder	2·97178

BOILER.

There was one cylindrical boiler, with cylindrical furnaces, and horizontal fire tubes returned over them. A large portion of the steam room was in a steam-chimney or drum placed above the shell and traversed by the chimney, so that the steam in the drum was, in a measure, superheated by the escaping hot gases of combustion.

Diameter of the boiler shell	7 feet.
Length of the boiler shell	8 feet.
Diameter of the steam-chimney	4 ft. 6 in.
Height of the steam-chimney	5 ft. 6 in.
Number of furnaces...	2
Diameter of the furnaces	2 ft. 4 in.
Length of the grates	5 feet.
Area of grate surface	23⅓ sq. ft.
Area of water-heating surface, calculated for outside of tubes	519 sq. ft.
Calorimeter, or aggregate cross area of tubes, for draught	3·14 sq. ft.
Steam room in boiler shell and in steam-chimney	94·54 cu. ft.
Square feet of water-heating surface per square foot of grate surface	22·2429.
Square feet of grate surface per square foot of cross area of tubes	7·4310.

SCREWS.

The screws experimented with were seven in number, and are designated by letters from *A* to *G*, both inclusive. In the Tables hereinafter given, the columns headed with these letters contain the data and results of the experiments made with the screws of corresponding letters.

All the screws were of cast brass with the exception of screws *B* and *G*, which were of cast iron, and had blades about two and a half times thicker than the brass ones.

All the screws had four blades and a uniform pitch, which varied for the different screws from 7·50 to 9·08 feet. The mean fraction used of the pitch varied also from 0·1994 to 0·5736. The diameter of all the screws, except *A* and *F*, was 5 feet; that of *A* was 4·6458 feet, and that of *F* was 4⅔ feet.

When the vessel was at rest, a small portion of the 5 feet diameter screws protruded above the water; but when the vessel was in motion at the experimental speeds, all the screws were submerged, owing to the dropping of the stern.

The following Table shows the principal dimensions of the screws:—

Designation of the screws.	Diameter, feet.	Pitch, feet.	No. of blades.	Greatest length of screw in direction of axis. Feet.	Projected area of blades on a plane at right angles to axis. Square feet.	Helicoidal area of blades. Square feet.	Mean fraction used of the pitch.
A	4·6458	8·400	4	0·9167	5·4551	7·9447	0·3325
B	5·0000	7·500	4	1·1875	10·1693	13·5266	0·5283
C	5·0000	7·500	4	0·5208	5·2457	6·7860	0·2703
D	5·0000	8·625	4	0·4461	3·8697	5·3470	0·1994
E	5·0000	9·000	4	0·8125	6·8975	9·3407	0·3549
F	4·6667	9·000	4	0·8125	5·9659	8·6850	0·3539
G	5·0000	7·900	4	1·2708	11·0098	14·8453	0·5736

(*To be continued.*)

THE RELATIVE CORROSION OF IRON AND STEEL.*

By Mr. WILLIAM PARKER, Chief Engineer-Surveyor of Lloyd's Register, London.

(*Continued from page* 78.)

BRIGHT DISCS.

TABLE I. gives the loss of metal per square foot per annum. This was obtained by dividing the total loss of weight of each disc by its exact area (about ¼ of a square foot) and by the total period during which each set was exposed, which includes the time that the boilers were empty or not in use. Table II. was compiled from Table I. by dividing each of the losses in the different columns by the loss of the respective Lowmoor plates, so that the different sorts of iron and steel can be readily compared. Looking at Table II., under the heading of "Cold Water," and in the third column, which gives the mean values of the relative losses in the sea and bilge water, it will be seen that there are but two metals—Bowling iron and Messrs. Brown's steel—which corroded more than Lowmoor iron; and although the average loss of steel is a little greater than that of iron, the difference is so slight that for practical purposes it is safe to assume that bright steel exposed to the sea or bilge water corrodes no faster than bright iron, especially than the better qualities of iron. When exposed to the atmosphere, although there is no great difference between the common and the better sorts of iron, the steel appears to have lost considerably more than either

---

* Read at the Spring Meeting of the Iron and Steel Institute

Lowmoor or any other iron; and the same is the case with those discs exposed to the action of boiler water with or without zinc. But although the absolute losses of both iron and steel is least, the relative difference of losses of steel and iron is greatest in the boiler in which zinc is used. Here the steel has lost about 50 per cent. more than Lowmoor iron, and Lowmoor iron 50 per cent. more than Bowling iron, or 40 per cent. more than the average of the other irons. On referring to Table I., column 4, it will be seen that the average losses per square foot are very small, and that the greatest loss of steel (Messrs. Brown's) in the boiler with zinc was less than the smallest loss of iron (Bowling) in the air, and far less than the Bowling iron in the other two boilers.

TABLE I.

Absolute Loss of Iron and Steels in Pounds per Square Foot of Bright Surface per Annum.

	Cold Water.		Atmosphere, London.	Boilers.		
	Sea. B.	Bilge. C.	A.	Zinc in Boiler. D.	Collier Boiler. F.	P. and O. Boiler. E.

Note.—A loss of 1 pound per square foot per annum is equal to an average loss of $\frac{1}{40}$th inch of thickness per annum.

Returning to Table II., we observe in column 9 that the steel with one exception, has on an average corroded only about 1 per cent. more than the Lowmoor iron, which has always been considered as amongst the most suitable for the internal portions of boilers, and which has corroded about 20 per cent. more than the ordinary irons. So that, although the present experiments confirm the prevailing impression that bright mild steel does corrode faster than iron when we get from cold sea-water to the condition of a marine boiler, the difference is not so great as to establish the matter beyond question. I have here specimens of the steel and iron discs out of the boiler containing zinc. You will observe that the surface of these specimens is only a little rough, and that the corrosion is very uniform, which is the case with all the bright plates exposed in this boiler. The plates exposed to the atmosphere are slightly rougher, but also uniform, while those suspended in the boiler of the Peninsular and Oriental Company's vessel are roughly and more irregularly corroded. It is not a little surprising to find that it is only amongst the discs exposed in this boiler and those exposed to the bilge water that any deep pitting has taken place. There were four cases, of which I produce two specimens, which are very distinctly pitted. These were Farnley iron and Messrs. Brown's steel. The one contains a pit mark about 1-16th of an inch deep, and the others pit marks not quite so deep. The plates submerged in the sea were irregularly attacked, and rather patchy. Those exposed to the bilge water looked still worse, the black plates now and again containing pit marks, and the fibres of the iron in many cases being distinctly visible. The plates exposed in the boiler of the coasting vessel had accidentally come adrift, and the insulation was thus destroyed within the last

TABLE II.

ten weeks of their immersion, and they do not show the action of the water so distinctly as in the other cases. No pitting has occurred, but the structure of the iron has in one or two instances been conspicuously brought out. The Lowmoor disc placed in this boiler also showed very marked projections, one of which, about two square inches in area, contained a thin red scale of what proved by analysis to be copper. The hardening of the plates, by punching the numbers, in no way affected the corrosion of the bright discs, but the glass ferrules protected the part of the disc with which they were in contact when exposed to the atmosphere and bilge water. Curiously enough, however, in some of the cases in the boiler containing zinc, and in the sea, there was found to be considerable extra corrosion in the neighbourhood of the glass.

Note.—The discs analysed were the bright ones of series F, which, as already stated, was suspended in a boiler supplied with water from a point in the Tyne where it is probably acidulated by the refuse from one of the local copper works.

Black Discs.

With the black discs the glass had also protected parts of those discs subjected to the influence of bilge water and the atmosphere, while it had caused strong local corrosion on every one of the discs immersed in the sea and on about half of those exposed in the boiler containing zinc; and perhaps a still more curious circumstance is that almost throughout the experiments the glass ferrules wasted more than the metals. The stamping of the numbers, which, unavoidably caused some of the scale off, had an injurious effect on the plates exposed in the sea and the bilge, although the local corrosion from this cause was only slight in all the other cases.

Table III. shows the results of the analyses of the several bright discs contained in series (F).

Mean loss of scale due to stamping and exposure exclusive of Lowmoor	·38	·73	·74	·54	1·00	·96	—

To enable us to compare the corrosions of the black plates, it is necessary to divide the loss they sustained not by the total surface of the discs, but by the surface of the bare metal only. The percentage of exposed to total surface of each disc was therefore ascertained as nearly as possible, and will be found in Table IV. A perusal of this Table shows that, neglecting Lowmoor iron, which lost almost all its scale, the least scale has come off those discs immersed in the sea, namely, about 30 per cent; next comes the series D, which was exposed in the boiler containing zinc, with 50 per cent., followed by the two sets exposed to the atmosphere, and in the bilges with an average of 70 per cent., while the plates in the boiler of the Peninsular and Oriental steamer lost 95 per cent. Those suspended in the boiler of the coasting vessel lost all their scale, but this is easily accounted for by the fact that the glass ferrules broke during the last ten weeks of the exposure, thus allowing the discs to rub against each other. Taking the mean values of the figures in columns 1, 2, 3, and 4, it will be seen that the Lowmoor iron has lost all scale; that Bowling iron, Leeds Forge iron, Parkhead iron, and Brown's steel have lost about 80 per cent.; Farnley Iron and Steel Company of Scotland steel about 70 per cent.; Skerne iron and Bolton steel about 55 per cent.; and Taylor's iron and Landore steel about 40 per cent. It should be mentioned, however, that in stamping the numbers before the experiments it was observed that the Lowmoor scale appeared to be the softest, and fell off more easily than any other, while the other scales adhered better, but with different degrees of tenacity. With the help of Table IV., and the accurately ascertained loss of each black sample, and also the losses per annum per square foot of bright samples, as given in Table I., we are able to compare the average depth of corrosion of the bright discs, and that of the black discs where the scale has been removed. These results are given in Table V.

TABLE V.

RATIO OF AVERAGE DEPTH OF CORROSION OF BLACK DISCS TO BRIGHT DISCS.

Without knowing how long the scale had been off, it is of course impossible to form a correct measure of the rate at which the black oxide might have been acting galvanically upon the neighbouring bare patches, but the comparison is worth making, so far as it goes, and it certainly tends to confirm the belief mentioned by Mr. Barnaby and others, that a rather strong galvanic action does go on between the scale and the patches of bare steel in its neighbourhood. Looking to the importance of this point, it is to be hoped that it will be further followed up and scientifically analysed, as it seems to be, from these experiments, of quite as much importance as has been attributed to it. I have now endeavoured to lay before the meeting the results of the series of experiments which it has been my privilege to make. I do not for a moment pretend to be able to account for all the peculiarities that have arisen. Some degree of capriciousness was to be expected from those plates on which the scale was left, but I must confess I was hardly prepared to see so much difference between different steels and between different irons under precisely similar conditions, as proved to be the case. It would, perhaps, not be far wrong, speaking generally, to say that the different pieces of iron differed as much among themselves as they did from steel; and certainly the effect produced on my mind, after carefully weighing the results of the experiments, has not been to raise any apprehension that steel boilers or steel ships are likely in the future to corrode to any serious extent more rapidly than iron. Having made these experiments, however, I desire to say that I do not think undue importance should be attached to any experiments of the kind made on a small scale. The most they can do is to indicate tendencies, and perhaps suggest remedies and precautions earlier than actual experience, which necessarily takes some years to accumulate when a new material is placed under trying conditions. The only real test, however, and the only one that will be finally accepted, is that of practical experience with the boilers themselves. We have at the present time some 1,100 marine steel boilers running, the majority of which come periodically under the inspection of the Engineer-Surveyors of Lloyd's Register, and although they have received instructions to give these boilers special attention and to note carefully any peculiarities they may discover, the accounts I have received from them down to the latest, go to show that the steel boilers behave, in respect to corrosion, about as well as iron boilers. In one or two vessels also, where an iron and a steel boiler are working under identical conditions, there is nothing to point to the conclusion that the iron will outlast the steel one. Greater irregularity in the corrosion of the steel is reported, and I am inclined to the belief that this is due, even to a greater extent than shown in the experiments, to the unequal action of the scale, and if it should be found necessary hereafter to remove the scale, the difficulties in the way would not be great, and much of the irregularity and pitting would doubtless be removed. This I know is being done to a limited extent in boilers. The Admiralty also have taken steps to remove the black scale from their ships, and I have heard of at least one firm intending to follow their example. At any rate, I feel sure this meeting will hear with satisfaction that neither from the series of experiments which I have described, nor from our daily experience up to the present time, is there any reason to believe that the question of corrosion is likely to form a bar to the extended use of steel for marine boiler-making purposes. Difficulties may arise, and some unexpected results may be found, but the difficulties will, in my opinion, be easily removed, and the members of this Institute will, I am sure, welcome any one who will lay before them unexpected results, and will assist him in obtaining an explanation of them.

MILD STEEL IN FRENCH ARSENALS.

On the Use of Mild Steel for the Construction of the Hulls of Ships in the Arsenals of the French Navy.

By M. MARC BERRIER FONTAINE, Member.

(*Continued from page* 88.)

As regards the calculations of tensile strength, it appears from the results of the tests which have been already carried out in considerable number, that we may adopt the mean figure of 48 kilogrammes per square mm. as representing the ordinary breaking strain of steel plates and moulded bars such as are actually used in the French Navy. The ordinary breaking strength of the iron plates and moulded bars of ordinary and common quality which are delivered to it cannot, on the other hand, be regarded as greater than 36 kilogrammes per square mm. at the outside. For iron we generally use a factor of safety of 6, that is to say, that we look upon 6 kilogrammes per square mm. as the limit of the load that we consider proper to put upon it in shipbuilding. Using the same factor for steel, we reckon that plates and moulded bars of this metal may be safely loaded with 8 kilogrammes per square mm. The limiting loads of 6 kilogrammes and 8 kilogrammes per square mm., which have just been mentioned, are to one another as 1 :

1.33, consequently the inverse ratio of 1 to 0.75 indicates the reduction of thickness, and, therefore, of weight which the substitution of steel for iron allows us to introduce into the plates and moulded bars which we use. This corresponds to an economy of 25 per cent. in the weight of a hull of given dimensions and form. In order to take account of the loss of strength experienced during the work—a loss which, as we know, may well be of greater relative importance in steel than in iron—and in order to take account of the existence of an inferior limit below, which we cannot reduce the thickness of steel plates without risking their buckling, and although there does not exist any general formal rule about this, the constructors of the French Navy, in agreement with the authorities of Lloyd's Registry, think that it is not safe to reckon on a final saving of more than 20 per cent. in the replacing of iron by steel in the weight either of the whole hull or of any part of it. The total amount of this reduction being thus fixed, the French Navy has never experienced the slightest difficulty in procuring plates and moulded bars of steel of suitable thicknesses or scantlings to secure this saving of weight. As several engineers have very justly remarked at the preceding meetings of the Institution, if the reduction of 20 per cent. were to be uniformly and separately applied to the thickness of each of the pieces which entered into the construction, doubtless there might be some difficulty in getting at it; but it is easy in the practical application of this reduction to introduce numberless compensations, and consequently to reach the desired reduction on the whole of the construction. In accepting the tenders for the French Navy, care is always taken to specify for the plates the weight per square metre, and according to the thickness in millimetres, and for moulded bars the weight per metre run; these fundamental weights being always calculated on the supposition that the plates and moulded bars of steel have a mean specific gravity of 7·8. We specify, moreover, that the weights thus indicated are never to be exceeded. The only departures which are permitted are in defect, and of this the following are the limits generally adopted: For moulded bars of every section, 5 or 6 per cent., accordingly as their scantlings are greater or less; for plates of 1½ mm., 12 per cent., this margin of 12 per cent. diminishing by 1½ per cent. for every mm. of extra thickness up to 5 per cent. for plates of 15 mm. and all greater thicknesses. It is finally stipulated that these thicknesses are only pointed out as mere approximate guides. These arrangements practically come to ordering both plates and moulded bars by weight and not by thickness. The French makers, whose interest it is to keep as nearly as possible to the higher limit pointed out to them in each case, seeing that the plates and moulded bars are paid for by their actual weights, have, like their colleagues in England, never found the slightest difficulty in executing orders given to them under these conditions.

A very important question, which has already been discussed during the preceding meetings of the Institution, especially in 1878, in the able communication of Mr. Martell, "On Steel for Shipbuilding,"[*] is one that concerns the interests that shippers may have from a strictly commercial and economical point of view in exchanging steel for iron in the construction of their ships. The examples quoted by Mr. West show clearly that the actual cost of a ship built in steel was still, three years ago, considerably greater, in the proportion of 9 to 8 nearly, than that of a ship of similar form, and the same external dimensions, built of iron. The choice of steel for the construction of a ship could thus only bring about under these conditions, as the practical result, an economy, as Mr. Martell has endeavoured to explain to us, from the greater profits which such a ship would bring if built in steel, thanks to a larger proportion of total weight remaining disposable for cargo. The discussion which took place brought out that, at any rate at the time we are speaking, of the practical advantage that could thus be realized by shippers was still far from being uncontested. Without entering afresh into the discussion of the very different opinions which have been held on this point, I will content myself with bringing under notice how much this divergence of views loses its importance if we look to the future, and that undoubtedly the immediate future. It is, in fact, permissible to predict, almost with certainty, that the price of plates and moulded bars will continue to get lower and lower pretty rapidly, and that consequently the time will soon have come when the cost of a ship built in steel will not exceed that of a ship of similar form, and of equal dimensions, built of iron. We are even free, having regard to the increasing experience, skill, and ability of workers in steel, to predict that in the not very distant future, plates and moulded bars of steel (of which the manufacture requires even now, after all, neither more nor less handiwork nor more fuel than that of plates and moulded bars of iron) will ultimately cost no more for steel than for iron. The advantages of the use of steel in the construction of merchant ships will not then fail to be completely appreciated by all charterers without exception, who will be in a condition to profit by it to secure ships presenting in comparison with ships of iron of similar form and equal external dimensions the following various causes of superiority: a lower cost price, a much lower weight of hull, and consequently an effective paying tonnage increased in the same proportion, and finally a hull built of more ductile material, and therefore less liable to receive serious injury from grounding, from slight collisions, and so forth, from which no ship can be guaranteed. For the French Navy, which uses exclusively iron of the best quality, and of which the price is considerably greater than that of the iron employed in building merchant ships, the time has already come at which the hull of a steel ship comes out at a lower price than the hull of a ship of similar shape and equal dimensions, built of iron. This result is due to the considerable reduction that the price of steel has undergone within eight years, and in consequence of which the prices of steel plates and angle irons are now sensibly equal to or even rather below those of iron plates and angles. This does not quite hold, it is true, for steel bars other than angle irons. The price of these is still higher in the proportion of 1·76 to 1, or thereabouts, than that of similar bars of iron. That is an anomaly which I find some difficulty in explaining, but which time and the increased competition between the different works will doubtless not be long in causing to disappear. However this may be, the moulded bars we are speaking of only enter a very little into the total weight of a ship, and their higher actual price is even now an insufficient set-off to the savings which result on the whole of the construction, from the replacing of iron plates and angles by steel plates and angles, of which the price is considerably lower than formerly, and whose total weight, moreover, may be 20 per cent. less.

(*To be continued.*)

TRIAL TRIP OF THE "ALMIRANTE BROWN."

THE *Almirante Brown* is a twin screw armour-clad corvette, built by Messrs. Samuda Bros. for the Argentine Republic. She was launched 6th October, 1880, and fitted with engines and boilers by Messrs. Maudslay & Co., Lambeth.

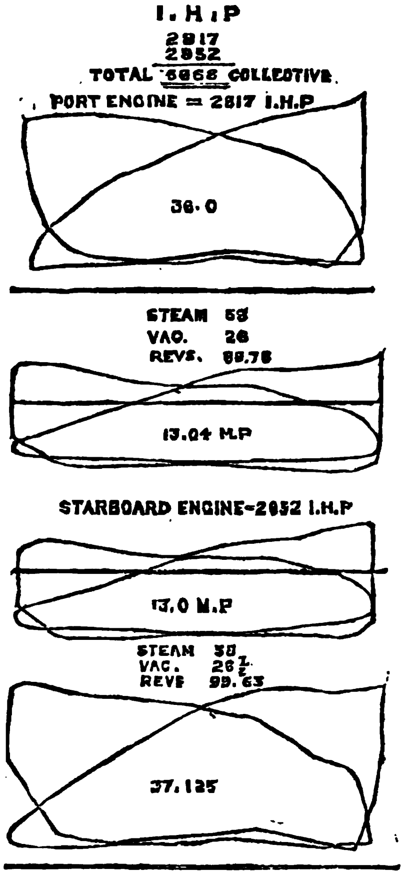
She is a vessel of moderate size, combining all the latest improvements in construction, armour, and armament. The hull of the vessel is built entirely of Siemens' steel; the armour is "compound" or steel-faced, consisting of an armour belt 9 in. thick at water-line, and 6 in. thick below water, extending 120 ft. in length, and protecting the engines, boilers, and magazines. There are cross bulkheads at the ends of the belt, which reach from 4 ft. below the water line to the main deck. Above the main deck amidships is an armour-plated battery with double embrasures at the fore end, and containing in all six guns. The thickness of armour on the battery sides is 8 in. and 6 in.; that on the ends 7 in. and 6 in. The armour plates on the belt and battery are worked on a teak backing averaging 10 in. thick. The armour plates are secured to the vessel with bolts and nuts, screwed from the inside, and so arranged as not to wound the steel face of the armour. Horizontal armour of steel plates 1½ in. thick is worked from the battery to the ends of the vessel, forming a shell-proof and watertight deck 4 ft. below the water, protecting the steering apparatus, &c. The bottom of the vessel is covered with teak planking 3 in. thick, and zinc sheathing as a protection against fouling. The vessel is fitted with a double bottom, and divided by transverse bulkheads and steel decks into numerous water-tight compartments. The vessel is rigged with two pole masts, giving an area of sail of 10,000 square feet.

The ship is 240 feet long between the perpendiculars, 50 ft. beam, and 21 ft. 11 in. deep from the underside of the main deck to the garboard strake. She can stow 650 tons of coal, sufficient to supply the vessel when steaming at a moderate speed—say of 10 knots per hour—for eighteen days, and enabling her to travel 4300 miles.

Her armament consists of six 8 in. breech-loading 11½-ton guns in battery, capable of throwing a projectile of 180 lb. These guns are so placed that they can be fired in a line parallel with the line of keel, one 8 in. 11½-ton gun at bow, one 8 in. 11½-ton gun at stern. These guns are all constructed on the latest breech-loading principles, and mounted on wrought iron carriages and slides, manufactured by the makers of the guns, Sir William Armstrong & Co., of Elswick. Four 12-centimetre breech-loading guns with hydraulic Albini carriage and slide on upper deck, and two ditto on battery deck; two 9-pounders for boats and field carriage for ditto for use on shore. She is propelled by two pairs of inverted compound surface condensing engines; high-pressure cylinder 52 in. diameter, low-pressure cylinder 90 in. diameter; stroke 3 ft. 3 in.; diameter of crank shaft 13¾ in.; of crank pins 14 in.; length of connecting rod, 6 ft.; steel piston rods 8¼ in. diameter; one air pump to each set of engines 41 in. diameter; two feed pumps ditto 6 in diameter, two bilge pumps ditto 7¼ in. diameter; condensing surface 9000 square feet. Each pair of engines works its own screw, and is fitted in a separate engine-room. The boilers are eight in number—oval tubular. The boiler-room is divided into four separate water-tight compartments, and the machinery is so constructed that should three of the compartments be disabled the other compartment will remain intact with its complete set of pipes and valves. There are eight boilers and twenty-four furnaces. The diameter of the furnaces is 3 ft. 3 in. There are 283 tubes in each boiler 3 in. diameter, and 6 ft. 6 in. between tube plates. The grate surface is 507 square feet; the heating surface 13,674 square feet; the pressure on the safety valves 65 lb. per square inch. The engines are provided with Durham's patent velometers for preventing racing at sea.

---

[*] Transactions Institution Naval Architects, vol. xix., 1878, pp. 7, *et seq* See also the discussion by Mr. C. H. Wigram, Mr. W. Denny, and others pp. 24, &c.



On her measured mile trial at Maplin sands, on 14th June, 1881, she attained the following results:—

Draft forward 18·6 } = 19·2 mean and 4237 tons displacement
Draft aft 19·10 ... } and 833 ft. M. S.

Runs.	Knots.

			56·167 + 4 = 14 042

Revolutions ... ... 90·05 Indicated horse-power 5400

On her six hours' trial of 16th inst., the vessel being in all respects as before, the mean indicated horse-power was 5470, revolutions 89½. So that more power and more revolutions were maintained continuously for six hours' time, than on measured mile.

The detailed particulars of the ship's six hours' run may be thus stated:—The vessel left the Royal Albert Docks on Monday, June 15th, about 12 noon, and proceeded down the river at an easy speed to Sheerness, where she was anchored and lay for the night. The stokers for the trials were lent from Chatham Dockyard by the Admiralty, and were sent on board early on Tuesday morning, June 16th, in charge of an engineer and doctor. His Excellency Senor Manuel Garcia, the Argentine Minister, and a numerous party, including Admiral Sir Houston Stewart, Mr. J. D. A. Samuda, Mr. Joshua Field, Commodore Cordero, Captain Urubey, the secretary of the Argentine Legation, Mr. J. Wright, engineer-in-chief of the Admiralty, Mr Telford Field, Mr. G. Duncan, Mr. Walter Maudslay, Mr. W. Hales White, Assistant Constructor of the Navy, and designer of the vessel, Mr. Kelson, and a number of gentlemen connected with the Argentine Government, left Victoria by special train soon after eight, reaching Sheerness about half-past nine. The vessel started as soon as all were on board, and proceeded to the measured mile at the Maplin Sands. Six runs were made, with the following results:—

	Time.	Speed.	1st Means.	2nd Means.	
	m. s.	Knots.			
1st mile	3 48	15·789			
			13·914		
2nd „	4 59	12·040		14·021	Mean revolutions, 90·05
			14·128		
3rd „	3 42	16·216		14·158	Mean I.H.P. of the six runs, 5399·65
			14·189		
4th „	4 46	12·168		13·997	
			13·806		
5th „	3 53	15·450		13·991	
			14·147		
6th „	4 39	12·903		56·167 + 4 = 14·042 knots mean [speed	

It will thus be seen that the maximum power developed during the trial was 5790·79 horses—1290 horse-power over the contract (4500). On both occasions the engines were in charge of Mr. Duncan and Mr. Warriner. The working of the machinery was perfect, and although driven for seven hours at the highest speed no water service was required, nor was there any sign of hot bearings. At the conclusion of the trial the vessel proceeded to Greenhithe, where she anchored for the night. Nothing could be more satisfactory than the manner in which the machinery worked throughout, the average horse-power developed being over 900 in excess of the contract.

Mr. J. D. A. Samuda, in presiding at the luncheon on board, gave the toast of "*The Almirante Brown*," and stated that the corvette was the first vessel built entirely of steel, and at the same time having a coating of steel-faced armour. Nothing has hitherto been built of the same displacement, and with the same power of artillery as the *Almirante Brown*, which has attained the speed, averaged in the six runs, of over 14 knots.

The corvette then returned to her moorings at Sheerness, and lay there until Thursday, June 16th. She started again at half-past ten on that morning, and steam having been got up to the full pressure the half-hourly observations were commenced at 11·15, with the following results:—

Half-hours	Boiler Pressure.	Revolutions.		Vacuum.		Indicated H. P.		Total I. H. P.
		Star.	Port.	Star.	Port.	Star.	Port.

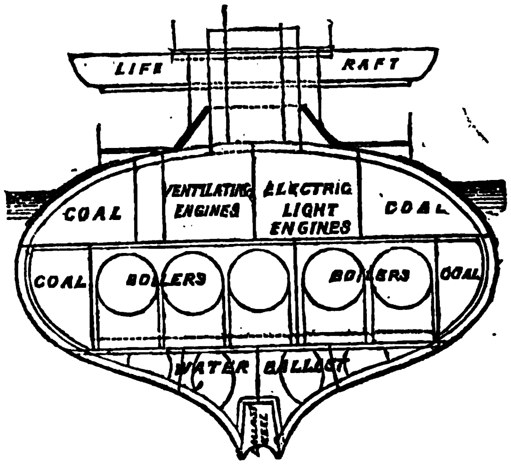
We give carefully reduced copies of diagrams taken from the engines when indicating 5668 horse-power collectively.

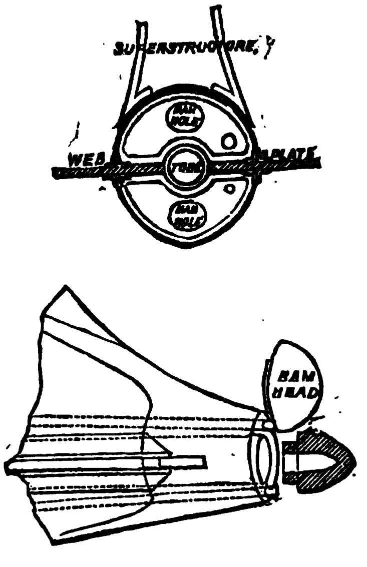
THE "POLYPHEMUS."

In our issue of July last we gave a description of the launch of the *Polyphemus* at Chatham; in the present number we give further particulars with engravings. The principal dimensions of the vessel are:—Length, 240 ft.; extreme breadth, 40 ft.; draught of water, 19 ft. 6 in. forward and 20 ft. 6 in. aft; and displacement 2,640 tons. The upper deck, or turtle-back deck as it is called, is 4 ft. above the water line along its middle; but the form of the vessel is such that it curves down and enters the water at an angle of about 45 deg., so that according to the usual acceptation of the term the ship has no free-board whatever. A light superstructure forecastle is raised to a height of 4 ft. 6 in. above the turtle-back to keep the bow up when the vessel is steaming at full speed, and upon this anchors and other fittings are placed. There is also a low superstructure aft to form a platform to walk upon and to give finish to the vessel. Between these two superstructures a wash strake is fitted so as to give a good sight line and to carry hand rails.

The water will sweep across the upper deck even in moderate weather; no attempt is made to keep it from doing so, but as in all the low-sided war vessels in the British Navy the principal hatchways are trunked up to a flying deck from which alone the interior of the vessel will be accessible at sea. The flying deck is 10 ft. 6 in. above the upper deck, and therefore 14 ft. 6 in. above the water, and it extends between the forecastle and the platform deck aft. There is only a handrail around the flying deck, bu three of the four hatchways which are trunked up open into circular deck-houses fitted with covers or hoods 6 ft. or 7 ft. above the deck; the fourth trunk contains the funnel with its casing and air spaces which also extend several feet above the deck, and may be closed in when required. The foremost trunked hatchway is divided into three by partition bulkheads, one, by far the largest of the three ways, leading to the forward part of the ship including the torpedo-rooms and magazines, and the two smaller ones leading to each of the two forward stokeholds. The deck-house over this trunk will form the forward pilot tower, and will contain the steering wheel and the various implements for working and fighting the ship. The middle deck-house stands over a trunked way which is also divided into three by partition bulkheads; two of these lead down to the aftermost stokeholds and the third to the foremost engine-room.



Midship Section.



The Ram Head, showing how constructed, carried and secured.

The aftermost trunk is divided into two, one passage leading down to the after part of the ship, and the other to the after engine-room. The deck-house over this trunk forms the after pilot tower, and will be similarly fitted to the forward pilot tower. The central deck-house may also be used as a pilot tower, but it will have no armour. The six Nordenfelt guns will be mounted in separate

SECTIONAL ELEVATION AND PLANS OF THE MAIN AND LOWER DECK.

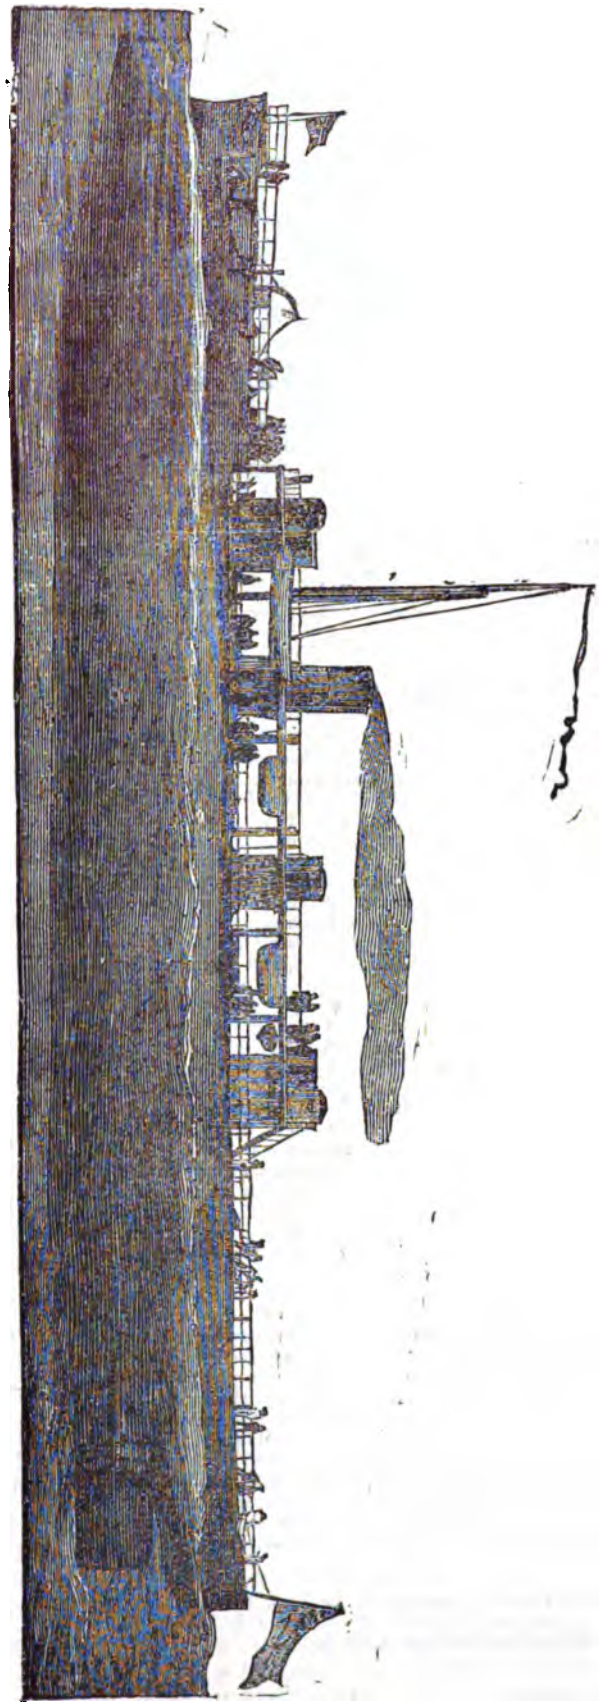
revolving turrets carried upon projecting framework at the level of the flying deck. There will be three of these on each side, one at the fore end of the flying deck, one at the middle, and the third at the after end.

The ship will carry four boats, two by davits from the flying deck ready for use, and two others kept lashed up under the flying deck aft. She will also be fitted with two life-rafts and gear for launching them in any weather.

Over the side of the turtle-back deck, to a depth of from 4 ft. to 6 ft., there are 3 in. of steel armour made up as follows:—Two ½ in. thicknesses of Landore-Siemens steel, one of which may be regarded as the skin of the ship; upon these is a 1 in. thickness of Whitworth fluid-compressed steel, which will stand a strain of 45 tons per inch, and upon this again there is a 1 in. thickness of hard Whitworth steel, also fluid-compressed, worked in plates 10 in. square, which are tested to a strain of 68 tons. The two outer thicknesses of the side plating were supplied by Sir Joseph Whitworth in compound plates already bolted together and worked to shape, and only requiring to be fastened on the ship. The plates forming the under inch thickness are all 10 ft. long and 2 ft. 6 in wide, so that each required thirty-six 10 in. squares or scales, as they are called, to cover it. The scales are secured with coned steel screw bolts, one at the centre of each of the plates, and one at each of the corners, so as to hold each of the four adjacent plates. Along the middle of the turtle-back deck the 10 in. scales are not fitted, so that here the armour is only 2 in. thick. The bases of the trunks from the hatchways to the flying deck are protected by a glacis of 6 in. steel-faced armour to a height of 3 ft. 6 in. above the deck; and the entire front of the foremost trunk is protected by 8 in. steel-faced armour, which also extends to a height of about 5 ft. above the flying deck, and gives protection to the pilot-tower.

Those who are at all accustomed to considering the requirements of a vessel of this character will not be surprised to observe from the diagrams how completely filled the ship is with necessary fittings and stores, and how very little space is left for providing even requisite accommodation, to say nothing of ordinary comforts, for the officers and men. Excepting the low superstructure forecastle there is no space above water available either for the stowage of stores or for accommodation, and this in a ship of 2,640 tons, and with engines of 5,500 indicated horse power, and having an available depth of hold of about 15 ft.; whereas in an ordinary ship of this displacement and power, space for nearly the whole of the accommodation and much of the storage would be found above the boundary at which the hull of the *Polyphemus* ceases. The 103 men who form the crew may manage to live in the limited spaces allotted them forward on the main deck, but they will barely be comfortable, notwithstanding the elaborate ventilators both for conveying in fresh air and for removing foul air which pass along overhead and considerably limit the area over which it is possible to stand upright. The officers also will fare but little better in their quarters on the main deck aft; their accommodation is not luxurious. The round turtle-back form of the upper deck indicated on the midship section is preserved forward and aft; indeed it is sharper towards the extremities, so that out towards the sides of the living deck both forward and aft it will be impossible to stand upright.

The whole of the central portion of the vessel over about one-third of the length is taken up by engines, boilers, and coal. The boilers are placed low down in the ship below the main deck; they are arranged in four water-tight compartments, three in each of those on the starboard side, and two in each of those on the port. Over



THE POLYPHEMUS.

them on the main deck are placed the ventilating fans, electric light engines, and various other small engines. There are two separate engine-rooms, one before the other, the forward set of engines working the port screw and the after set the starboard crew. The coal (250 tons) is carried in sixteen bunkers. The only communication below the upper deck between the compartments before the boilers, and those abaft the engines is along a passage on the main deck, which is walled in with plating on either side and top and bottom, so as to form a water-tight tunnel. The various boiler and engine-room compartments are accessible through water-tight doors leading from this passage, as well as from above, as already described. The vessel has two collision bulkheads to keep back the water in case her strongly framed bow should be strained in ramming. The chase torpedo tube extends from the ram to 2 ft. or 3 ft. abaft the inner of these collision bulkheads, and opens on the lower deck. Here the loading of this tube will be effected. Proceeding aft on the lower deck the next compartment is allotted to torpedo magazines. Abaft this again is the main torpedo chamber, where there are four tubes, two on each side. Independent air-compressing machinery will be carried in each of the torpedo chambers; each of which chambers will also carry a number of torpedoes ready for use; the main store of torpedoes will, however, be carried in the hold under the floor of the main torpedo chamber. The main magazines for the Snider and Nordenfelt ammunition are in the after hold, but it is also intended to fit a small magazine for Nordenfelt ammunition forward. Besides the keel ballast, which may be cast loose at pleasure, a considerable weight of water ballast will usually be carried in the inner bottom compartments under the boiler and engine rooms.

Whether the *Polyphemus* will be able to crush in the side of her enemy with her long pointed ram without her bow tube being so injured as to make it unfit for use, is doubted by most persons competent to give an opinion on the subject. The bow, however, is very strong, and great care has been taken to give the tube every chance of escaping uninjured. The tube proper is placed within an outer tube of great strength, against which, however, it does not rest except at its extremities; the outer tube being rigidly attached to and forming part of the framing of the bow. By continuing the armour down and attaching it to deep web plates which extend into the outer tube and out to 18 inches beyond the skin of the ship, an arrangement of great strength has doubtless been made. The front of the tube is a massive forging which is continued aft, above and below the tube, and is well able to take care of itself. The ram-head also is of fluid-compressed steel, and is almost solid; when in place it extends into the tube several inches, so that against all blows from the front it is firmly held by the forging just referred to. The ram-head is worked from inside the ship by a steel rod to which it is fixed, and when in place it is also held by a rod below.

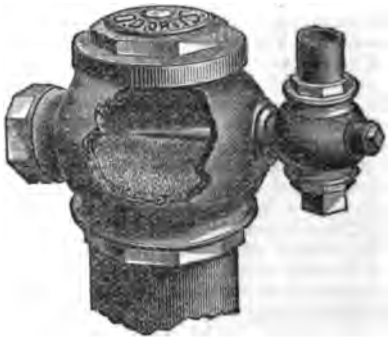
Two auxiliary balanced rudders are fitted forward, one on each side of the bow torpedo tube. They are carried upon strong vertical shafts by which they are worked, and when not required are drawn up into trunks within the hull. When in use these rudders may if desired be coupled up with the engine working the stern rudder, and all three rudders worked together.

It is confidently anticipated that a speed of 17 knots will be attained at the measured mile, but it can scarcely be hoped that the vessel will be able to sustain this speed for many consecutive hours. The distance she will be able to cover at her six hours' trial of continuous steaming will really be the measure of her capabilities in this direction. A consideration of vital importance in this vessel is her manœuvring power. Her only modes of attack being the torpedo and the ram, she must necessarily constantly endeavour to come to close quarters with the enemy, or to keep out of range of his guns. With a speed of 17 knots she will be able to elect whether she will fight or not with almost any ship at present afloat, and supposing she chooses to fight, the chance of her success will depend almost entirely on the rapidity with which she will be able to close in with the enemy, and having closed in with him, to manœuvre around him, so as to bring her torpedo tubes successively into the line of fire and within range, and also to use her ram. The vessel will doubtless possess the power of turning rapidly; the powerful rudders at both ends of the ship, and the cutting away of the fore foot and the after "deadwood" or heel will insure this, but the question of the degree of handiness can only be settled satisfactorily by actual trials.

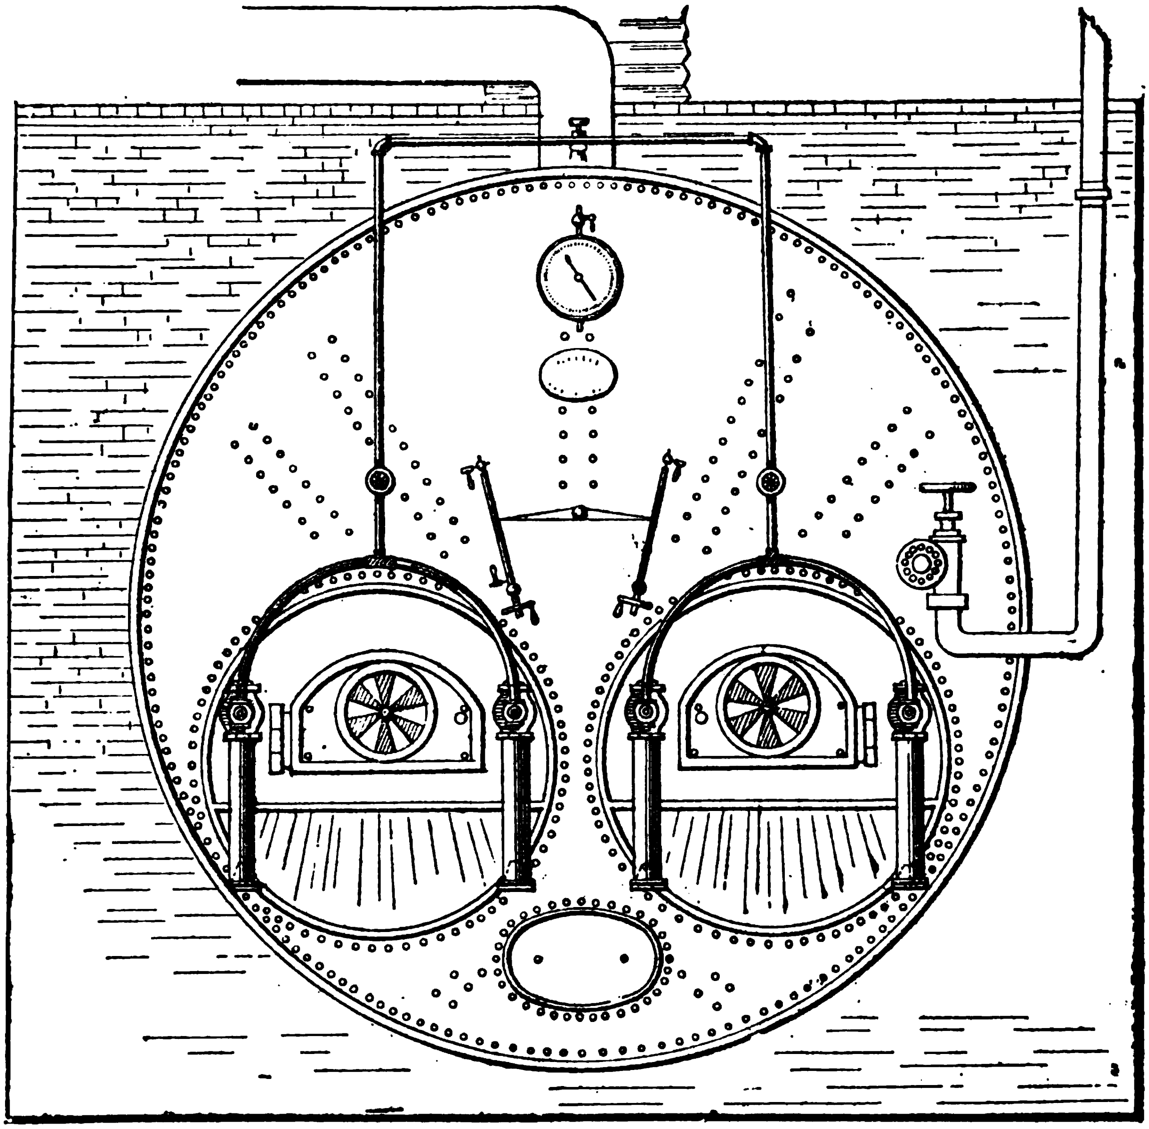
THE keel of a large steamer to be built to the order of a French firm, has been laid down at the iron shipbuilding yard of Messrs. Hodgson and Soulsby, at Blyth.

THE ORVIS SMOKE-CONSUMING AND FUEL-SAVING APPARATUS.

WE recently attended a practical demonstration of this important invention, which bids fair to eclipse all that has been previously attempted in the way of consumption of smoke, combined with economy of fuel. Mr. Orvis' improvements, though practically tested in the United States some year or so since with very satisfactory results, and are largely worked there, have but very recently been introduced on *this* side of the Atlantic; and we have refrained from giving a description of the invention until applied and thoroughly tested here, as there is a difference between English and American boilers, and steam-users might fairly argue that the success of the invention in America was no criterion of its prospects here. The invention has recently been applied to a boiler at the works of Mr. Fredk. Sage, Gray's Inn Road, London, W.C. Our illustration shews the boiler to which the consumer has been applied, and of which the following is an outlined description. The pith of the invention consists in Mr. Orvis having devised a method of supplying the furnace *with just enough oxygen of the air and hydrogen of steam to unite with the volatile hydrocarbons and other products of combustion arising from bituminous coal, and so as to form a mixture of carburetted hydrogen and olefiant gas, which readily ignites at a temperature of about* 800°, *and burns with a bright clear flame, creating perfect combustion.*



Mr. Orvis takes dry steam from the boiler, and conducts it through a small pipe down and across the furnace-front, over the fire-doors, as shewn, and branching off into two fine steam jets in front of each fire-door, which serve to draw the air up through pipes of larger diameter—open at the lower end—into an air chamber in a brass globe, at the top of each of the four large pipes or cylinders, and, a vacuum being created, the commingled air and steam is forced through other pipes into the furnace, and over the surface of the fuel, on a line converging towards the centre of the furnace. The



THE ORVIS SMOKE-CONSUMING AND FUEL-SAVING APPARATUS.

accompanying woodcut illustrates one of the brass globes used for injecting the oxyhydrogen current into the furnace. A portion of the globe is represented as being broken away, in order to shew the position of the steam-jet in the air-chamber. The commingled air and steam is distributed over the surface of the fuel, producing what the inventor terms his *surface draft*, and a valve is used to regulate the pressure, or to cut the steam off at will.

Mr. Orvis says, very reasonably, that he does not claim to be the first to introduce steam and air into a furnace to aid combustion, but he *does* claim to have discovered the correct combination of all the gaseous and æriform substances used; to use less steam than any who have preceded him, and to obtain, by his new and peculiar manner of applying the same, more perfect combustion and better results than have ever been attained before.

Mr. Orvis' invention was applied on the 2nd ult. to Mr. Sage's boiler; and, though so short a time has elapsed since it was affixed, we understand that a substantial saving in the cost of fuel is already apparent while the *smoke-burning* capabilities of the invention are apparent to any one who will visit Mr. Sage's premises, as, on the "burner" being started, the smoke is positively "killed," the chimney being absolutely smokeless.

Another great advantage attending the adoption of this apparatus is that whereas, in Mr. Sage's case, he had previously, owing to defective furnace arrangements, been obliged to burn expensive steam coal, at a cost of 16s. per ton, he informs us that he can *now* burn the commonest slack, at a cost of only 10s. per ton; and as the boiler in question requires about three tons of fuel per day, this would shew a saving of something like 18s. per day with the working of this one boiler. The invention has been widely adopted in the United States for *marine* boilers, and doubtless ere long it will find a similar application in this country. We shall watch its progress in that direction with considerable interest, and hope to refer to it again in these pages. We shall look forward also to seeing Mr. Orvis' invention included doubtless amongst the exhibits at the exhibition to be held at South Kensington, October 24th to November 26th, of the various appliances for preventing smoke, and obtaining heat with the least possible noxious products.

SUFFIELD'S PATENT FRESH WATER DISTILLING APPARATUS.

We have recently inspected a novel and very efficient arrangement of fresh water distilling apparatus, invented by Mr. G. Rayner, of the firm of Messrs. Suffield, Railway Copper Works, James-street and Devonport-street, Commercial-road, East, London, E., and of which the firm named are the sole proprietors and manufacturers. The apparatus is volutical in its internal circulating construction; and, from its extreme simplicity, compactness, and portability, it is particularly adapted for use on board ship. The mode adopted for fixing the internal parts is such as to render it practically impossible for the fresh water and salt water to become mixed. The ***rapidity*** with which the distillation is effected in this apparatus and the fact of the resultant water being ***absolutely fresh***, augur well for its coming largely into use for the Marine Service; and we purpose, in our next issue, giving illustrations and results of the working trials of this speciality just being introduced by Messrs. Suffield.

LUMINOUS PAINT.

This useful invention, which is due to the late Mr. W. H. Balmain, a chemist, well known as the originator of several important chemical processes, and founder of the Greenbank Alkali Works, St. Helen's, Lancashire, cannot be brought too prominently under the notice of shipowners, as its application for marine uses is one of the points of the greatest value in its favour. The inventor, after many years of study and experimenting, succeeded in producing a substance which would practically serve the purpose of a light for dark places; for though there is no novelty in the production of a mere phosphorescent compound, to keep luminous for a very brief period only, it is to the late Mr. Balmain that the credit is due of producing a really useful light-holding powder, to be made up and used as a paint, which takes up or *stores* the daylight to which it is exposed, and emits the same in the dark: for instance, if a board or piece of sheet iron be covered with this luminous paint, and exposed to ordinary, diffused daylight or strong artificial light, it will, when taken into any dark place, say the hold of a ship, give sufficient light to enable objects to be distinguished.

At the time of Mr. Balmain's death he had not then completed the experiments he was conducting, and they were taken up and concluded by Messrs. Ihlee & Horne, of 31, Aldermanbury, London, E.C., who have succeeded in getting the invention applied practically for various uses, and on a large scale, especially considering that it has been comparatively so recently introduced. Availing ourselves of an invitation received from the firm named, we attended at their offices a short time since to satisfy ourselves of some of the uses to which this "*bottled daylight*" (as it has been termed by a contemporary) may be put. The room used for demonstrating the application of the invention was made perfectly dark, all daylight being carefully excluded; the ceiling, however, had been painted with three coats of the luminous paint, and we were surprised to find the amount of light which this must have collected and stored up, as the light emanating from the ceiling was sufficient to render plainly discernible the various objects in the room; amongst others a life buoy, a clock dial, shewing the hands and figures very distinctly, and a variety of labels and notices, such as "Mind the hatchway," and so on. Another demonstration of a different nature interested us particularly: into a room—from which all light also had been excluded, but not painted with anything but the ordinary paint, and the ceiling whitewashed—was brought a large square of glass, the back of which had received several coats of luminous paint, and which rendered the room light enough to discern the various objects in it. To utilize and adapt this latter application on board ships, and especially in ***dangerous*** as well as ***dark*** places, such as powder magazines, lamp and spirit rooms, &c., portable boards or sheets of thin metal, or glass painted with the luminous composition, act as lanterns; as, after being taken into the daylight and exposed for a few minutes to the light, they may be carried into the dark places to which access is desired. Again, at night-time these portable painted boards or lanterns may be taken to a safe place, and charged with artificial light, by holding before a ship's lantern, and then be carried, charged with luminosity, into the dark or dangerous places.

For marine uses we consider the invention of the utmost value, and we are pleased to find that this view is taken also by our Admiralty, who have, together with other public and administrative bodies, interested in naval matters, adopted the luminous paint. We understand from Messrs. Ihlee & Horne that one of the most recently received orders is one for 600 ft. of their paint to be placed on the stern of H.M.S. *Lord Warden*. We are pleased to find also that the Southampton Harbour Board have recently passed a resolution that all their life-buoys on the quay are to be painted in future with it, and that the Trinity House have ordered channel and river-buoys to be similarly painted for Harwich and the Thames. We note also that the steam fire-engine float, *Beaver*, lying off Cherry Garden Pier, below London Bridge, is to have a band of luminous paint 18 in. wide all round bulwarks.

Though we have confined ourselves to the *marine* applications of Mr. Balmain's invention, we need scarcely add that it is of course adapted for an infinite variety of applications on land, and we are glad to find it is largely and deservedly adopted.

SANITARY PAINTS.

THE attention of sanitarians, shipowners, and others having, during the last few years, been directed to the encouragement of practical improvements upon the old and highly noxious white lead, and the many other injurious pigments used in painting and decorating, has resulted in the introduction of numerous preparations with this object in view:—the *latest*, however, is one which is especially deserving of notice in these pages.

Messrs. Griffiths, Berdoe & Co., of 51, South John Street, Liverpool, and 34, Leadenhall Street, London, E.C., the proprietors of the Sanitary Paints, have for many years devoted themselves to the improvement of the ingredients of ordinary paints, and have established for themselves a deservedly wide spread reputation in this respect. The manufacturing premises of the Company in Eaton Street, Liverpool, are on a very large scale and additions thereto, will, we understand, shortly become necessary: the premises are fitted with all the newest and most approved descriptions of chemical and mechanical appliances; a notable feature in connection with the works being the chimney shaft, which has a height of 325 ft. and is 36 ft. diameter at the base.

The productions of the Sanitary Paint Company are both numerous and various. We only specialize here, however, those which come within our province to notice as regards *Marine* applications, viz., "Griffiths' Patent White." In addition to this taking at the Paris Exhibition of 1868 the highest distinction conferred upon paints, it gained in the same year the special Richardsonian Medal of the Sanitary Institute of Great Britain; the Duke of Northumberland, the president, remarking at the time that he might with justice designate this innocuous substitute for white lead, as "the greatest discovery ever made for preventing the dreadful suffering caused by the use of lead paints." It is not for us to detail the further honours which have been bestowed upon Messrs. Griffiths' discoveries and their productions, but we come now to the practical features of the same as regards the painting of ships especially. We take as our authority Dr. Bartlett, one of our most eminent analysts who, in a Paper read by him on Griffiths' White Paint, at the Social Science Congress at Cheltenham, stated that he was earnestly desirous to see it very shortly in general use, inasmuch as he was assured that it "never causes illness to those engaged in its manufacture, that those who may be called upon to *use* it, will never be subjected to those diseases which are so deleterious to painters; that the pigments mixed with it do not produce any ill effects when freshly applied, and furthermore, that they do not lose their colour." The same authority in speaking of some experiments he made with this paint, remarks, that ordinary paints permit rust to accumulate beneath them, and therefore *scale off*, but *this* paint forms a *chemical combination with the iron*, and rust does not occur under it, therefore it does not scale off. Dr. Bartlett proceeds, "Griffiths' White when employed to paint iron vessels, is reported to stand salt water in a highly satisfactory manner, the iron being found to be unaffected by rust. This compound also resists the heat of boilers, and those who have used it affirm that the iron is always protected by it, which is by no means the case when red lead paint is used." Such evidence as the preceding forms a strong recommendation in its favour for marine uses and the more especially also, as we are informed by the proprietors that the body or covering power of this paint is about double that of white lead, and its cost is of course proportionately less.

The "Enamel Paint" is a non-poisonous preparation in all varieties of colour, which may be used to dry either with a gloss without the necessity for any varnish or with a dead surface, where a gloss may be *un*desirable. It is non-porous, and therefore damp proof, we understand also, that it successfully withstands the effects of steam, and arrests oxidation which should render it well adapted for marine uses.

The other specialities of Messrs. Griffiths, Berdoe & Co., to which we have pleasure in drawing attention here, are "Marine paint," for use in the inside and outside of ships, and all submerged metal and wood work, "Brockley Black," ready for use, and more particularly adapted for boilers, engines, and all work exposed to heat, "Anti-Fouling Paint" which contains no mercury to affect the iron, but which is very powerful in protecting iron and wood ships from corrosion and decay, and preventing *fouling*. Lastly, there is a special preparation termed "Funnel Paint" well adapted for the purpose indicated by its name, as it will not, we understand, blister or scale off.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of the* MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Belle of Devon.—On June 25th there was launched from the shipbuilding-yard of Mr. W. H. Shilston, Coxside, a schooner of about 100 tons register. She was christened by Miss C. Shilston (daughter of the owner) the *Belle of Devon*. The vessel is intended for the Newfoundland trade, and will be under the command of Captain J. Quiller.

Queensferry.—On June 25th there was launched from the shipbuilding yard of Messrs. Robert Thompson & Sons, Southwick, Sunderland, an iron screw steamer, built to the order of the Beta Steamship Company (Limited), Sunderland, of the following dimensions, viz.:—Length, 225 ft.; breadth, 32½ ft.; depth, 16 ft. She has been constructed under Lloyd's special survey to class 90 A 1. The engines, which are of 120 n. h. p. are by Messrs. Black, Hawthorn, & Co., Gateshead. The vessel has two decks of iron, long half poop, and bridge decks, also of iron, topgallant forecastle of wood, and chart-house and companions of iron, and will be fitted with all the latest improvements. The cabin is fitted up aft for the accommodation of captain and officers, the bridge-house amidships for engineers and petty officers, and the forecastle for seamen. She has three steam winches and donkey boiler by Messrs. Welford and Wigham, Pallion, patent midship steering apparatus, and aft screw gear by Messrs. Crawford & Sons, Monkwearmouth; Emerson, Walker, & Co.'s patent windlass, &c., &c. As the vessel left the ways she was christened the *Queensferry* by Miss Rogerson, of Croxdale Hall.

Uppingham.—On June 27th there was launched from the ship yard of Messrs. Raylton Dixon & Co., of Middlesbrough, steamer named the *Uppingham*, built to the order of Messrs. Galbraith, Pembroke & Co., of Austin Friars, London. Her dimensions are :—300 ft. over all, 38 ft. breadth, and 26 ft. 2 in. depth of hold. Her gross tonnage will be about 2,220 tons. She is built on the spar-decked rule, has a main deck of iron, and spar-deck of teak, and has water ballast throughout on the cellular principle. She will be fitted with engines of 200-horse power, nominal, by Messrs. Thomas Richardson & Sons, of Hartlepool, and completed with all the most recent appliances for vessels of the highest class. On leaving the ways she was christened the *Uppingham* by Miss Page, daughter of Captain Page, of London.

Equity.—On June 27th there was launched from the shipbuilding yard of Messrs. D. Baxter & Co., North Sands Point, Sunderland, an iron screw steamer of the following dimensions :—Length, 130 ft.; breadth, 20 ft.; depth of hold, 10 ft. She is of somewhat novel construction, being specially designed for carrying 350 tons deadweight cargo on a mean draught of 2 ft. 10 in. She is classed 100 A 1 at Lloyds, having been built under special survey. The ceremony of naming the vessel was performed by Mrs. Williams. The *Equity* is built to the order of Messrs. Jenkins & Co., of Swansea, and is intended for the Welsh iron ore trade.

Broomhaugh.—On June 27th, was launched an iron screw steamer, built for Messrs. Elliott, Lowrey, and Dunford, Newcastle, by Messrs. C. S. Swan & Hunter, Wallsend, and of the following dimensions :—Length between perpendiculars, 285 ft.; breadth, 36 ft. 3 in.; depth of hold, 24 ft. 6 in.: tonnage, gross, 2,120 tons; nett, 1380 tons. The vessel was named the *Broomhaugh*, by Miss Ethel Lowrey. After the launch the vessel was towed to St. Peters to receive her machinery of 200-horse power, which has been made by Messrs. R. & W. Hawthorn.

Boyne.—On June 29th, Messrs. Wm. Gray & Co. launched from their yard, at West Hartlepool, an iron screw steamer of the following dimensions :—Length, 285 ft. between perpendiculars; breadth, 35ft. 3 in.; depth, 24 ft. 6 in.; class, 100 A 1 at Lloyd's. The vessel is built on the three deck principle to the order of the Mercantile Steam Shipping Company, London, and is intended to carry 2,800 tons dead weight. She is fitted with every recent improvement, including steam steering-gear by Messrs. Halliday, of Sunderland, and patent windlass by Messrs. Emerson & Walker, of London. Her engines are to be fitted by Messrs. Thomas Richardson & Son, of Hartlepool. On leaving the ways the vessel received the name of *Boyne*, and the christening ceremony was performed by Miss Harriet Smith, of Stockton.

Galatia.—On June 29th, Messrs. David and William Henderson & Co. launched from their shipbuilding yard at Meadowside, an iron screw steamer built to the order of the Barrow Steamship Company, of the following dimensions :—Length, 240 ft.; breadth, 37·6; depth, 29·6, with a gross tonnage of 3,150 tons. She will be supplied by the builders with compound engines of 500-horse power. As the vessel left the ways she was named the *Galatia* by Miss Meiklereid, daughter of Captain Meiklereid. The *Galatia* will be fitted with all the latest and most approved appliances, and when completed will form one of the Anchor Line Fleet.

Manna.—On July 11th, Messrs. William Gray & Co. launched from their yard at West Hartlepool, an iron screw steamer of the following dimensions :—Length between perpendiculars, 216 ft.; breadth of beam, 31 ft.; depth of hold, 15 ft. 2 in. Class, 100 A at Lloyds. The vessel whose name is *Manna*, is built to the order of Mr. Henry Martini, of Glasgow, and is expected to carry 1,300 tons deadweight. She is fitted with every modern improvement, including steam steering gear by Messrs. Muir & Caldwell, of Glasgow, and patent steam windlass by Messrs. Napier Brothers, of Glasgow. The engines are to be fitted by Messrs. Blair & Co. (Limited), Stockton.

Hesper.—On July 12th Messrs. Edward Withy & Co., launched from Middleton Shipyard, West Hartlepool, an iron screw steamer of the following dimensions :—Length, b.p., 257 ft. 6 in.; beam extreme, 34 ft. 6 in.; depth moulded, 20 ft. 4½ inches; and dead weight carrying capacity, 2,400 tons. She is built to Lloyd's highest class, and has long quarter deck, bridge-house, and top-gallant forecastle; double bottom all fore and aft, on the cellular principle; four hatches arranged to meet the Board of Trade regulations as feeders for grain cargoes; four steam winches, patent windlass, and all modern improvements. Her decks, chart-house, engine, and cabin skylights, and companions are of iron, and she will be rigged as a topsail schooner. The engines will be supplied by Messrs. Blair & Co., of Stockton-on-Tees. This vessel is No. 99 in the builder's yard, and is the sixth launched by her builders this year. As she left the ways she was christened *Hesper* by the Mayoress of Hartlepool, Mrs. J. Horsley.

Andora.—On July 12th an iron sailing ship was launched from the building-yard of Messrs. Richardson, Duck & Co., South Stockton, of the following dimensions, viz. :—Length over all, 264 ft.; length between perpendiculars, 244 ft.; breadth, extreme, 39 ft.; depth in hold, 24 ft. 3 in.; tonnage, gross, about 1,724 tons; tonnage, nett, about 1,667 tons. She is classed 100 A 1 at Lloyd's, and has been built under special survey. The vessel has a full poop for the accommodation of first-class passengers and Captain and Officers, a top-gallant forecastle for Crew, and a deck-house amidships for the Petty Officers; galley, &c. The ship has been built for Messrs. E. F. & W. Roberts, Liverpool. As the vessel was leaving the ways she was christened the *Andora* by Mrs. Mathias, wife of Captain Mathias, of the Owner's firm.

Brocadalie.—On June 28th there was launched from the building-yard at Jarrow a screw steamer, built to the order of Messrs. Temperley & Co., of Newcastle. She is 303 ft. long, 37 ft. broad, and 36 ft. deep. She has Emerson, Walker & Co.'s patent windlass, and will be classed 100 A 1 at Lloyd's, and is named the *Brocadalie*.

Lesseps.—On July 13th there was launched from the shipyard of Messrs Raylton, Dixon & Co., Middlesbrough, the iron screw steamer *Lesseps*, built to the order of Norwegian owners. Her dimensions are :—270 ft. long by 34 ft. 9 in. breadth of beam, and 24 ft. 3 in. depth of hold. Her gross tonnage will be about 1,825, and she will carry about 2,500 tons deadweight on 22 ft. draught. She is built on the three-decked rule, having main and upper decks laid, the latter being of iron. She has water ballast in the after hold, and in a large chamber in the main hold forward of the engine-room. She will be fitted with engines of 150 horse-power by Messrs. Blair & Co., of Stockton, and completed with all the most recent appliances for vessels of this class. On leaving the ways she was christened the *Lesseps* by Mrs. Belk, of Middlesbrough.

Llangollen.—On July 13th a screw steamer of about 2,400 tons burthen was launched at Wallsend from the yard of Messrs. Schlesinger, Davis, & Co. This vessel, named the *Llangollen*, has been built to the order of Mr. Charles E. Stallybrass, of Cardiff, and classes 20 years in the Liverpool Underwriters' Registry. Her measurements are :—260 ft. between perpendiculars, 36 ft. beam, and 19 ft. depth of hold. Powerful steam winches are placed at each of the principal hatchways for loading and discharging cargo. Harfield's steam windlass is fitted; water ballast, and every other necessary requirement for speedy moving and working of the vessel have been provided. The cabins for the captain, and a few spare berths are under the full poop aft, and the engineers' accommodation is under the fore part of the bridge. Engines of 160 nominal horse-power will be supplied by Messrs. Black, Hawthorn & Co., Gateshead. The engines are inverted direct-acting compound surface-condensing, and have cylinders 36 in. and 68 in. diameter, and 36 stroke; 80 lbs. working pressure of boiler. As the vessel left the ways she was named by Miss Edith Gertrude Stallybrass.

Tempo.—On July 14th a screw steamer named the *Tempo* was launched from the yard of Messrs. T. & Wm. Smith, at North Shields. She is intended for the coasting coal trade and the Baltic, and has been built to the order of Messrs. Fenwick & Reay, of London. She is 230 ft. long, by 35 ft., and in depth 17 ft. Her engines are built by Messrs. Hawks, Crawshaw, & Son, Gateshead, and are of 140-horse power. She is schooner-rigged and fitted up with Donkin & Nichol's steering apparatus, and with water ballast arrangements. She will be commanded by Captain Craig.

Thalatta.—On July 13th, there was launched from the shipbuilding and engineering works of Messrs. W. H. Potter & Son, Queen's Dock, Liverpool, an iron sailing ship of the following dimensions :—Length, 280 ft.; beam, 39 ft.; depth in hold, 24 ft.; tonnage, b.m., 2,000 tons, and ditto register, 1,800 tons. The vessel was christened the *Thalatta*, by Mrs. M. M'Diarmid. The *Thalatta* has been built for Messrs. M'Diarmid and Greenshields, of Liverpool. She will class 100 A at Lloyd's and 20 years in Red in the Liverpool Underwriters' books, but her scantling is considerably in excess of the requirements of both books.

Portugal.—On July 16th, Earle's Shipbuilding and Engineering Company (Limited), Hull, launched a steamer for Portuguese Owners. The vessel was named the *Portugal* by Mrs. Bromage, of London. The *Portugal*, which is intended to convey the mails and passengers between Lisbon and the Portuguese settlements on the West Coast of Africa, has been built for the Empress Nacional of Lisbon. She is a spar-decked ship of about 2,000 tons gross register, built to class 100 A 1 Lloyd's, and is 290 ft. long between perpendiculars, 35 ft. beam, and 25 ft. 6 in. deep.

She is brig-rigged, and has accommodation in the 'tween decks aft for 60 first-class passengers, and amidships for 30 second-class. There is also accommodation in the 'tween decks for third-class passengers. Arrangements are made for carrying 400 tons of water ballast. She will be propelled by a compound surface-condensing engine of 220 nominal horse-power, having cylinders 40 in. and 72 in. diameter and 45 in. stroke, and supplied with steam of 80 lbs. pressure from two large single-ended boilers, placed with their backs to the engines. On the spar-deck is a large donkey boiler, which supplies steam to powerful winches and cranes.

Palm Branch.—On July 16th there was launched the first of two steamers being built by Messrs. Bartram, Haswell & Co., South Dock, Sunderland, to the order of the Nautilus Steam Shipping Company, of whom Messrs. F. and W. Ritson are directors and managers. The dimensions of the new vessel are as follows:—Length between perpendiculars, 260 ft.; breadth, extreme, 36 ft.; depth to the top of floor, 18 ft. 6 in. She is classed 100 A 1 at Lloyd's. Her dead weight carrying capacity is 2,200 tons. She is constructed with iron decks, except full poop, four large steam winches with boiler of extra large size, to work to 80 lb. pressure, and is specially designed and fitted to carry grain cargoes in bulk. Her engines are supplied by Messrs. Dickinson, of Monkwearmouth. She has two boilers multitubular form, each 13 ft. mean diameter and 10 ft. 6 in. in length, heating surface 3,200 sq. ft., and working pressure 80 lbs. As the vessel left the ways the christening was performed by Miss Bella Ritson, who named her the *Palm Branch.*

Navarre.—On July 16th the Barrow Shipbuilding Company launched from their yard a steamer named *Navarre*, built for the Société Générale Transport Maritime, Marseilles. The vessel is 4,000 tons burthen, being 400 ft. long, 40 ft. broad, and 32 ft. 6 in. depth of hold, with 2,500 indicated horse-power. She is intended, along with a sister boat building in the same yard, to trade between Marseilles and the Brazils.

Ashdene.—On July 16th Messrs. Osbourne, Graham & Co., of Hylton, launched from their shipbuilding yard an iron screw steamer, to the order of Messrs. Bulman & Dixon, of Sunderland, of the following dimensions, &c.:—Length, 230 ft. by 33 ft. beam, and 16 ft. 3 in. deep, with raised quarter deck, bridge-house, and topgallant forecastle, and with compound engines by Mr. George Clarke, with cylinders 28 in. and 53 in. by 36 in. stroke. She has been fitted with large hatches and three powerful steam winches, and all appliances for rapid loading and discharging, patent windlass, Davis' steering gear amidships and Hasties' aft. On leaving the ways she was named the *Ashdene* by Mrs. John Dixon.

Ross.—On June 28th, a vessel named the *Ross*, built at Howdon to the order of Messrs. John Cory & Son, of Cardiff, was launched. She is 240 ft. long, 33 ft. broad, and 18 ft. deep. She is fitted with patent brass cone windlass by Emerson Walker & Co., and has been built to take the highest class at Lloyd's, and is the 12th vessel built by Palmer & Co. for the same owners.

LAUNCHES.—Scotch.

Tower Hill.—On June 28th, at Dobie & Co.'s yard, Govan, a further addition to the Liverpool steam fleet was safely put into the water. The *Tower Hill* is a sister ship to the Notting Hill, which has excited some interest lately owing to her novel arrangements, and which has just sailed for Calcutta. Like her, the *Tower Hill* is of steel, and provided with two propellers at the stern instead of the usual single screw. Her dimensions are 420 ft. long by 45 ft. beam, with a carrying capacity of over 5,000 tons deadweight upon a light draught of water. Her engines and boilers are by Messrs. Jas. Howden & Co., Glasgow, and they are to indicate upwards of 3,000-h.p., and to propel the steamer between 13 and 14 knots loaded. The same builders have a third steamer, the *Ludgate Hill*, of still larger dimensions, rapidly approaching completion, also on account of Mr. W. H. Nott and Mr. W. Becket Hill, the owners of the new line.

Thistle.—On June 28th, Messrs. Blackwood and Gordon launched at Port Glasgow, a screw steam-yacht, called the *Thistle*, for the Duke of Hamilton. Its dimensions are:—Length over all, 203 ft.; length over tonnage, 180; breadth of beam, 25 ft.; depth of hold, 14 ft.; of 600 tons, and of the highest class at Lloyd's. The *Thistle* is schooner rigged with clipper stem and round stern. She is supplied with four boats and a steam launch, the windlass is driven by steam, and there are mounted on deck a couple of brass four-pounder guns. The builders supply a pair of compound inverted surface-condensing engines of the highest make and finish, capable of indicating no less than 600-horse power. Cylinders, 26 in. and 52 in., with a stroke of 2 ft. 9 in. It is expected that at least 14 knots will be got out of the new vessel. The boiler is 12 ft. in diameter and 14 ft. long, with four furnaces to be fired from both ends. Iron bunks run alongside the engines and below the cabin capable of holding 160 tons of coal. Mr. Cornelius Young, of Cowes, Isle of Wight, will command her. As the new yacht left the ways she was named by the lady of Mr. Auldjo Jamieson, Edinburgh, chamberlain to the Duke of Hamilton.

Ro omahana.—On June 28th Messrs. Russell & Co., Cartsdyke, launched a sailing ship of 1,624 tons, which has been built to the order of Mr. J. R. de Wolff, of Liverpool, for the East Indian trade, and is fitted with patent capstan windlass, Emerson Walker & Co.'s patent. Her dimensions are:—Length, 248 ft.; breadth, 38 ft.; depth, 22 ft. 9 in.

Austerlitz.—On June 29th there was launched from the building-yard of Messrs. Hall, Russell & Co., Aberdeen, an iron screw steamer named *Austerlitz*, of the following dimensions:—Length, 265 ft.; breadth, 35 ft. 6 in.; depth, 19 ft. 6 in., and 1,700 tons. This vessel has been built under special survey, taking the highest class in both Lloyd's and Liverpool Registrys, and will be fitted with compound surface condensing engines of 170-horse power nominal, water ballast, patent windlass and capstan, steam winches, steam steering gear, and all the most approved appliances for facilitating the loading and discharging of cargoes. She has been built to the order of Messrs. Allan C. Gow & Co., Glasgow, and is specially fitted for the China and Atlantic trades. As the vessel left the ways she was named *Austerlitz* by Mrs. Clements, and was afterwards towed to the sheer poles, for the purpose of receiving masts and machinery.

Liimfjorden.—On June 29th there was launched from the building-yard of Messrs. Lobnitz & Co., Renfrew, a screw steamer of the following dimensions:—165 ft. by 24 ft. by 17 ft. The vessel is built of steel, and classed in Verita's highest class, and will be fitted with the builders' compound engines of 85-horse power nominal. As she left the ways she was named *Liimifjorden* by Miss Annie Lobnitz. Immediately after the launch she was taken into the builders' tidal dock, where she will receive her boilers and machinery. The *Liimfjorden* has been built to the order of the United Steamship Company, of Copenhagen, for their Baltic trade. Captain Petersen is to command the vessel.

Spartan.—On July 12th the *Spartan* (s), built by Messrs. James & George Thompson, of Clyde-bank, for the Union Steamship Company, was launched. She is the 38th vessel which that company has built or purchased for their mail service with the South African Colonies since they commenced the service in 1857. The *Spartan* is the largest vessel which has yet been placed on the Cape of Good Hope service, her dimensions being:—Length between perpendiculars, 365 ft.; beam, 43 ft.; depth, 32·6 ft.; and her gross registered tonnage is estimated to be about 3,750. The ship is fitted with every modern appliance, and will carry 150 first-class passengers, 50 second, and 100 third. Her engines are 3,400 horse-power. She is fitted with 11 water-tight bulkheads, and is heated throughout by steam.

Claymore.—On July 14th Messrs. J. & G. Thomson launched from their yard at Clyde Bank a screw steamer built to the order of Mr. David M'Brayne, 119, Hope-street, as a consort to the *Clansman* and *Clydesdale*, so long known in the Stornoway trade. The ceremony of naming her the *Claymore* was performed by Miss Annie Thomson, of Mountblow. She has a complete awning deck similar to *Clansman* (s), her dimensions being:—Length, 225 ft.; beam, 29½ ft.; depth, 15 ft.; and from her fine lines is expected to sail very fast. She will be supplied with compound engines by her builders, and is fitted with every improvement for comfort of passengers and working of cargo.

Alaska.—On July 15th the *Alaska* was at last successfully launched from the shipbuilding yard of Messrs. Elder & Co., Fairfield. The *Alaska* was to have been launched on the previous Wednesday, and the vessel at first glided smoothly down the ways, after the ceremony of naming her had been performed. About halfway, however she stopped, and remained fast, and all efforts to get her into the water were unavailing. The *Alaska* has been built for the Guion line, and it is of large proportions. Her length is 520 ft., and she has five decks, on the fourth of which alone accommodation can be provided for 1000 passengers. Her tonnage is 8000, and her indicated horse-power 10,500. After being launched, the *Alaska* was taken to Messrs. Elder's private dock, where she will be fitted with engines, &c. She lies beside the Russian war-ship, *Peter the Great*, in comparison with which she is of huge dimensions.

Savona.—On June 28th Messrs. Steele & Co., Greenock, launched from their shipbuilding yard a steamer, built to the order of Messrs. James Currie & Co., of Leith, for the Leith, Hull, and Hamburg Steampacket Company. The vessel is constructed of steel, and is

250 ft. long, 33 ft. broad, and 17 ft. 3in. in depth, with compound surface-condensing engines of 120 horse power nominal. Her gross tonnage is 1084 tons. She is similar in every respect to the *Modena*, launched by Messrs. Steele & Co. for the same owners about six weeks ago.

Rosa Beilo.—On July 1, there was launched at Granton this steam yacht. She has been built by Messrs. D. Allan, builders, Granton, to the order of Messrs. Wm. Gunn & Co., Granton. She is 45 ft. in length, 8 ft. 6 in. in breadth, and her hold 5 ft. 10 in. in depth.

Ville de Naples.—On July 12th Messrs. A & J. Inglis launched from their shipbuilding-yard, at Pointhouse, a screw steamer, of 1.900 tons, for the Mediterranean mail and passenger service of the Compagnie Générale Transatlantique. This steamer is a sister ship of the *Ville de Rome*, built by the same firm. The principle dimensions are:—Length, 314 ft.; breadth, 34 ft. 3 in.; depth, 25 ft. 6 in. Immediately after the launch the vessel was berthed under the sheer-legs at the builder's wharf, where they at once commenced fitting the engines, of 2,400-horse power, on board. The ceremony of naming the vessel *Ville de Naples* was performing by M. Bocaudé.

TRIAL TRIPS.

White Sea (s).—On June 24th, the Dundee, Perth, and London Shipping Company's steamer, *White Sea*, built by Messrs. Alexander Stephens & Sons, went her trial trip. The steamer took her departure from the roads opposite Camperdown dock about 11 o'clock. There was a stiff breeze from the south-west, but the weather was bright and genial, and the sea smooth. After proceeding within sight of the Island of May and the Bass Rock, the vessel was put about for Dundee. In the course of the run the speed of the vessel was tested, and it was found that she steamed at the rate of 11½ knots. The engines worked very smoothly.

Puertoriqueno.—The new steamship *Puertoriqueno* built for the line of Spanish steamers managed by Messrs. White, Forman, & Co., of this city, intended for trading between Liverpool and Porto Rico, was taken out on her trial trip on June 29th. Amongst those on board were Messrs. Forman, Charwarri, of San Juan; Vidol, of Ponce; Casson & Edwards, of Manchester; Horn, Davidson, M'Kaig, and Glass, of Liverpool; W. Jones, of Seaforth, &c. The vessel left the Prince's Landing-stage a few minutes after ten a.m., and proceeded down the river under easy steam until she passed the bar, and then headed towards the Welsh coast, passing near Llandudno Bay, when she was again turned towards Liverpool, cruising about in various directions until seven o'clock in the evening, when she was put into the Wellington Dock In the course of the trip she proved herself to be a steady. and pleasant steamer, having only a very small degree of vibration. The *Puertoriqueno*, which is about 2200 tons gross measurement. is 280 ft. in length, by 35 ft. 8 in. in breadth, 24 ft. 7 in. in depth, is of iron, and was built by Messrs. R. & J. Evans, of, Liverpool. She is fitted with compound engines, with cylinders of 33 and 66 in. in diameter, with a stroke of 42 in., with one steel boiler, having six furnaces, and working at a pressure of 80lbs. to the square inch. She will carry 3,000 tons dead weight. Her engines which are of very fine construction, were made by Messrs. David Rollo & Sons, of this city. At 68 revolutions per minute, the vessel made eleven knots per hour. The *Puertoriqueno* has four steam winches, supplied by Messrs. Taylor & Co., and has steam steering gear, made on Harrison's principle, by the Patent Steering Engine Company. The ship and engines were designed by Mr. G. Goodwin, of this city, under whose superintendence the construction of the whole was carried out. The day's proceedings gave great satisfaction to all on board.

The Anjer Head.—On July 1st there arrived in Cardiff, on the completion of her trial trip from the Tees, the *Anger Head*, which has been completed by Messrs. Raylton Dixon & Co., of Middlesbrough, to the order of Messrs. Angier Brothers, of Bishopsgate-street, London, being the second vessel of her size which has been built for this firm by the above-named builders. She is a boat of 286 ft. over all, by 36 ft. beam, and 24 ft. 6 in. depth of hold, having a gross tonnage of 2,015 tons, and carrying capacity of 2,900 or 3,500 tons measurement. She is built in excess of Lloyd's highest class. Has iron main deck, and upper deck of pitch pine, water ballast in fore and main holds and under boilers. Her engines, which are by Messrs. Thomas Richardson & Sons, of Hartlepool, have given most satisfactory results, as the vessel made the run to Cardiff from the Tees in 62 hours, an average of nearly 12 knots per hour.

Peking.—On July 2nd, the *Peking*, a screw steamer, built by Messrs. Wigham Richardson & Co., for Messrs. Wm. Milburn & Co.'s China Line, started for its trial trip from the mouth of the Tyne. The *Peking* is similar to the *Cha Keiang*, *Yangtse*, *Amoy*, *Ningpo*, *China*, and other vessels of this line. It is 275 ft. from stem to stern, 33 ft. beam, and 23 ft. depth of hold. The engines, which are the builders' own make, are 200-horse power, indicating 700-horse power, and the speed obtained during the trip was over 13 knots. She is fitted with Emerson Walker's patent direct steam windlass, and is built to accommodate 36 first-class cabin passengers, and 400 Chinese between decks.

Corsican.—The new screw-steamer *Corsican*, built to the order of Messrs. C. & J. Macfarlane, Oswald-street, Glasgow, specially for the Mediterranean fruit trade, by Messrs. Murdoch & Murray, Port Glasgow, went down the Firth of Clyde on her trial trip on July 2nd last. She is a steamer of 1,200 tons, built to highest class in Lloyd's, and the machinery by Messrs. William King & Co., Dock Engine Works, Glasgow, is on the compound surface-condensing principle, the cylinders being 28 and 50 diameter by 36 stroke, fitted with expansion gear and all the latest improvements, steam winches for working cargo, &c. The speed on the measured mile was 12 knots, which was considered very satisfactory.

Arica.—The Pacific Steam Navigation Company's new screw steamer *Arica*, just completed by Messrs. Laird Brothers, Birkenhead, made her official trial trip in Liverpool Bay on July 5th. No runs were made on the measured mile, but between the Bar Light and Orme's Head the vessel maintained a speed of upwards of 12 knots, the engines indicating about 1.300-h.p. She had upwards of 1,000 tons weight on board at the time, and the results obtained were considered eminently satisfactory. The *Arica* is intended for the company's West Coast trade. She is built of Siemen's-Martin steel, and is of the following dimensions:—Length, 300 ft.; beam, 36 ft.; depth to maindeck, 19 ft. 6 in.; tonnage, 1.920 b.m. Ballast tanks are fitted to contain about 300 tons water, which is pumped out in a remarkable short space of time by a No. 8 Pulsometer pump. Like the majority of the Company's coast steamers she is constructed with an awning deck, and in houses on that deck is provided accommodation for a moderate number of passengers as also for captain and officers, but she has been designed principally for cargo and cattle traffic. The engines of Messrs. Laird's construction work at 90 lbs. pressure, and the boilers are of steel.

Fieramosca.—The *Fieramosca* (s), of Sorrento, Castellamare. ran her official trip on the Clyde on July 6th attaining a speed of 13½ knots, which is specially noteworthy, as she is only 133 ft. long over all, and built of scantling heavy enough to enable her to get Lloyd's 90 A 1 class. Captain Antonio Cocurullo is the owner. She is intended to carry up to 250 passengers on day trips in the Bay of Naples, and as seats all round on deck, with galvanised stanchions, and awnings, saloon, and cabins, smoking saloon on deck aft, and second class saloon below forward. She was built and engined by Messrs. Hanna, Donald & Wilson, of Paisley, and has steam windlass, separate ventilating engine for stokehole, &c., &c.

Craigallion.—On July 12th the *Craigallion* (s), 1,250 tons recently launched from the shipbuilding-yard of Messrs. Ramage & Ferguson, Leith, went down the Firth of Forth to have a preliminary trial of the engines. This steamer has been engined by Messrs. Muir & Houston, Harbour Engine Works, Glasgow, and the results obtained were of the most satisfactory description. The diameter of the cylinders is 26 in. and 50 in. by 33 in. stroke, and on a mean trial the steamer obtained a speed of 11½ knots, a result which exceeded the engineer's and builders' expectations. This steamer carries Emerson Walker & Co's. patent windlass and is owned by Messrs, Walker, Donald & Co., 13, Dixon Street, Glasgow, and is intended for the Spanish fruit and mineral trades. The *Craigallion* leaves in a day or two for Bilbao.

Chateau Lafite.—The screw steamer *Chateau Lafite*, 366·25 by 41·1 by 30·00, 3,462 tons gross, and 450-horse power, with cylinders 45 by 82 by 50 stroke, built by Messrs. Oswald, Mordaunt, & Co., Shipbuilders and engineers, Southampton, for the Compagnie Bordelaise de Navigation à Vapeur, Bordeaux, went for her official trial of six hours run round the Isle of Wight, on the 14 July, when, with a displacement of 4,400 tons, she averaged a mean speed of 12½ knots, with a strong tide against her for the greater part of the way. On the 21st she went her second trial for speed on the measured mile, with 1,600 tons on board, when she averaged a speed of 13·6975 knots; one run being 14·062 and the other 13·333. Her engines indicated 2,687-horse power. Everything working cool and satisfactorily. She left immediately after direct for Bordeaux. She is the pioneer of the new company's fleet, which is intended for service between Bordeaux and New York.

Constance.—On July 8th, the new unarmoured steel and iron corvette, *Constance*, 14 guns, recently launched at Chatham Dockyard, made her six hours' official trial at sea. The trial was of a very satisfactory character, the average speed being 14 knots per hour. The contract power of the engines was 2,300, but they worked up to 2,597. The revolutions were 110 per minute. There was not the least sign of hot bearings. The makers of the engines are Messrs. Penn & Sons.

Ville de Rome.—The official trial trips of this steamer took place on July 7th, and under the superintendence of Mr. Jules Montargis, representing the Compagnie Générale Transatlantique. She is the third of four similar steamers ordered by this company from Messrs. A. & J. Inglis, Pointhouse, and forms an addition to their Mediterranean fleet, which, though of very recent creation, now numbers about thirty vessels. The first eight of these vessels were built on the Clyde last year, and attracted some attention on accout of the smartness with which they were turned out of the Clyde yards. One of these eight, the two built by Messrs. Inglis, viz., the *Charles-Quint* and *Ville de Madrid*, have left the others far behind in speed and economy of fuel; and from the observations on the *Ville de Rome's* trial, she is not likely to fall short of the sister vessels.

Maurice Reunion.—On July 20th the *Maurice Reunion*, built by Messrs. Wm. Hamilton & Co., of Port Glasgow, for Messrs. Gravier & Co., Marseilles, had her trial at the measured mile, along Sea Reach, near Southend. This vessel, which has been constructed for the Mauritius trade, is 299 ft. over all, 36 ft. beam, and depth, moulded, 25 ft. 6 in. She is built on three deck rule, two being laid of iron, and has a long bridge amidships, under which is a saloon and accommodation for her officers and engineers. She has engines by Dunsmuir & Jackson. The following result was obtained on her trial, 10·50 knots with 70 lbs. of steam, and it was considered very satisfactory. A trial was made to ascertain the consumption of fuel, and the result showed a rate of about 13½ tons per 24 hours. The machinery during the trial worked with perfect smoothness, and the trial gave great satisfaction to all interested.

Armathwaite.—On July 19th a large number of engineers and shipowners assembled to witness the trial trip of a fine new cargo steamer, the *Armathwaite*, which has been built to the order of Mr. William Burnyeat, jun., of Whitehaven, by the Whitehaven Shipbuilding Company, Limited, made a trial trip from the Mersey. The vessel had been brought round to the river in June last to be fitted with her engines and machinery. The *Armathwaite* is intended for the general carrying trade, her capacity being about 2,300 tons. Dimensions:—265 ft. over all, breadth 34 ft., and depth 20 ft. 9 in. She is classed A 100 at Lloyd's, and has been built with a double bottom for water ballast. She has a full poop, deck-house amidships, topgallant-forecastle, and iron upper deck. The fittings are of the most modern description, and include Emerson & Walker's patent windlass, Taylor's steam winches, and Clarke's steam steering gear. Her engines, which are 160 nominal horse-power, have also been fitted by Messrs. Jones & Sons, and the working of the machinery gave every satisfaction to those on board. The greatest interest centred in the successful working of Turton's crank and Turner's boilers. The recommendation of the former is that it has the web cut in two so that the fibre of the metal possesses a greater strength, and the crank pins are not likely to score. The Turner boiler reduces the weight of the boiler to about one-half that of the old style, as well as reducing the cubical space occupied, and a consequent reduction in the quantity of fuel required to heat it. We shall in an early impression illustrate these boilers and the crank shaft. It must now suffice to say that the trip was in all respects a success. The engines gave no trouble whatever, although they had never been under steam before, save for a few hours at the dock side. They indicated 630-horse power with a pressure of 70 lb., and 67 revolutions. The boilers are intended to carry 80 lb, but they were fired very easily, as it was not deemed necessary to push the engines in any way. Mr. Turner's boiler is of the locomotive type, with a fire brick furnace instead of one with water legs. Although very little is known about this boiler outside of Liverpool circles, it has been gradually gaining in favour since it was patented in 1878. The number of boilers made and being made is now forty-five. The first of these boilers was made for the screw cargo launch *Bagieda*, built at the Canada Works, Birkenhead, to the order of Messrs. Herschell, African merchants, and under the superintendence of Messrs. Ashlin & Asbridge, consulting engineers of Liverpool. The vessel is 81 ft. long on the water line, 9 ft. 6 in. beam, 5 ft. deep moulded, and 3 ft. 2 in. draught of water loaded, the guaranteed speed being ten knots per hour. The engines are on the high-pressure non-condensing principle and of 13½ nominal horse-power, and are supplied with steam of 80 lb. pressure per square inch from a Turner's patent boiler, having 2172 square feet of heating surface, and a grate with 10½ square feet area. This vessel has now been constantly at work on the river Volta for more than two years with very satisfactory results, having steamed the distance of 90 miles in a little less than six hours, no current or tide at the time. The owners are now on the point of ordering a second vessel of larger size than the *Bagieda*, the machinery, and especially the boiler, to be on the same design. The second vessel fitted with these patent boilers was the twin screw tug and tender steamer *Gamecock*, built at the Canada Works to the order of Mr. Beckett Hill. This vessel is 155 ft. long by 25 ft. beam, and is fitted with two pairs of compound surface condensing engines of 180 nominal horse-power, which indicated on trial 1164-horse power. This vessel has now been above sixteen months at work, giving very satisfactory results upon a very small consumption of coal. The yacht *Mizpah* is now under steam on her second yachting season, since she has been fitted with a pair of compound surface condensing engines, and a Turner's patent boiler of 12 nominal horse-power, the working steam pressure being 110 lb. per square inch. The engines indicated 75-horse power on the trial trip. The *Nottinghill*, now on her voyage to Calcutta, is fitted with ten boilers, which are calculated to bear a working steam pressure of 125 lb. per square inch. The engines are of 570 nominal horse-power, and are to indicate above 3000-horse power. Two other and similar vessels are now being built for the same company. The tug steamer *Storm King* is fitted with two patent boilers. The engines are on the low pressure jet condensing principle, the boilers have been above six months at work, the results being very satisfactory, and the consumption of coal is said to be very much less than with the former boilers.

De Bay.—No doubt it will interest many engineers and shipowners to know that a series of close, crucial, comparative, and in every way trustworthy trials of the relative merits of the "patent De Bay" propeller and the ordinary screw is being carried out under the supervision of engineers appointed by the De Bay Patent Direct-acting Propeller Company. Messrs. Capper, Alexander, & Co. have recently added to their fleet a new vessel, which has been named the *De Bay*, and it is their desire, having carefully gone into the matter, to have this vessel fitted with a propeller, or rather pair of propellers, on the *De Bay* principle. The *De Bay* is a first-class cargo steamer, and reflects great credit on her builders, Messrs. Palmer & Co., of the Jarrow Shipbuilding and Engineering Works. She is an exceptionally strongly built, commodious, highly-finished cargo steamer. Her length is 250 ft.; beam, 35 ft. 4 in.; depth of hold, 23 ft.; and with a mean draught of 21 ft. she will carry some 2500 tons of cargo. Her engines are compound surface condensing, with cylinders of 30 in. and 55 in. diameter, respectively, having a stroke of 42 in., and are capable of indicating upwards of 900-horse-power; they are fitted with all the latest improvements in engineering, and in every part indicate the care they have received at the hands of Mr. Gibb, of the Jarrow Works, under whose direction they have been constructed. In the engine-room is to be found Durham's patent marine governor on a new pattern, in which he has abandoned the gearing to which some shipowners had objected. In this his latest design the water cylinder revolves, and its position on the main shaft or spindle—at right angles to its position in the original design—obviates of course the necessity for gearing to drive the internal fans. On deck the steel hawsers, on neat rollers, fore and aft, attract notice, and are for mooring a ship, a vast improvement upon the untidy, uncouth, and unwieldy cables, which for too long a time have retained their places on the decks of our steamers. The wheel-house is fitted with a steam steering gear, from the patented design of Mr. Nelson, and is worked from the upper bridge by means of a very small wheel. Should an accident occur to the little engine which works the steam steering apparatus, a lever may instantly through the apparatus into gear for steering by hand, for which purpose a large hand wheel is attached to the machine. We have said that Messrs. Capper, Alexander, & Co., had determined to have this ship fitted with the De Bay propeller, but in order that an absolute comparison might be made as to its behaviour, it was arranged that a common propeller should first be fitted to the ship, that trials under certain known conditions should be made, and that the *De Bay* should make her first voyage with it. At the conclusion of the first voyage the De Bay propeller will be attached, and trials will then be run under exactly similar conditions. On the 30th of June the first of the series of trials was made in the presence of several shipowners and engineers. On this occasion the steamship was unladen, having only water ballast on board. Several runs were made over the measured mile a little to the north of the river Tyne, runs at "full speed," "half speed," and "slow," the best speed obtained being at the rate of 10·97, or in round numbers 11 knots per hour. At the luncheon, after the "Success of the steamship *De Bay*" had been proposed by Mr. Gibb, duly honoured and responded to, Mr. Capper in felicitous terms proposed "Success to the De Bay Propeller," which toast was acknowledged by Mr. De Bay, who expressed himself confident that good as was the performance of that day, he would beat it very considerably under the same conditions, when the time came for trial with his propeller. On the 11th of July the second of the series of trials was carried out, the ship having then on board a cargo upwards of 2400 tons. Several runs were made over the mile at the same engine speeds as at the first trial. The highest average of the full speed runs was 9·50 knots, as nearly as may be and this may be regarded as an excellent result. At the conclusion of the trials the *De Bay* sailed for Cronstadt, from whence she returns to London, where she may be expected in a month. The De Bay propeller will then be fitted, and trials will again be carried out, when all the figures resulting from the trials will be made public. That Mr. De. Bay has an excellent performance to beat there is no doubt, but both he himself and Mr. Folkard, who is consulting engineer to the company, are confident of establishing the superiority of the De Bay propeller in point of economy of power with increased speed.

Correspondence.

[It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.—ED.]

"STATUS" OF H.M. NAVAL ENGINEERS.

To the Editor of the MARINE ENGINEER.

SIR,—In our last April number I see you quote a portion of an article from the *Engineer* concerning the "Status" of H.M. Naval Engineers. I am sorry that any of your readers should have allowed it to pass by without comment. May be, some engineer has answered the challenge in the columns of the above-named scientific paper, if not the sooner they do so the better, for that portion of the B. P. who know nothing of a "steamer" will readily believe that the duties of a marine engineer can be carried out effeciently by a locomotive driver. For the benefit of B. P. and the gentlemen who may probably again discuss this question in the next session of Parliament, I will quote an extract from the *Morning Advertiser* of January, 1877. Speaking of the kind and multifarious duties of the engineers on board H.M's. ships, the writer says, "It will rest entirely with him (*i.e.* the engineer) to inspect and surpervise the working of the big guns." Again, of the "Torpedo" which receives its motive power from the compressed air stored within it, which is forced into the interior of the machine with the aid of powerful air-pumps in the hold of the ship, he asks, "Who then is to take charge of these air-pumps and look to the filling of the torpedoes? The engineer has this duty to discharge, for the simple reason that it has to do with *mechanics*, and naturally falls within his sphere. As regards his minor duties connected with the opening and shutting of the bulkheads, and his responsibilities relating to fittings of all kinds, we say nothing; neither need we point out that in the case of mastless ships (iron clads) like the *Thunderer*, the burden of moving the ship, which rests entirely on his shoulders, is a most heavy and responsible one. Indeed it may well be asked, if the engineer has all this to do, what on earth do the other officers find to fill up their time with?"

I will quote again from another and more recent authority. On page 78, in the *Shipowner's and Engineer's Guide to the Marine Engine*, the editor of the *Engineer* will find the following, "A mere hammer and chisel man will ere long be a creature of the past; the advancement of the age demands something more from the sons of steam, and it behoves them during their apprenticeship to master the laws of heat and the principles of mechanism."

The idea of doing away with the present system, and to have *one clever man* to manage the whole of the duties, assisted only by "hammer and chisel" men, must be absurd to any one having the faintest knowledge of engineering. Equally absurd is it to find a parallel between the marine engineer and the locomotive driver. The former is compelled by the Admiralty and the Board of Trade, to appear before them and to satisfy them, that their terms of apprenticeship have been completed, and that their knowledge of mechanics is sufficient to make good any repairs and defects which may be required to be done at some foreign port, and without the aid of a factory. The mere "driver," takes, as it were, his engine from one shop to another in a few hours' run. There is not sufficient time for any serious "wear and tear," before his engine is again in the shop and overhauled. The only parallel between the two duties, as far as I can see, is in the amount of presence of mind required in times of accident, for which quality there is no test, nor can there be, for it is a natural gift, and cannot be acquired by any kind of "coaching." With regard to the great amount of responsibility of the "driver," this applies equally to the "signal man," then according to our friend's argument, the latter should be paid as high a salary as the "engine driver" or "engineer!" Then again, this argument might be taken home to himself, or to a "bishop" or a "lawyer." Supposing the Archbishop of Canterbury neglects his duty, is there a life lost, or a thousand pounds worth of property destroyed? No! of course not. Then why should he have such immense remuneration? Men are remunerated in proportion to the cost and time of their education, and not according to the immediate responsibility of their "callings." No doubt, sir, you may throw more light on this subject, and be able to tell the "public" that the marine engineers are not adequately paid, neither have they the "status" they are entitled to, either in the navy or the mercantile marine, but the day is coming when their true positions must be acknowledged, and their pay and privileges made equal to a clerk's at least.

I am, sir,
Your obedient servant,
"A WOULD BE RULER OF THE QUEEN'S NAVEE."
July, 1881.

STEAM YACHT COMPETITION.

To the Editor of the MARINE ENGINEER.

SIR,—In *The Field* (May 21 and 28) Mr. Dixon Kemp has furnished communications on the subject of steam yacht competition, and justly refers to the great and increasing interest that exists in the performances of this character of vessel. In view of the total absence of any recognized standard of comparison of powers and the manifest necessity of one Mr. Kemp very properly assumes as follows:—That their competitive performance is confined to their hulls and machinery, or, in other words, to their model and power, the value of the former being the least resistance for like displacement; and of the latter, greatest effect with least consumption of fuel.

In order, however, to arrive at these results, he proposes for the comparison of hulls to attain their displacements by a formulated computation of displacement of uniform application for all designs and proportions of hull, and for the comparison of power he holds, it would be preferable to note that indicated by a performance of the engine at an assigned time under the observance of an engineer appointed for the purpose. Yet in order to meet evasions on the part of the engine drivers, who would essay to develop the least power commensurate with the capacity of the yacht, he prefers and submits a general rule, simple in application and which he considers to be sufficiently accurate for the purpose. This rule is based upon the assumption that cylinder and fire grate only are the elements of comparison, as water and coal consumption can be taken as identical, and to attain these elements he proposes to arrive at the mean indicated power (IHP) by the following formula:—

$$\frac{d^2 \div 4 + 10A}{2} = \text{I H P}$$

d representing diameter of cylinder in inches, and A area of grate in square feet. And, in connection with this, he deduces a coefficient of performance by the adopted formula of

$$\frac{S^3 D^{\frac{2}{3}}}{\text{I H P}} = \text{coefficient.}$$

D, representing displacement in tons, and gives 215 as a mean, obtained by results of various trials; and in order to compute the speed when the other elements are known he gives

$$\sqrt[3]{\frac{\text{I H P} \times c}{D^{\frac{2}{3}}}} = \text{speed in knots per hour.}$$

In view of a general coefficient being inapplicable to the varied ranges of displacement he proposes to meet this difficulty by dividing the yachts into a great number of classes, and in the case of extreme ranges of tonnages, instead of deducing a coefficient for $D^{\frac{2}{3}}$ he proposes $\sqrt[3]{D^{\frac{2}{3}}}$, or to correct $D^{\frac{2}{3}}$ by an equation varying as the sixth root of displacement.

In support of these views a Table of the actual I H P, and as computed by his rule, is given. An examination of these, however, shows that their differences range from 1.2 to 32 per cent.

The propriety of the position taken by Mr. Kemp as to the basis of comparison of steam yachts is not to be questioned: it is patent to consideration; but of the justness of his methods of arriving at both of these elements I differ with him widely, and in support of my views I submit the following:—

His method of obtaining the displacement is without regard to the particular outlines and dimensions of each case, except so far as the registered tonnage of the entire hull is assumed to include such peculiarities as may intervene in its six divisions of length and five of depth, and from which its volume is computed.

All vessels are constructed from dimensions arrived at by their lines and sections being extended to full dimensions upon a moulding floor, and from thence they can be taken by reduced dimensions and transferred to paper, from which not only the displacement of the hull can be computed to an assigned water line, but a scale of displacement can be obtained for every depth of immersion, from rabbet to sheer strake, and this diagram signed by the constructor of the hull and filed with the club to which the yacht belongs should be held as accepted authority for the displacement. In this manner, then, I propose that the indispensable element of displacement could readily and correctly be obtained. Regarding an estimate for the comparative powers of engines it is desirable not only to reduce the elements to the least practicable, but to avoid all having variable proportions, thus restricting the elements to those only of comparison. Hence the incorporation by Mr. Kemp of the diameter of the steam cylinders with the area of grate in a computation for comparative power of two yachts is not only unnecessary, but erroneous; thus, with two yachts of like models and draughts of water, with like boilers and consumption of fuel, cylinders of like stroke of piston but differing in capacity (proportional to the pressure of steam the owner or builder may prefer to operate with), and, consequently, in their diameter, and assuming grate 50 square feet, cylinders of No. 1, 20 and 36 in. and of No. 2, 26 and 46 in.; then by rule:—

$$\begin{array}{rrcrr}
\text{No. 1—}20^2 = & 400 & \qquad & \text{No. 2—}26^2 = & 676 \\
36^2 = & 1296 & & 46^2 = & 2116 \\
\hline
4) & 1696 & & 4) & 2792 \\
\hline
 & 424 & & & 698 \\
50 \times 10 = & 500 & & 50 \times 10 = & 500 \\
\hline
 & \dfrac{924}{2} = 462 \text{ I H P} & & & \dfrac{1198}{2} = 599 \text{ I H P.}
\end{array}$$

But by actual operation their powers would be essentially identical. Hence, with like vessels and powers under the operation of this rule one would be penalized for power 34 per cent. above the other.

In additional illustration of the preceding formulæ I submit the following elements of a yacht with which I am familiar:—

$D = 181$; $S = 14$ and $I\ H\ P = 460$. Then $14^3 \times 181\frac{2}{3} \div 460 = 87808 \div 460 = 190.8$, coefficient, and

$$\sqrt[3]{\frac{190{\cdot}8 \times 460}{181\frac{2}{3}}} = \sqrt[3]{\frac{8780{\cdot}8}{32}} = 14 \text{ knots.}$$

If, therefore, an assigned coefficient of 215, as submitted by Mr. Kemp, was taken in this case, her capacity for speed would be computed at

$$\sqrt[3]{\frac{215 \times 460}{181\frac{2}{3}}} = 14{\cdot}57 \text{ knots,}$$

by which she would be charged time 4 per cent. in excess of that due to her power and displacement, = one knot in 25.

As the combustion of the fuel in a boiler is the source of the power of an engine, the surface area of the grate alone, but for the varying methods of combustion as by natural draught, steam jet, exhausting draught, or pressure blast, could with propriety be taken as the exponent or measure of that combustion, and hence a measure of the power could very easily be arrived at. To make the grate surface then of uniform value, when the combustion under the methods above given would vary from 13 to 25, and even to 40 pounds coal per square foot of grate per hour, is an operation not to be entertained; consequently, the rule of measurement as submitted by Mr. Kemp, wherein the grate surface, independent of the method of combustion, is taken, fails to meet the requirements of the case.

A review, then, of the elements existing and of their operation furnishes the following:—

1. Displacement of the hull can readily and correctly be arrived at by the possession and computation of a scale displacement.

2. The exact powers of the engines of competing yachts can only be arrived at with full satisfaction to all parties by the result of the observation and operation of a committee of at least three engineers, whose duty it would be to examine condition of flues and grates of boilers, condition and adjustment of engines, to require the use of coal of an average quality, and to operate the boilers and engines to their full capacity, and to obtain indicator cards from which their powers could be correctly computed and taken as standards thereof.

3. If the preceding method should be objected to because of the details involved, or impracticable at certain localities for want of all the necessary experts, a very practicable and a fair result can be arrived at by the assignment, by a committee of engineers, of a standard evaporation per square foot of grate for the different methods of combustion, computed in combination with their capacity of cylinders and ratio of expansion.

4. If objection should be entertained in consequence of making the boiler the essential element of determination of power, I hold that, inasmuch as the combustion of the fuel is its source, and that the only variable elements connected with it, when of a like composition, are the methods of combustion and the type of boiler, that the design and its proportions and consequent consumption of fuel are as essential and equally as fair a test of merit in the general design and construction of a steam yacht as that of the area, location and trim of sails in a vessel designed for canvas alone.

5. The comparative propelling capacity of steam yachts can be obtained by taking the surface area of their grates at natural draught, adding thereto an assigned factor for the different methods of jet and blower combustion, all of which can, with all necessary exactness, be deduced by a committee of engineers.

6. Having obtained displacement and power, it then becomes necessary to apply them to the requirements of competition, and in order to attain this, it must first be determined whether allowance of time is to be made for an assigned distance run, per speed, or per time per hour; and second, what this allowance should be. And these are results that can be only justly arrived at by being confided to the decision of a combined committee of expert engineers and yachtsmen.

The problem, then, of how a just standard of comparison of the powers of steam yachts and the allowances therefor are to be readily and satisfactorily arrived at I have not assumed to solve or to indite rules for, but in contributing to the elements by which the solution and rules are both to be reached I have essayed, in compliance with your request, to facilitate the attainment of so desirable a result.

CHAS. H. HASWELL.

Notes and Novelties.

Eddystone Lighthouse.—The New Eddystone Lighthouse is to be provided with two fine bells of two tons weight each, and the Trinity House has commissioned Messrs. Gillett & Bland to cast them. Their dimensions are:—Height from shoulder to lip 3ft. 8 in.; total height from lip to upper surface to the mushroom suspender, 4 ft. 6 in; diameter at shoulder, 2 ft. 10 in.; diameter at lip, 5 ft. 1¼ in. In the foundry at Croydon a large number of visitors witnessed one of the Eddystone bells already cast, undergoing the process of bright turning of the upper part; presently it will be turned bright along a portion of the lower part for the sake of ornamentation. When this is done the bell will be up-ended and tuned to a perfect note. All bells are cast with their notes sharp, and the flattening of the note is then accomplished by turning away more or less of the inner surface of the lip. To sharpen a bell's note there must be a slicing away from the lip, and this cannot be done to any extent. In the foundry, also, were specimens of moulds of bells in perfect series, and ingots of the bell-metal of which the new bell—the second Eddystone bell—was to be cast. Here in the metal a marked advance is made. The alloy is carefully made by puddling in a reverbatory furnace, so that it is already a very perfect alloy when it is cast into ingots. These ingots are again put into the reverbatory furnace for the casting charge. At about a quarter to five the casting charge was ready for running; the moulds were all finished up, and the leading trough loamed along its length. The foundry was crowded with visitors, the ladies being not less than equal in proportion, and displaying lively interest in the proceedings, and very intelligent appreciation of the different operations. The furnace-stopping being broken in, the dull red highly fluid metal poured forth, disappearing into the depths of the mould for about a minute and a half; it then rose bubbling up and filled the upper spaces, forming two hot lakes above the casting. These are intended to give a head or weight of metal to render the bell homogenous and firm in structure when cold. Two or three extra crucibles of molten metal from auxiliary pits were poured in, making altogether 48 cwt. or 50 cwt. of metal. The work was performed by four men without a hitch of any kind, and the promise of a very fine bell will, we doubt not, be duly realized when the bell is exhumed.

32, Basinghall Street, London, E.C.

THE German Admiralty has decided upon the construction of a number of gun-vessels of an improved type. They will be armour-plated, and armed with one large gun and six machine guns, and two ports for discharging fish torpedoes. The tonnage is to be 950, with indicated horse-power of 1,400 horses which, it is calculated, will give a speed of over 14 knots.

EDITORIAL NOTES.

It seems that we are yet but novices in the art of naval architecture. Such a statement may sound absurd to those experienced men whose lives have been spent in wave theories and most perfectly proportioning the hulls of the present day. But what do such constructors say to a vessel which shall steam at a speed of 30 to 40 knots, with only a moderate exertion of power. This, they will be inclined to say is a chimera, but this result seems to be brought at least within the bounds of possibility by the researches and experiments of Professor Raoul Pictet, of Geneva. The invention of the Professor follows the idea of the familiar "duck and drake" of a flat stone. That is to say, he has conceived the idea that high velocity should be utilized to raise the vessel out of the water rather than to force it through the water with an increased immersion. The Professor has succeeded in constructing a model, which demonstrates the easibility of this idea with a certain construction of hull. The immersion at the bows is reduced from 6 to 3 inches at speed, and proportionately throughout the length of the hull. The vessel is driven by a pair of side paddle wheels. Should all these results be confirmed by further constructions on a larger scale, this invention promises to revolutionize marine construction—at least for speed.

The submarine torpedo boat invented by the Roumanian engineer, Trajan Theodoresco, which we have already referred to, seems to be an accomplished success. We understand that the boat may be navigated under water at a depth of 100 feet for 12 hours at a stretch. She can, however, descend without difficulty to a depth of 300 feet. On the surface of the water the boat can be manœuvred under the ordinary conditions of a steam-boat. She is not, however, very fast above water—not exceeding 8 or 9 knots an hour. She has the specialty of providing her own light when immersed. She can project the light, so as to show obstacles clearly at a distance of 130 ft., so that there is time to avoid them. The air supply will last for from 12 to 14 hours, and it can be renewed from the surface by means of a telescopic tube and pumping apparatus. The propulsion of the vessel, and its submersion are effected entirely noiselessly. A vessel, having all these peculiarities would certainly prove a most dangerous foe, and might be turned to profitable account in times of peace by diving for sunken treasure, or the light movables on board sunken vessels.

China is fast disabusing the Western World of their idea that she is too stupid or conservative to graft modern inventions upon her antique systems. It is mostly, however, in her Navy that the greatest strides have been made. Her junks have proved much more seaworthy and enterprising than would be at first imagined. She is, however, fast replacing her ancient war-ships by the latest improvements in gun-boats. These gun-boats, though small, are the most powerfully armed iron-clads in the world. She is now purchasing heavy guns from the great founders at Essen, and a large consignment of fish torpedoes from the Schwartzkoff works at Kiel. It is noteworthy that her first great advances are in warlike arms, and it is frequently to be noticed that this is the first assumption of civilized manufactures by barbaric nations. It is to be hoped that these first essays towards civilization will be followed by the adoption of other inventions of Western ingenuity, tending more directly towards commercial advantage and progress.

WE understand that a Mr. Sayers is advocating the adaptation of air bags to the sides of a ship as a protection against sudden sinking. To effect this purpose large air-bags of suitable water-proof or impervious material are enclosed in a string or cord netting attached to a strong rope. The rope passes over pulleys, one at the bottom of a strut, which projects from the side of the vessel, and others so placed that the cord runs inboard on deck. When not required the strut lies flat against the ship's side, and the bag, we presume, is laid by, flat, out of the way, on deck. Should any serious leak occur, a number of bags may be rapidly blown out, and lowered over the ship's side, the struts at the same time being fixed so as to support the air bags clear of the ship's side. As the bags may be blown out and lowered in a few minutes there does not seem much danger of vessels sinking suddenly for the future. This is provided that the air bags, of which we do not doubt their buoyant power, and their attachments are strong enough to support the vessel to which they are attached.

MUCH work in marine foundations is now effected by the discharge of rubble or concrete blocks on the chosen sites. This method of construction is found equally effective and much more cheap and rapid than construction behind dams or in caissons could ever be. To effect these operations the rubble or concrete are conveyed by barges from which the rubble is discharged by spade or crane labour. We note a very ingenious invention from America in the screw or barge for such a purpose, may be made in two watertight compartments jointed in the centre, which are made to open along the line of the keel by suitable gearing, the load being discharged downwards through the opening so made. The interior lining or deck of the barge is made in a double incline towards the keel, showing when the barge is closed to receive its load a V-shaped hold into which the material is filled. The barge is held fast in this position by suitable catches. When these catches are released the weight of the load itself suffices to force aside the two hinged watertight compartments of the barge, and allows the material to fall through the opening thus made in the keel.

THE discussion raised by Mr. Price on the comparative value of cargo-carrying vessels built in steel or iron is one of the greatest interest to ship-owners and builders. It is strange that such an important discussion was not aided by the opinions of ship-owners, ship-builders, and sea-going engineers, rather than restricted to the views of a body of merely mechanical Engineers. Mr. Price, the general manager of Palmer's Shipbuilding Company, one of the few of those discussing the question who had thorough practical knowledge of his subject, advanced many weighty arguments in favour of the theory that an iron built ship pays the ship-owner better as a general cargo-carrying vessel than a steel-built one. We are certainly inclined to agree with him, for many reasons. First and foremost the first cost of an iron vessel will average at least £3 a ton cheaper than if it were built in steel, and there must be a great advantage in either long life or increased cargo capacity to pay for such an extra outlay. We may suppose that the relative strength of an iron and steel vessel with the above mentioned difference of cost, are about the same, so that we must look elsewhere for the advantages. We fail to see where, for average cubic capacity cargo, the steel ship 10 per cent. lighter is able to carry an equivalently larger cargo. We know that, in average times the difficulty is to get a sufficiency of cargo at all, and not how to carry a 10 per cent. heavier cargo than usual. Very often this could not possibly be done even if freights were plentiful, as frequently the cubic capacity is crowded long before the maximum dead-weight cargo is reached. The only exceptions to this would be in the case of dead-weight cargoes of ore, but the dead-weight cargoes are, we should imagine, but a very small proportion of the average cargoes. That iron ships amply pay for their extra cost over wooden vessels is amply evident from the practical indestructibility. We know of some of the first iron cargo vessels which have been running nearly thirty years, and are practically, with a few repairs, as good as ever. With steel there is no proof that any longer life can be obtained, and there is thus no advantage left that we can see except greater speeds for passenger vessels and greater capacity for dead weight cargoes only.

ASBESTOS PACKING.

THE United Asbestos Company, Limited, seem to be rapidly developing their business, as we have received a notice of their removal to more extended premises at 161, Queen Victoria-street. This Company thoroughly deserve their success from the principles on which they transact their business, viz., to supply only the best and purest article at a fair price.

Asbestos has been much tested and tried lately for gland packing and high pressure steam joints, and many are the different reports about it. Some find it admirable and practically indestructible. Others, however, say that the packing they have used has broken to powder under pressure in the gland, and blew away very much to the injury of the machinery and their own lungs. In some cases, too, we have heard instances of deep corrosion reported as occasioned by asbestos packing.

We think we can do good service to those who may have experienced these disadvantages by telling them that asbestos differs in its fibre and quality from different mines as much as iron or any other mineral. To obtain strong and tenacious, then, a fair price must be paid for it, and the right article found. The United Asbestos Company have the credit of possessing all the best Italian mines, and make an asbestos with a long, tough fibre. The best thing an engineer can do is to try it.

The corrosion also is frequently and chiefly caused by the impregnation of acid in the fibre which had been used to clean the fibre instead of mechanical means, as it may have been too tender to withstand mechanically cleaning.

This danger again the United Asbestos Company avoid by using no acid at all in the cleaning of their fibre. These points are worth knowing, as a valuable material such as asbestos has been frequently discredited by the failures of inferior qualities.

CORNISH'S LIFE-SAVING APPARATUS.

SOME further interesting experiments with this apparatus have recently been conducted at the Charing Cross Floating Swimming Bath. This apparatus we have already favourably spoken of, and Mr Cornish's many years' devotion to rendering articles of ships' furniture capable of supporting swimmers at sea, deserves substantial recognition at last. The floating mattresses each suffice to support one or two persons, and when combined in a raft would form a most buoyant and valuable means for saving life. The seats and cushions of steam-boats, yachts, or pleasure boats could be all so constructed as to enable one or more individuals to float with safety on the water.

The pillow life-belt is a most useful and handy article, which can be instantaneously attached to the body, and will ensure the support of the swimmer in the proper position, and not feet uppermost, as is too frequently the case with ordinary life-belts.

The life-buoy, as patented by Mr. Cornish, is quite different in shape to the old fashioned circular one. It is something in the shape of the letter H. The swimmer to be supported rests easily on the middle bar, either on his chest or back, and thus has his arms free with which to signal, as his body is supported far out of the water. Mr. Cornish demonstrated at the Baths the ease with which a drowning man could be rescued, when the rescuer was aided by such a life-buoy. In one of the experiments, as many as four persons were hanging on to the life-buoy and were easily supported.

The mattresses are so buoyant that one of them supported a weight of 42 lbs. as well as a man. As these mattresses and ship-fittings do not cost more than those usually supplied, there is no doubt that the public would be sufficiently appreciative of such an extra guarantee of safety to more than repay a ship or boat proprietor for his enterprise in adopting these useful fittings.

MILD STEEL IN FRENCH ARSENALS.

On the Use of Mild Steel for the Construction of the Hulls of Ships in the Arsenals of the French Navy.

By M. MARC BERRIER FONTAINE, Member.

(*Continued from page* 105.)

I HAVE collected an account of the ordinary prices paid in the French Navy for the steel of different shapes used in it, these prices having been calculated from the different tenders accepted by it during two different biennial periods, the first comprising the years 1873 and 1874, during which the use of steel was largely developed for the construction of the ships of the fleet, the second period comprising the last two years 1879 and 1880. A comparison of the mean prices thus brought together shows that in the interval of six years, which separates the two periods named, the mean price of steel plates has fallen 56·2 per cent., and that of steel angles 46·2 per cent., while the price of moulded steel bars, not being angles, has only diminished during the same interval of time by 11 per cent. I have also collated, for the sake of comparison, the mean price of iron of different shapes which has been delivered to the Navy in compliance with a certain number of contracts entered into on its behalf during the last year. Finally, I have applied all these mean prices, obtained as I have said, to the total quantities of plates and moulded bars, both in steel and iron, which have been actually ordered for the construction of the hull of the first-class ironclad, the *Foudroyant*, and I have calculated within what comparative limits the total weight and the total cost of the material would be altered in each of the two hypotheses following, first, supposing this particular ironclad to have been built entirely of steel, including even the exterior part of the hull, or, secondly, altogether in iron. It appears from this comparison that if we took severally for unity the total weight and the total price of iron which would have been required in a case corresponding to the last of the preceding supposition, the substitution of steel for iron in all parts of the construction, with the exception of the external plating of the hull, would permit us at the present day to effect a saving in weight of 17·1 per cent., and a saving in cost of 7·7 per cent., while if, moreover, the external plating of the hull had been also made in steel, the savings in question would have become as follows: in weight 20 per cent., and in cost 12·4 per cent. I cannot drop this subject without pointing out besides, that a fighting ship is not, like the merchant ship, obliged to carry a cargo of which the weight must be left undetermined within certain limits, subject only to its being possible to retain the same displacement when fully loaded, with the same dimensions and the same external form when the weight of the hull is either increased or diminished more or less, provided always that this increase or diminution of weight in the hull is compensated for by a corresponding diminution or increase in the weight of the cargo. A ship of war, on the contrary, is constructed to fulfil certain perfectly determinate conditions; to carry, for instance, an armament of which the total weight is exactly fixed beforehand, and which cannot be reduced without bringing about a corresponding reduction of one at least of the qualities which have been accepted as necessary. The weight of the hull of such a ship cannot therefore be increased without involving, as its necessary consequence, a corresponding increase of capacity, and again in the weight of the driving machinery, if we wish the enlarged ship to retain the same speed; and, further, an increase in the coal supply if we wish the ship to be capable of steaming the same distance, and so forth; that is to say, we are involved in a whole series of increments which all tend towards the same result—a considerable increase in the dimensions and total weight of the ship when ready for sea. If, for example, the hull of the *Foudroyant* had been built of iron instead of steel, it would have been necessary to increase its dimensions considerably, and we cannot estimate this increase at less than 1,600 tons for the load displacement.

I do not think it is necessary to reason out any further these considerations in order to put in a clear light the importance of the marked saving which the substitution of steel for iron now permits us to secure for ships of war. As I have said before, the constructors of the French Navy have thought it necessary, up to the present time, to adhere to the use of iron plates for the outer plating of the hulls of all vessels of any importance which form part of the fleet. The difficulties which we formerly had to encounter in fashioning steel plates into the abrupt and varying forms which had to be given to the garboards and to the plates at the two ends of the ship, difficulties pointed out in 1875 by M. Barba,[*] must not be looked upon at this day as among the reasons which still actuate the directors of the Navy in not carrying the use of steel into the parts in question, but that it is clearly shown that steel plates can practically be brought to such shapes if they were suitably treated.

Among the reasons which were formerly stated for retaining the use of iron in the exterior plating of the hull there is only one which still exists, and that is the uncertainty which still remains as to the behaviour of steel plates in sea-water. It must be admitted that the experience of the French Navy, although by no means very extensive on this point, is not very favourable to the abandonment of iron plates for the special purpose in question, for there is evidence that steel plates, when wetted with sea-water, rust much more quickly than iron plates do under similar circumstances. It also appears that the conditions on which the corrosion of steel plates depend are extremely complex, and that they are, for instance, much more active in the comparatively warm water of the Mediterranean than in the colder water of the ocean. I will quote as examples two gunboats, the *Epée*, built at Lorient, and the *Tromblon*, built at Toulon, whose hulls, completely steel-plated, have each of them given proof of rapid and deep corrosion. The *Epée*, however, could be kept afloat in the brackish and muddy water of the port of Lorient formed by the Scorff river. The *Tromblon* was launched at Toulon on the 20th January, 1875, and remained afloat until the 27th October of the same year. During that period of nine months it has been necessary to dock her three times, that is to say, about every two months, to paint the hull, the plates being so rapidly and deeply attacked, especially in the neighbourhood of the water-line. Instead of spreading more or less uniformly over the whole surface of the plate, as usually happens with iron hulls, the oxidation seemed to spread by preference in the direction of the thickness of the plates from the points which were first attacked, by forming a series of pittings of great relative depth, and if there had been any considerable delay in re-painting the hull in the neighbourhood of the water-line, the plates, the thickness of which does not exceed 5 mm., would have been quickly perforated at a good many points. Finally, the progress of the corrosion of this steel-plated hull went on with such unusual rapidity that when the time came to pass the *Tromblon* into the reserve, it was thought necessary, instead of keeping her afloat, to haul her on to a slip, where she will be kept dry until fresh requirements of service oblige her to take the sea again. It is very likely that the true causes which govern this phenomen of exceptionally quick oxidation in steel plates wetted with sea-water will one day or other be completely investigated. When the causes of the evil have thus been determined it may be easier to find a remedy for it, but it must be admitted that the experiments which have been made on the subject at various places have not yet given very conclusive results. It would not be safe to affirm very positively, for instance, that this extremely rapid corrosion of steel plates is solely due, as Mr. Barnaby[†] assumes, to intense galvanic action arising between the metal and the black oxide by which it is covered, and that consequently it will be sufficient to clear the plates of this black oxide by means of a weak acid bath in order to make their oxidation in sea-water slow and uniform, like that which usually takes place on the surface of iron plates. It could not be affirmed with any certainty either that the greater or less rapidity with which steel plates are attacked by rust depends solely on the greater or less proportion of manganese which they contain, as has been suggested by Dr. Siemens, in 1878, in a paper read before this Institution, a suggestion, however, thrown out with some degree of doubt.[‡] Finally, it cannot be affirmed, as has been recently stated before another society, that the corrosion of iron and steel plates is the more slow and regular in proportion as those plates contain a greater proportion of carbon or phosphorus, and that it is consequently not possible to find plates which possess the necessary ductility in combination with the valuable property of being attacked by rust only in a slow and regular manner when exposed to sea-water.

The very diversity of opinion which I have just mentioned proves clearly that these statements can only be received as suppositions agreeing more or less roughly with the observed facts. Whatever be their real value, the French Navy, paying attention principally to the positive lessons of experience, acts doubtless prudently in refusing to substitute steel for iron in the external plating of its ships while there remains any uncertainty as to the causes which bring about on the surface of steel plates in sea water such abnormal corrosion as has been observed upon the hull of the *Tromblon*, and until we discover more effective methods of guarding against such deep and rapid corrosion.

Finally, I must point out, in a few words, what are the reasons which have until now decided the French Navy in retaining the exclusive use of iron rivets to fasten together the various parts of these new constructions in steel, although in reality these reasons do not differ materially from those which have been several times stated before this Institution, especially in 1878, by Mr. White and by Mr. John, in the discussion which followed the very interesting communication of Mr. Martell "On Steel for Shipbuilding."[‡] The French constructors are, like them, very far from assuming that the use of steel rivets may not some day give satisfactory results; but the cases in which steel rivets have hitherto been used do not seem to them sufficiently numerous, nor does the experience which results from them appear to have been sufficiently extended, nor sufficiently conclusive, to allow them to consider themselves in a position to dispense with the use of iron rivets.

As Mr. White pointed out very justly in the discussion which I have mentioned, on the use of iron rivets to connect the different portions of a steel frame, if we wish to preserve, as is suitable, the homogeneity of resistance in the joints, that is to say, equality of resistance between the rivets and the plates, it is only necessary to increase, in a very small ratio, the diameter of the rivets, or (which is preferable) the number of the rivets with a slight diminution of pitch. This proportionate increase may evidently be the less, accordingly as the tensile strength of the iron, of which the rivets are made, approaches that of steel. Now the French Navy only uses in its rivets—the whole of which are manufactured in its own yards—scrap iron, charcoal-made, and of quite exceptional testing. To be accepted, this iron must undergo with success severe forge tests and rivetting tests as well as breaking tests, in which the tensile strength or fracture must not come out below 35 kilogrammes per square mm., the corresponding elongation never being allowed to fall below 12 per cent., while the results actually obtained in these last tests usually indicate a tensile strength at fracture of from 38 to 42 kilogrammes per square mm., with a mean elongation of nearly 20 per cent.; that is to say, coefficients of tensile strength and elongation not much below those of the mild steels which could alone be substituted for the iron in question as material for the rivets. It will be easily understood that, this being the case, the French Navy would apparently gain no advantage, so far as at present appears, from substituting steel for iron as the material for rivets, and that it consequently prefers to go on making use of iron rivets of the best quality, which offer a better guarantee of security than could at this date be found in the use of steel rivets.

ON IRON AND STEEL AS CONSTRUCTIVE MATERIALS FOR SHIPS.[*]

By Mr. JOHN PRICE, of Jarrow.

THE object of the present brief paper is to bring into greater prominence than has hitherto been done, the question as to whether it is more economical, for commercial purposes, to build vessels of steel rather than of iron.

This subject has already received considerable attention, but probably not precisely in its relation to the class of vessels chiefly built in the Tyne district, which are essentially cargo carriers. The author will at once assume that a vessel, whether a sailing vessel or a steamer, has, commercially considered, two functions; firstly, to carry her cargo safely and efficiently, and, secondly, to carry it remuneratively to her owner. It is not pertinent to the present inquiry to consider the first of these functions further, it being of course granted as a necessary condition to the second. The iron vessel will therefore be taken as the standard of comparison, both as to cost and sufficiency of structure. The question really is, which of the two descriptions of vessels—steel or iron—can be shown to be the best investment. If we further narrow the question, it takes this form, in which of the two vessels, taking the dead weight or cargo-carrying capacity into account, can the ton of dead weight capacity be got at the lowest cost; for, as this is the unit upon which the ship's earnings are based, it must also be the unit upon which the cost is estimated.

[*] Paper read before the Institution of Mechanical Engineers at Newcastle

The company with which the writer is associated has recently built a vessel of the general description given in the Appendix; and it is proposed to take this vessel, as built of iron, for comparison with a similar vessel, but built of steel, so far as it is practicable to adopt steel instead of iron in her construction, thus securing the reduction allowed from the iron scantlings in use. The reductions take effect only on the material forming the hull of the vessel; and it will be seen from the particulars of the iron vessel in the Appendix that this material amounts to 1179 tons. From the similar particulars relating to the steel vessel, it will be observed that the equipped weight, which in the iron ship is 1740 tons, is 1614 tons in the steel vessel (after allowing for the difference of weight between equal volumes of iron and mild steel); the difference being thus 126 tons. This difference will also be found in the dead weight carrying capacity, on 22 ft. mean draught. It is only by increasing the dead weight carrying capacity, that any commercial advantage is secured by the owner, in adopting steel instead of iron. This is a point upon which there is no question, assuming, of course, that the iron ship is in every way a structure fitted for her purpose. We have, therefore, to inquire under what conditions this 126 tons of additional dead weight capacity has been obtained.

In the first place, in water ballast trim, the steel vessel would draw 6 in. less water. To put her down, therefore, to the same draught as the iron vessel would require her tanks to be increased in dimensions; and, to preserve the same trim, this must mean increased height of tank. As shown in the Appendix, the additional weight of material used in raising her tank to this height would be 8 tons, which would reduce the available additional dead weight from 126 to 118 tons. The effect of this increased water ballast accommodation would further entail the loss of 2900 cubic feet of stowage capacity, equal to 64 tons of stowage capacity, at 45 cubic feet to the ton.

The next and most important condition, under which the net increased dead weight capacity would be obtained, arises from the higher price that would be paid for the steel, as compared with the iron used in the construction of the hull. Before entering upon this, it may be well to state that the reduction of weight, estimated as due to the use of steel, is 14 per cent. of the weight of the iron vessel, which is about the largest rate of reduction found attainable in practice, as recently stated by an eminent Clyde shipbuilder, who has built a very large amount of steel tonnage. The increased cost of the hull is shown in the Appendix (with the additional cost of the extra water ballast required, namely, 8 tons at £9 12. 6d. less discount, and labour at £3 2s. 6d. per ton, total £100) to be £2760; or at an average rate for the 118 tons extra dead weight capacity of £23 8s. per ton. Now we may assume with perfect safety that the iron steamer, such as is described in the Appendix, could be built and equipped ready for sea, including all cost of engines, boilers, &c., for £10. per ton of dead weight capacity. This would make her price for 3235 tons dead weight capacity to be £32,350. Add to this £2760 for the extra cost if the vessel is built of steel, and we have £35,110 as the cost of the steel vessel, for a dead weight carrying capacity of 3353 tons. This shows the average cost per ton of deadweight to have been increased from £10 to £10 9s. 6d., or an increase in the entire cost of 4¾ per cent. In this example, therefore, we have, in addition to a loss of nearly 2 per cent. of cubic capacity, an enhanced cost of 4¾ per cent. per ton of deadweight capacity.

The question of using steel is sometimes considered differently. It is said that the increased dead weight so obtained is a gain of dead weight capacity, which does nothing but earn money, and against which no current charges need be brought, since it is obtained by a simple change of material in construction; and that at an assumed freight, which must be all profit, it will quickly pay for its acquirement. The cost, however, of this increased deadweight is seen to be £23 8s. per ton, whereas the dead weight in the iron ship is acquired at the rate of £10 per ton. It would appear at first sight to be a complete answer to what has been said about this earning property of the acquired dead weight, to point out that the same effect can be obtained by increasing the dead weight capacity of the iron vessel at £10 per ton, instead of £23 8s., the cost of the same in steel; with precisely the same property of earning, and immunity from current expenses, and with the additionl advantage that the propelling power can be relatively increased at the same rate per ton. If, however, the latter advantage were dropped, increased dead weight capacity could be acquired in the iron vessel for about £8 per ton. This appears, nevertheless, to be an entirely fallacious way of looking at the matter. The cost per ton of dead weight capacity should be calculated on the total tonnage, not on the excess. An owner as a carrier has chiefly to consider the total cost of his carrying capacity, and whatever be the unit basis of his calculation, the total cost is the aggregate of the average cost per unit. The question an owner asks himself is, "What will this or that ship cost me per ton of dead weight?" This has been shown to be 4¾ per cent. less in the case of the iron ship than in that of the steel; and as a purely business matter, the fact that a smaller sum is invested for the same net profit would appear to place the iron sailing or steamship, at present, in the more advantageous position as an investment. There is only one condition under which an owner can be placed, where the adoption of steel at its present cost, can be attended with any advantage; and that is where his dimensions are absolutely limited by the conditions of his trade. That condition, however, may be said to exist hardly anywhere in the ordinary carrying trade.

APPENDIX.

Particulars of Steamship taken for Comparison.

Flush deck, with full poop for captain and officers' cabins, bridge house over engine and boiler space, with cabins under for engineers—topgallant forecastle for crew and stokers, iron main deck, wood upper deck, hold beams wide spaced, water ballast in double bottom (McIntyre's plan), in after hold, through engine and boiler space, and 20 ft. into main hold, deep ballast tank to main deck in after hold, class 100 A. Lloyd's, three decks.

AN ACCOUNT OF EXPERIMENTS MADE BY A BOARD OF UNITED STATES NAVAL ENGINEERS WITH SCREW PROPELLERS OF DIFFERENT MATERIAL AND DIMENSIONS APPLIED TO THE UNITED STATES FISH COMMISSION'S STEAMER "LOOKOUT" WITH THE HULL COPPERED AND NOT COPPERED.

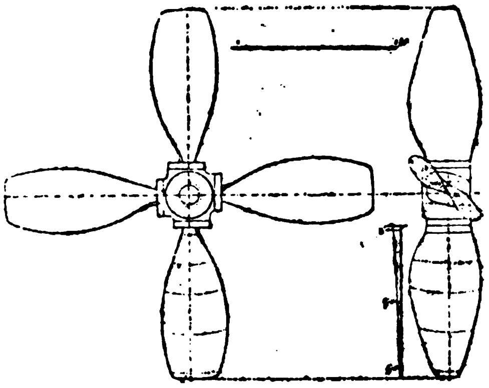
By Chief-Engineer Isherwood, U.S. Navy.

(Continued from page 101.)

THE following are detailed descriptions of each screw, wherein the form of the blade, or its outline, is given, together with its thickness and the diameter of the hub, &c.

Screw *A.*

This screw was of cast brass and had a uniform pitch. The blades, when viewed in projection on a plane parallel with the axis, increased gradually in length from the hub to a radius of 13¼ inches, from which their length gradually decreased to the periphery. The hub was square and the blades—which were cast separately—were bolted to it. The thickness of the blades at the fillet of the hub was 1 1/16 inches.

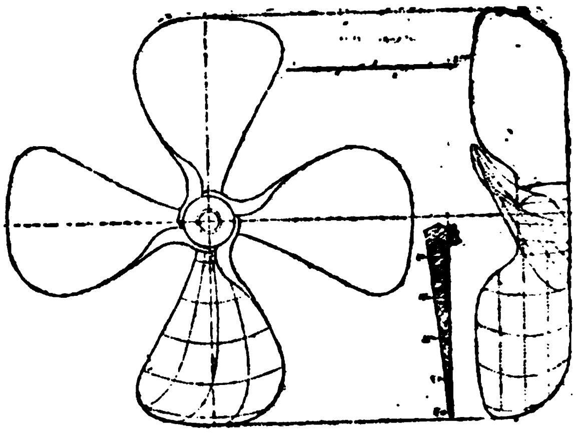


Diameter of the screw	4·6458	feet.
Diameter of the hub	0·8333	feet.
Pitch of the screw	8·4	feet.
Number of blades	4	
Length of the screw at the hub, in the direction of the axis	0·5625	foot.
Length of the screw at radius of 13¼ inches, in the direction of the axis	0·9167	foot.
Length of the screw at the periphery, in the direction of the axis	0·3125	foot.
Mean fraction used of the pitch...	0·3325	
Projected area of the blades on a plane at right angles to the axis	5·4551	sq.ft.
Helicoidal area of the blades	7·9447	sq.ft.

Screw *B.*

This screw was of cast iron, and had a uniform pitch. The hub and blades were cast together. The blades, when viewed in projection on a plane parallel with the axis, had their edges parallel from the hub to a radius of 6½ inches. From this point to a radius of 18 inches the length of the blades gradually but irregularly increased. From the radius of 18 inches to the periphery the length of the blades gradually decreased. The outer corners of the blades were excessively rounded. The hub was cylindrical, and the thickness of the blade at its fillet was 3 inches.

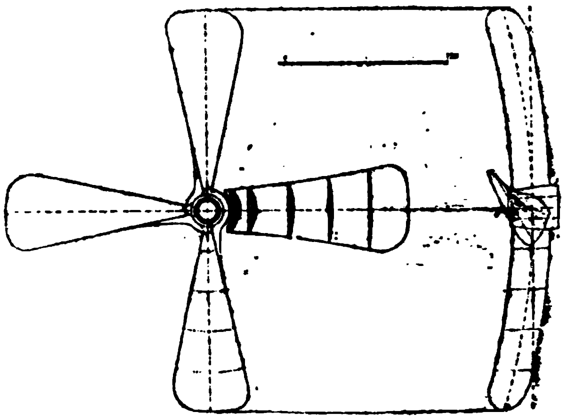
Diameter of the screw	5·00	feet.
Diameter of the hub	0·70	foot.
Pitch of the screw	7·5	feet.
Number of blades	4	
Length of the screw at the hub, and to radius of 6½ inches in the direction of the axis	0·6657	foot.
Length of the screw at radius of 18 inches, in the direction of the axis...	0·5080	foot.
Length of the screw at the periphery, in the direction of the axis	0·5080	foot



Mean fraction used of the pitch...	0·5283	
Projected area of the blades on a plane at right angles to the axis	10·1693	sq.ft.
Helicoidal area of the blades	13·5266	sq.ft.

Screw *C.*

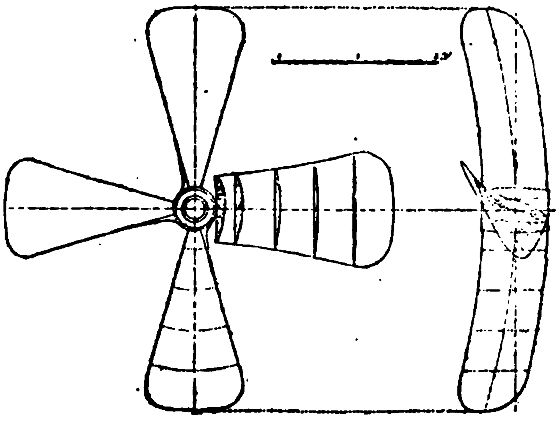
This screw was of cast brass, and had a uniform pitch. The hub and blades were cast together. The edges of the blades, when viewed in projection on a plane parallel with the axis, were parallel segments of circles curving backwards, the radius of the forward edge being 9·25 feet. The outer corners of the blades were rounded with easy curves. The hub was cylindrical, and the thickness of the blade at its fillet was 1¾ inches.



Diameter of the screw	5·0	feet.
Diameter of the hub	0·5417	foot.
Pitch of the screw	7·5	
Number of blades	4	
Length of the screw in the direction of the axis, uniform from hub to periphery	0·5208	foot.
Fraction used of the pitch	0·2703	
Projected area of the blades on a plane at right angles to the axis	5·2457	sq.ft.
Helicoidal area of the blades	6·7860	sq.ft.

Screw *D.*

This screw was of cast brass, and had a uniform pitch. The hub and blades were cast together. The edges of the blades, when viewed in projection on a plane parallel with the axis, were parallel segments of circles curving backwards, the radius of the forward edge being 9·25 feet. The outer corners of the blades were rounded with easy curves. The hub was cylindrical, and the the thickness of the blade at its fillet was 1¾ inches.



Diameter of the screw	5·000 feet.
Diameter of the hub	0·5417 foot.
Pitch of the screw	8·625 feet.
Number of blades	4
Length of the screw in the direction of the axis, uniform from hub to periphery	0·4461 foot.
Fraction used of the pitch	0·1994
Projected area of the blades on a plane at right angles to the axis	3·8697 sq.ft.
Helicoidal area of the blades	5·3470 sq.ft.

Screw *E*.

This screw was of cast brass, and had a uniform pitch. The hub and blades were cast together. The edges of the blades, when viewed in projection on a plane parallel with the axis, were parallel segments of circles, the radius of the forward edge being 9·25 feet. The outer corners of the blades were rounded with easy curves. The hub was cylindrical, and the thickness of the blade at its fillet was 1⅜ inches.

Diameter of the screw	5· feet.
Diameter of the hub	0·5625 foot.
Pitch of the screw	9· feet.
Number of blades	4
Length of the screw in the direction of the axis, from hub to periphery	0·8125 foot.
Fraction used of the pitch	0·3549
Projected area of the blades on a plane at right angles to axis	6·8975 sq.ft.
Helicoidal area of the blades	9·3407 sq.ft.

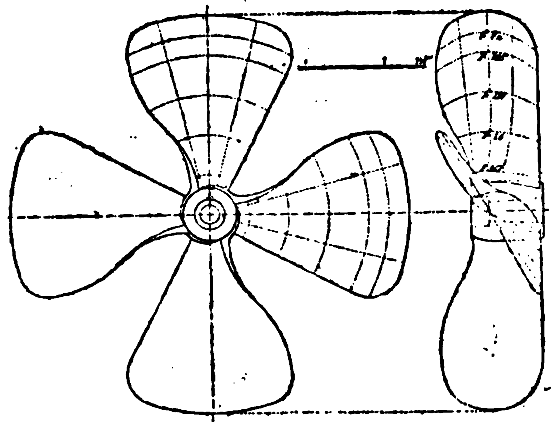
Screw *F*.

This screw was of cast brass, and had a uniform pitch. The hub and blades were cast together. The edges of the blades, when viewed in projection on a plane parallel with the axis, were parallel segments of circles curving backwards, the radius of the forward edge being 9·25 feet. The outer corners of the blades were rounded with easy curves. The hub was cylindrical, and the thickness of the blade at its fillet was 1⅜ inches. In all respects except diameter, screw *F* was the duplicate of screw *E*.

Diameter of the screw	4⅝ feet.
Diameter of the hub	0·5625 foot.
Pitch of the screw	9· feet.
Number of blades	4
Length of the screw in the direction of the axis, from hub to periphery	0·8125 foot.
Fraction used of the pitch	0·3539
Projected area of the blades on a plane at right angles to axis	5·9659 sq.ft.
Helicoidal area of the blades	8·6850 sq.ft.

Screw *G*.

This screw was of cast iron, and had a uniform pitch. The blades, when viewed in projection on a plane parallel with the axis, increased gradually in length from the hub to a radius of 21 inches, from which the length gradually decreased to the periphery. The hub was cylindrical, and the thickness of the blade at its fillet was 4 inches.



Diameter of the screw	5 0 feet.
Diameter of the hub	0·75 foot.
Pitch of the screw	7·9 feet.
Number of blades	4
Length of the screw at the hub, in the direction of the axis	0·8542 foot.
Length of the screw at radius of 21 inches, in the direction of the axis	1·2708 feet.
Length of the screw at the periphery, in the direction of the axis	0·8750 foot.
Mean fraction used of the pitch	0·5736 foot.
Projected area of the blades on a plane at right angles to the axis	11·0098 sq.ft.
Helicoidal area of the blades	14·8453 sq.ft.

EXPERIMENTS.

The experiments were made in the perfectly smooth water of the Potomac River near the City of Washington, over a base of 11⅜ geographical miles, according to the Coast Survey Chart, extending from marks abreast the wharf at Giesborough Point to marks abreast the wharf at Marshall Hall. During all the experiments, the position of the throttle and of the cut-off valves remained the same, nor was there any sensible change in the general state of the machinery. The steam pressure in the boiler was maintained as nearly as possible at 80 pounds per square inch above the atmosphere, and the engine and boiler were managed throughout by the same persons.

Each experiment was made in exactly the same manner. Steam was raised and the machinery operated at the Navy Yard wharf until the fires were brought to steady action, when the vessel proceeded to the nearest terminus of the base, which she passed at her maximum speed for the boiler pressure, when one observer took the time and another the reading of the taffrail log made by Bliss & Co. As the vessel passed the farthest terminus the time and log reading were again taken. The vessel was not put about until at a distance beyond the last terminus that would allow her on the return to pass it at the maximum speed for the boiler pressure, as before. The reading of the engine counter in the engine room was taken simultaneously with the log and time.

The indicators employed were new, and of Thompson's design; during each run, excepting the first four with screw *A*, there were taken by them six sets of indicator diagrams from each end of each cylinder, the diagrams being equispaced over the time. The indicated pressures in the different experiments are the means of all the diagrams taken. During only the last two runs with screw *A* were there any diagrams taken, and the mean pressure from them has been assumed as the mean pressure for the entire experiment.

During all the runs the vessel's trim and draught of water remained sensibly the same.

The experiments with screws A, B, C, D and E consisted of six runs over the base with each, three in each direction, and they were made on three different days, a pair of runs being made in immediate succession on each day. The experiments with screws F and G were made in the same manner, except that they consisted of only four runs over the base, two in each direction, and they were made on two different days, a pair of runs being made in immediate succession on each day.

During experiments A, B, C, D and E the vessel was not coppered, the immersed portion of the hull presenting a planed wooden surface to the water. During experiments F and G this portion was covered with smooth rolled copper.

The speed of the vessel was determined, as stated, by the shore distances and by the taffrail log for each run over the base. The mean of the speeds of the different runs of the same experiment, by the shore marks, is taken as the mean for the entire experiment according to that measurement. And, in the same manner, the mean of the speeds of the different runs of the same experiment by the taffrail log is taken as the mean for the entire experiment according to that measurement. These two measurements differed, and, with a slight irregularity for the different experiments, the mean difference deduced from all the experiments showing, as might be expected, that the indications by the taffrail log were greater than those by the shore marks, the ratio being as 1·0572 to 1·0000. This ratio may be taken as a constant correction for the taffrail log, which, as its determinations were unaffected by current, can be considered, when thus corrected, as the most accurate measure of the vessel's speed. Accordingly, the speed by the log thus corrected is what is given in the following tables.

The mean number of revolutions made by the screw per minute during a run was ascertained from the time and the total number of revolutions given by the counter during that run; and the mean number of revolutions made per minute by the screw during an experiment is the mean of the means of those made during the runs composing that experiment.

(*To be continued.*)

ON THE PROGRESS AND DEVELOPMENT OF THE MARINE ENGINE.*

By MR. F. C. MARSHALL, of Newcastle-on-Tyne.

AT the Liverpool meeting in 1872, Mr. F. J. Bramwell, F.R.S., now Sir Frederick Bramwell, past-president, read a paper before this Institution on "The Progress effected in Economy of Fuel in Steam Navigation, considered in relation to Compound Cylinder Engines, and High Pressure Steam." This paper was most exhaustive in its character, and was followed by a discussion, in which some of our most prominent engineers took part.

Having been asked to prepare a paper for this meeting on the marine engine, the writer naturally turned to what had been laid before the Institution on previous occasions. He found that Sir Frederick Bramwell's paper embraced all the past history and present condition of marine engineering, and to some extent forecast its future. On the same occasion Dr. Siemens, F.R.S., the President for the year, remarked that during the nine years which had elapsed since the first meeting in that city the marine engine had been so far improved, that it consumed rather less than one-half the amount of fuel at that former time thought to be indispensable; and that, if nine years hence his successor were able to announce a similar step in advance, we should have the satisfaction of knowing that the further discussion of the subject that day had not resulted in "lost energy."

We have now completed the term then defined by Dr. Siemens; and the writer proposes to continue the subject from the date of that meeting and endeavour to trace out whether any, and if so what progress has been made; further, to consider whether or no we have reached the finality so strongly deprecated by Sir Frederick Bramwell in the discussion referred to, and if not, then in what direction we are to look for further development.

In his paper Sir Frederick Bramwell gives tables of particulars of the boilers and engines belonging to twenty-eight steamers of different descriptions, and comprising nearly all the types of engine and boiler now in general use. These tables embrace the sizes of cylinders, heating and grate surface of boilers, condensing surface, working pressure, speed of piston, indicated power, and consumption of fuel.

The average consumption of nineteen of these vessels he shows to be 2·11 lb. of coal per indicated horse power per hour. The working pressures range from 45 lb. to 65 lb. per square inch, the latter being the highest pressure recorded, while 376 ft. per minute is the average piston speed.

The writer has been favoured with data, from thoroughly reliable sources, showing in a similar manner the general proportions of engines and boilers recently fitted to steamers in the mercantile marine. These are shown in Table No. I., appended. It will be noted that the steam pressures are now much higher, the boilers have less heating surface, and the cylinders are much smaller for the indicated horse power developed; and at the same time the average consumption of fuel is reduced from 2·11 lb. to 1·828 lb., or by 13.38 per cent.

A substantial progress is thus shown to have been made during the nine years; and although it does not reach the enormous gain of the previous decade, it is probably as much as could reasonably be expected, as the closer we approach the limit the more difficult will improvement become.

The marine engine and boiler of to-day is substantially the same in design and arrangement as Sir Frederick Bramwell described it. The compound two-cylinder vertical engine, with receiver, and with two cranks at right angles, is the most commonly accepted type. It embodies great simplicity in design, great facility—and therefore cheapness—in manufacture; it has few moving parts, is easily handled and tended, is very accessible throughout the working parts while in motion, and is readily repaired.

The single Woolf engine, commonly known as the tandem engine, with single crank and flywheel, as shown in Figs. 3 and 4, was originally introduced and developed by Mr. Alfred Holt, and has recently been adopted by some other shipowners, with great satisfaction to themselves. It is still, however, looked upon with doubt and suspicion as to "unhandiness" by shipowners and their engineers generally, and therefore does not make much progress in numbers as compared with engines having cylinders side by side; and this, notwithstanding the undoubted advantage it possesses, of taking up less fore-and-aft space in the vessel, and of having fewer working parts to be looked after.

Next in order of general acceptance to the two-cylinder receiver engine, with cranks at right angles, is that known as the double tandem engine; which consists of two Woolf engines placed side by side, and working two cranks at right angles, Figs. 5 and 6. These engines have been extensively adopted for the largest Transatlantic steamers, and with great success.

The tandem form of compound engine possesses the great advantage of independence of action, and may therefore be multiplied indefinitely in its application to one propeller. It has long been used in the double form, and last year at Barrow it was introduced to the notice of the institution in its triple form, as applied to the *City of Rome*. So long as it is thought wise to concentrate the propelling power of a vessel in one instrument, the number of such engines working side by side may be increased indefinitely. The triple or quadruple arrangement of such engines, as will readily be seen, gives great uniformity of strain and greatly relieves the weight and friction on the crankshaft, as well as balancing all the moving weights. To set against these facts, there is of course the great disadvantage of increased number of parts, always a serious consideration on board ship at sea.

A modification of the Woolf engine, introduced by Mr. D. Rowan, of Glasgow, about the year 1861, has three cylinders, one high and two low-pressure placed side by side, with piston rods attached to one crosshead. It has recently been very satisfactorily applied to paddle engines of large power by Messrs. Douglas Hebson & W. G. Ramsden, of Liverpool. In this case the steeple form of engine is adopted; the three cylinders of each engine are firmly bolted both to each other, and to keelsons fore and aft the vessel, thus forming a very solid and substantial base from which to work the upper framing. Each set of cylinders is worked by one valve and motion, Marshall's arrangement being used. The three piston rods are attached to the moving crosshead, and guided in the usual way.

The engine, the writer believes, is a novelty as thus applied. It can be made to weigh no more than the oscillating form; it has given most satisfactory economical results in working; it is easy to maintain, and affords great facility of access to all the working parts for overhauling and repair when required.

The most recent form of compound engine, introduced into our

---

Class A—Compound Engines with one High and one Low-pressure vertical Cylinder, working two cranks at right angles.

FIG. 3.

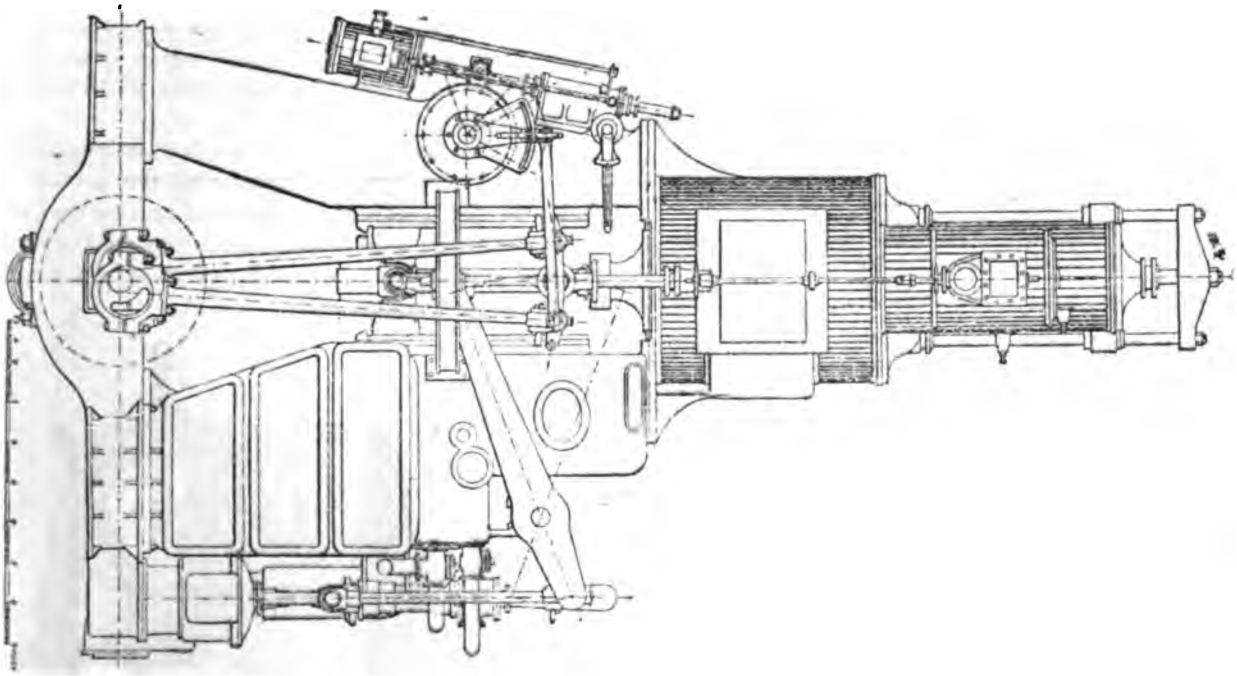

FIG. 4

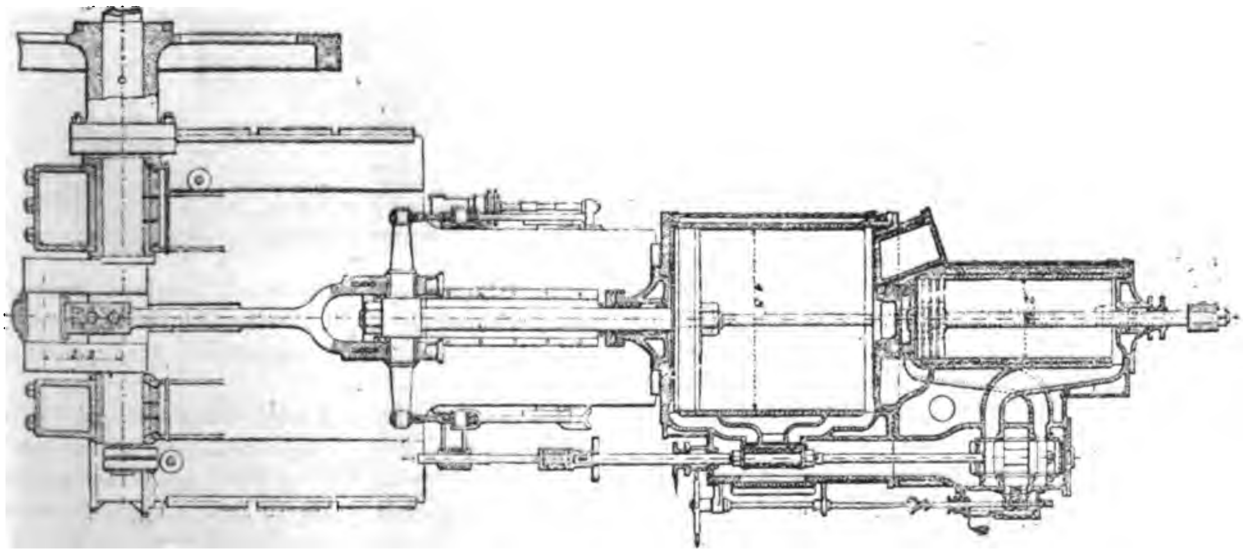


TANDEM COMPOUND MARINE ENGINE.

See Mr. F. C. Marshall's Paper "On the Progress and Development of the Marine Engine," page 128.

Transatlantic steamships, has three cylinders, one high pressure between two low pressure, with an intermediate receiver, and working into one crankshaft, having three cranks placed at equal angles from each other.

This description of engine bids fair to become the favourite one for large powers; several are now at work and give unqualified satisfaction both as to economy of fuel and cheapness of maintenance. The *Arizona*, of the Guion line, one of the first constructed on the plan, has worked so well hitherto that her owners have since ordered others of greater power of the same description. The *Servia* also, now being finished for the Cunard line, has engines of this kind, (Figs. 1 and 2) with cylinders one of 72 in. and two of 100 in. diameter, and 6½ ft. stroke. Compared with the triple tandem engines of the *City of Rome*, these have only half the number of cylinders, pistons, valves, valve rods, and appurtenances to get out of order and keep in repair; while the balance of strains on the main shafting and crank-pins can be readily equalized by the adjustment of the cut-off of steam.

These three great types of compound engines may be placed as follows, in the order of their general acceptance by the shipowning community.

1. The two-cylinder intermediate receiver compound engine, having cranks at right angles.
2. The Woolf engine in the tandem form, having generally the high pressure and low pressure cylinders in line with each other, but occasionally alongside, and always communicating their power to one crank. Such a pair of engines is used sometimes singly (Figs. 3 and 4), oftener two pairs together (Figs 5 and 6), working side by side to cranks at right angles; recently three pairs together, working to cranks placed 120 deg. apart. The system affords the opportunity of adding yet more engines to the same propeller to an indefinite extent.
3. The three-cylinder intermediate receiver compound engine with one high and two low pressure cylinders, the steam passing from the high pressure cylinder into the receiver, and thence into the two low pressure cylinders respectively. The cranks are placed at equal angles apart round the crankshaft, so as to balance the forces exerted upon the shaft.

These three types may be said to embrace all the engines now being manufactured in this country for the propulsion of steam vessels by the screw propeller. In their leading principles they also embrace nearly all paddle engines now being built, whether the cylinders be oscillating, fixed vertically, or inclined to the shaft.

The compound engine in fact, in one of these three forms, may now be said to be universally adopted in this country; and the question of the relative value of simple expansion in one cylinder, and of compound expansion in two or more cylinders, which agitated the minds of some of our leading engineers ten years ago, is now practically solved in favour of the latter.

(*To be continued.*)

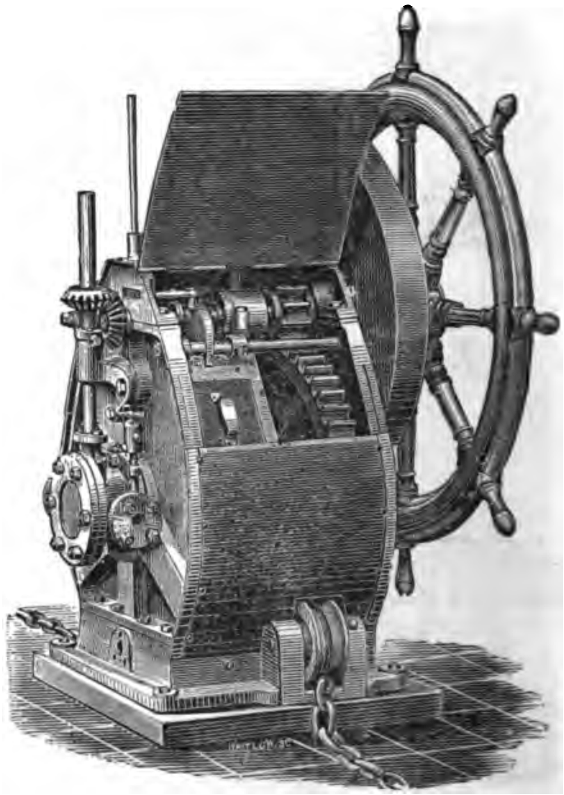
"THE STEAM QUARTER-MASTER."

As the above title implies, the quarter-master's duty is rapidly being usurped by steam, and there is no doubt that in rough and heavy weather the prompt and powerful action of steam steering gear is infinitely more reliable and effective than the sinews of many quarter-masters. The above title has been adopted by Messrs. Higginson & Co., of Liverpool, for their steam steering gear, which has special points of value.

It is arranged for steering by hand as well as by steam,—one motion only (without tools of any kind) being all that is necessary to make the change. Moving a lever, by hand, forward, will make it "hand power,"—moving the lever backward will make it "steam power."

The "Steam Quarter-master" is particularly well adapted for bridge steering, and in a few cases has been planted on the flying bridge itself with the greatest satisfaction: it is considered best, however, to fit the gear for steering from wheel-house and upper bridge as well, which last can be done at small additional cost. Its compactness brings it within range of all who wish for a combination gear (hand and steam), and will go easily into wheel houses already built on running vessels.

The valve connections are worked automatically, and are highly sensitive, regulating the amount of helm to the greatest nicety; and putting the tiller from amidships to hard over in the remarkably short time of 5 seconds, a point of the greatest importance when danger is imminent.



The "Steam Quarter-master" develops immense power without the slightest vibration, on account of all its movements being rotary—no dead points to overcome.

It is finished off with a neat brass-mounted cover, giving it a very presentable appearance, at the same time covering up all working parts, and so reducing to a minimum all risk to life or limb, a most important feature in these days of the Employers' Liability Act.

A "Steam Quarter-master" can be seen any day under steam at the Engineering works of Messrs Smurthwaite, Armstrong, & Co., Gun Lane, Limehouse, London, E.

FIG. 5.

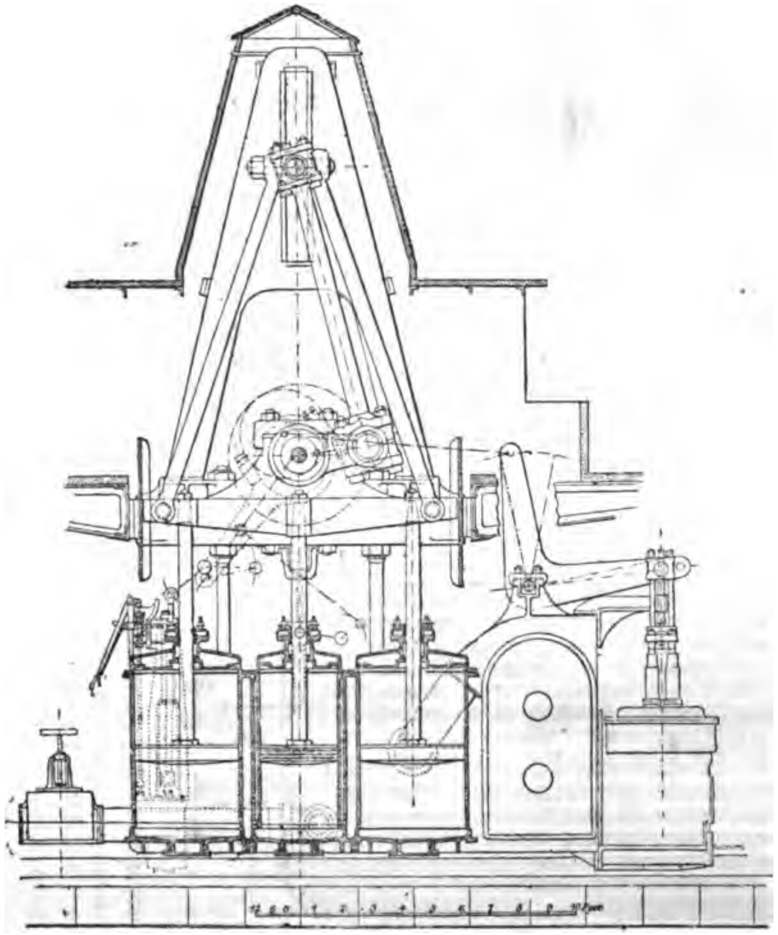


FIG. 6.

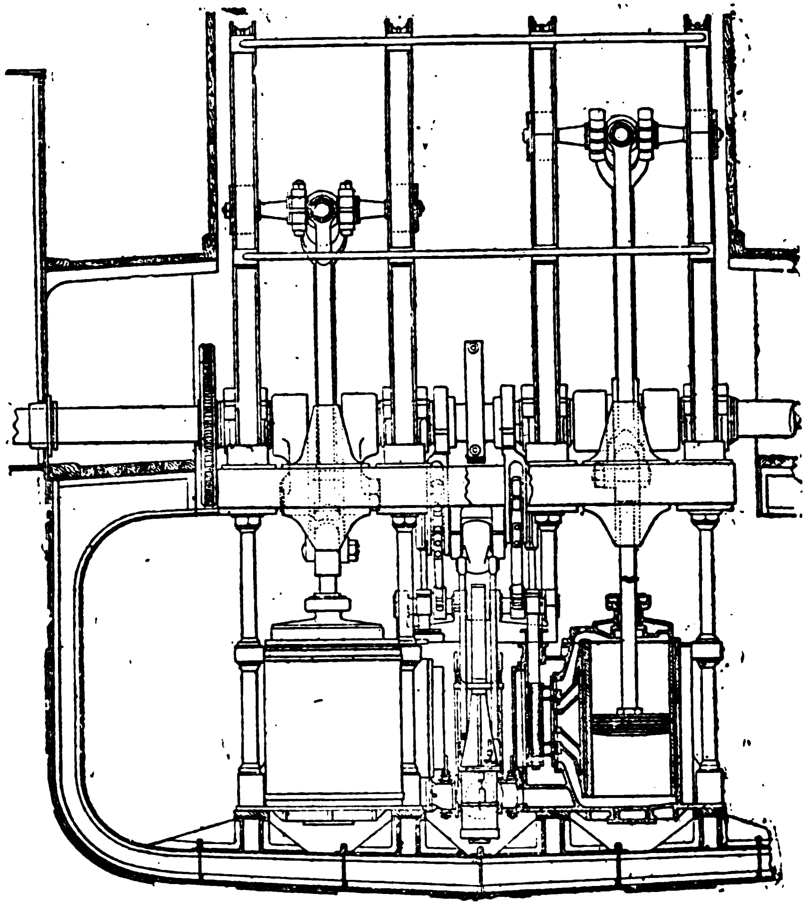


THREE-CYLINDER COMPOUND PADDLE ENGINES.

See Mr. F. C. Marshall's Paper "On the Progress and Development of the Marine Engine," page 128.

Messrs. Higginson & Co., Mersey Street, Liverpool, are the patentees and sole manufacturers, and we are glad to know that their invention has been well patronized since its introduction, now eighteen months ago,—having the seventy-fifth order now in hand in this remarkably short period.

ANTI-CORROSIVE AND ANTI-FOULING COMPOSITIONS FOR SHIPS' BOTTOMS.

THE value of a thoroughly good anti-fouling composition can hardly be over-estimated.

The keen competition which exists at the present day among the various shipping companies to obtain the highest rate of speed, renders everything that helps in that direction of importance to their interests, to say nothing of the benefits to be derived from the diminished cost of repairs, and the prevention of unprofitable delays in dock for cleaning purposes.

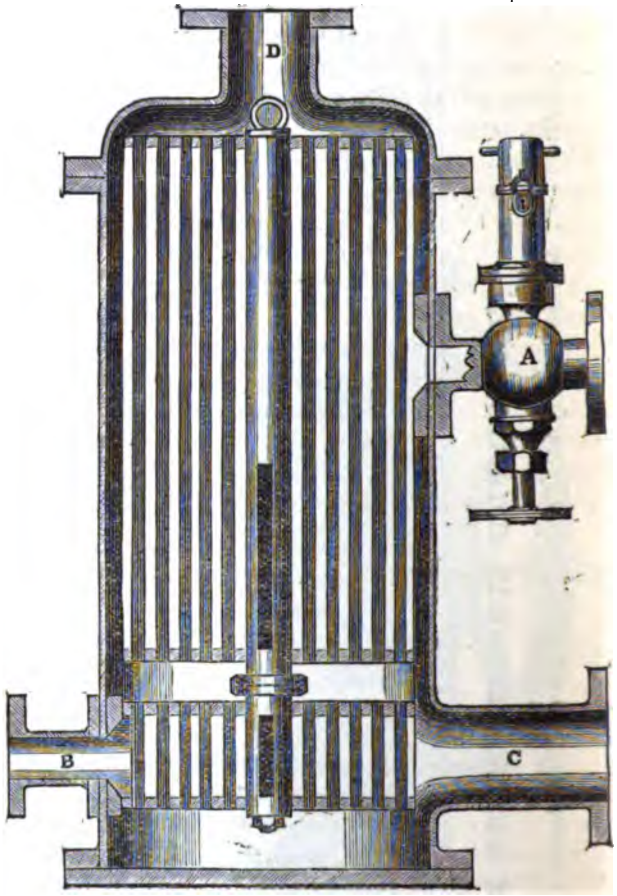
A good practical protective coating for iron ships' bottoms against corrosion and fouling has long been sought after, but few of those brought forward from time to time have been able to stand the test of a long stay in a fouling harbour; others, again, while effective in one particular, have been proved to exercise an injurious action upon the iron plates.

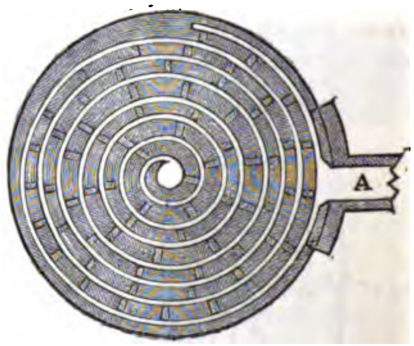
What is really required in a good composition for ships' bottoms is—First, a protective coating which shall be a certain prevention against corrosion in any form, but at the same time not act injuriously itself on the iron plates; and secondly, a coating on which nothing in the shape of animal or vegetable matter can adhere or live.

Since shipowners are at the present time at their wits end to know what to employ on their ships to prevent corrosion and fouling, having tried all sorts of compositions, each of which, as it has been brought out, has had promised for it the desired result, but which, in most instances, has failed in the test. We shall be glad to publish the experience of our practical mariner friends on the subject for their information.

FRESH DISTILLED WATER AT SEA.

IN our last issue we gave a brief notice of a fresh water distilling apparatus, invented by Mr. T. J. Rayner, and of which Messrs. Suffield, Railway Copper Works, Commercial-road, London, E., are the manufacturers. We now append the promised illustrations, viz., a vertical section, and sectional plan of the apparatus. Steam enters at the valve *A*, and spreads from top to bottom of the volute, then travels round till it reaches the centre of the apparatus. The water of condensation passing down, enters the lower volute, becomes quite cold, and then flows out at the pipe *B*. The circulating water enters at the pipe *C*, spreads over the bottom, then passes up through the volutes, and makes its exit through the pipe *D*.





The valve *A* is a combined steam and safety valve; a relief valve is also placed on the cover when required, and so as to conform with the Board of Trade Regulations.

The apparatus is made entirely of copper and gun-metal, and the condensing surface being lined with block tin, there is no possibility of corrosion from salt water as is the case when *iron* is used. Now, for actual *results.* We find that one of the cattle steamers — the *Surrey* —belonging to the Atlantic Transport Co., Limited, was recently supplied with Mr. Rayner's patent distilling apparatus, of a size calculated to produce 4,000 gallons of fresh water per day; and the actual quantity turned out (as per the certificate of the chief engineer) averaged some 1,500 gallons daily in excess of the stipulated supply. Similarly satisfactory results have, we understand, been obtained from the working of the apparatus supplied to the s.s. *Spartan*, and to the steam-yacht *Pandora*. The very small space occupied by this, as compared with any other distilling apparatus, for the same purpose, is a great feature in its favour; for instance, to turn out 600 gallons per day, the size is but 1 ft. 3 in. high, and 6 in. diameter. We understand that Messrs. Suffield have numerous orders on hand for this distilling apparatus, which we have little doubt will receive that extensive patronage which we anticipated for it in our last.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of the* MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Blencowe.—On July 27th, Messrs. G. T. Eltringham launched from their yard at the stone quay, South Shields, a screw steamer, 165 ft. by 26 and by 13 ft., for Messrs. Fisher, Renwick & Co., Newcastle. She was named the *Blencowe.* Her engines are to be put in by Messrs. J. P. Renoldson, and will be 70-horse power.

Bertie.—On July 27th Messrs. M. Pearse & Co. launched from their iron shipbuilding-yard at Stockton-on-Tees an iron screw steamer of the following dimensions, viz.:—Length between perpendiculars, 257 ft. 6 in.; beam, 34 ft. 6 in.; depth of hold to top of floors, 19 ft. 6 in. This vessel is about 1,700 tons gross register, and will carry about 2,350 tons dead weight. She is built for the highest class granted at Lloyd's, with break poop aft, in which is fitted a handsome saloon, with the usual accommodation; has water ballast in cellular bottom, and will be rigged as a two-masted schooner. She will be provided with engines on the direct-acting surface condensing principle of 140-horse power nominal, by Messrs. Blair & Co., of Stockton, four steam winches, and all the most recent and improved appliances for expeditiously loading and discharging cargoes, and for ventilation and other sanitary purposes. As she left the ways, she received the name of *Bertie* from Mrs. Trechmann, of Hartlepool.

Sharon.—On July 27th Messrs. Turnbull & Son launched from Whitehall Dockyard, Whitby, a screw steamer, of the following dimensions:—Length, 240 ft.; breadth, 34 ft.; depth, 17 ft. 9 in.; deadweight capacity, about 1,950 tons. The vessel will be fitted with engines of 130-horse power, by Richardson & Sons, of Hartlepool, and has been built to the order of Messrs. Robinson & Rowland, of Whitby, for the Black Sea trade, and on leaving the ways was named the *Sharon* by Mrs. Rowland.

Gravina.—On July 27th, at the Thames Ironworks, Blackwall, the launch of the royal Spanish cruiser *Gravina* was performed in the presence of a large number of Spaniards resident in England. The Bishop of Avila blessed the ship shortly before it left the dock, and Senora Ocarna then performed the ceremony of christening, and the vessel floated into the dock. The Spanish Government, it appears, has given the order for the building of two powerful corvettes, the first of which, the *Gravina*, is of the following dimensions:—Length, 210 ft.; breadth, 32 ft.; depth, 16½ ft.; burthen, 1,039 tons; armament, three 6-inch (4-ton) breech-loading new type Armstrong guns; and engines of 1,500-horse power. The other vessel, the *Velasco*, is in a forward state, and will probably be launched next month.

Inchrona.—On July 27th a steamer of about 3,400 tons deadweight was launched from Messrs. C. Mitchell & Co.'s yard, Low Walker, for Messrs. Hamilton, Fraser & Co., of Liverpool. She was named the *Inchrona*, is intended for the general trade, and is to be fitted up by Messrs. R. & W. Hawthorn, Newcastle, with engines of about 300 nominal horse-power.

Blagdon.—On 28th July there was launched from the iron shipbuilding yard of Messrs. Hodgson & Soulsby, Cowpen Quay, an iron screw steamer, built to the order of Messrs. Robert Bell & Co., of Blyth. Her dimensions are:—Length, 292 ft.; length between perpendiculars, 285 ft.; breadth, extreme, 36 ft.; depth, moulded, 25 ft. 11½ in.; and depth of hold, 24 ft.; and to carry 3,000 tons dead weight. She will be engined by Messrs. R. & W. Hawthorn, of Newcastle, with engines of about 200 nominal horse-power. She was christened the *Blagdon*, by Miss Bella Bell, daughter of Mr. Robert Bell, the principal owner.

Talley Abbey.—On July 28th Messrs. Irvine & Co., of West Hartlepool, launched an iron screw-steamer, built for the firm of Pyman, Watson & Co., of Cardiff, and designed for the Bilbao trade. She will carry 1,300 tons dead weight, and is 215 ft. in length, her beam being 31 ft. 2 in., and her depth of hold about 15 ft. Her engines are 100-horse power, by Messrs. Thomas Richardson & Sons, of the Middleton Ironworks, Hartlepool; and every appliance, including the cellular principle, has been furnished to render the vessel equal to the highest class. Miss Rosa Lee, of Sedgeley Park, Manchester, performed the christening ceremony, the name given to the steamer being *Talley Abbey*.

Lancaster.—A screw-steamer, named the *Lancaster*, was, on July 30th, launched from the Jarrow yard of Palmer's Shipbuilding and Iron Company (Limited). The vessel is 262 ft. long, 35 ft. broad, and 23½ ft. deep. She will be fitted with a pair of compound surface-condensing engines of 180-horse power nominal. The carrying capacity (deadweight of the steamer, which is intended for the general trade) will be 2,800 tons. She has been built to the order of the Lancaster Steamship Company (Limited), Liverpool, of which Mr. Gilbert M. Steeves is manager, and is the first of a new projected line of steamers.

Pawnee.—A screw-steamer of 950 tons, named the *Pawnee*, was launched on July 30th by Messrs. T. Royden & Sons, Queen's Dock, Liverpool. Her length is 277 ft. 6 in.; breadth, 34 ft. 6 in.; and depth of hold, 25 ft. 4 in. She has been built for the Mediterranean and New York Steam Shipping Company. The *Pawnee*, which is one of three steamers building for the same trade, will be commanded by Captain Clayton.

Regina.—Messrs. Short Brothers launched on July 30th from their yard at Pallion, a screw steamer, built to the order of Messrs. Taylor & Sanderson, of Sunderland, of the following dimensions:—Length over all, 304 ft.; length between perpendiculars, 290 ft.; breadth, 38 ft.; and 29 ft. depth of hold, with a dead weight carrying capacity of 3,100 tons. The vessel has been built on the awning deck principle, to class 100 A 1 at Lloyd's, and has been built under special survey. She was named the *Regina.*

St. David.—On July 30th at the works of Messrs. Walker & Co., at Deptford Green Dock, the screw steamer *St. David*, which has been built for Count Raffo, an Italian Shipowner, and which is intended for the Mediterranean trade, was launched. The dimensions of the ship are:—Length, 150 ft. between perpendiculars; breadth, 20 ft.; and depth 13 ft.; while her draught of water is 10 ft. Her engines are compound service condensing, to indicate 300-horse power, and her speed is 10 knots loaded. The vessel is schooner-rigged, with two pole masts and a complete outfit of fore-and-aft canvas, and is registered 100 A 1 at Lloyd's.

Handel.—On July 30th a large steamer was launched at Messrs. A. Leslie & Co.'s yard, Hebburn, for the Liverpool and Brazil trade. She was named the *Handel*.

Edda.—On August 8th , from the yard of Messrs. S. P. Austin & Son, Wear Dock, Sunderland, was launched an iron screw steamer, built to the order of Messrs. J. T. Salvesen & Co., Grangemouth, and under the superintendence of Mr. D. Marshall, Consulting Engineer, Edinburgh, of the following dimensions :—Length over all, 223 ft. 6 in.; extreme breadth, 31 ft.; depth in hold, 15 ft. 2 in.; gross tonnage, 945; nett tonnage, 634. Constructed with long break, short full poop over cabin, bridge-house, and topgallant forecastle, iron decks, cellular double bottom for water ballast. She will be fitted with compound surface-condensing engines by Mr. John Dickenson, of 100-horse power nominal, steam windlass and steam winches. As she left the ways she was named the *Edda*, by Miss Sybil M. Austin.

Cachapoal.—A large screw steamship, built by Messrs. Laird Brothers to the order of the Compania Sud Americano deVapores, through their London representatives, Messrs. B. F. Smith & Co., was launched from the Birkenhead Ironworks on August 9th, and named the *Cachapoal*, the ceremony of christening being performed by Mrs. G. Smith. The steamer is intended to be employed in the company's service on the west coast of South America; and to meet the special requirements of the trade, and secure protection from tropical heat and perfect ventilation, the sides between main and spar decks have been left open, the spar deck being supported on stanchions, and the whole of the accommodation for first-class passengers and officers provided in deckhouses on that deck under cover of the shade deck. There will be accommodation for eighty first-class passengers. A number of third-class passengers will be provided for on the main deck, and there will be space for a large number of cattle. The *Cachapoal* has a clipper stem with female figurehead, and an elliptic stern, and will be rigged with three pole masts. She is fitted for water ballast, and will be provided with steam windlass, steam steering gear, and five steam winches; also with electric lighting apparatus. Her dimensions are:—Length, 320 ft.; beam, 40 ft.; depth in hold, 21 ft.; tonnage, O.M., 2,519 tons; and she will be fitted with a set of Messrs. Lairds' direct-acting inverted compound engines, having cylinders 45 in. and 80 in. in diameter and 4 ft. 6 in. stroke, supplied with steam at 75 lbs. pressure from four cylindrical boilers, and calculated to develope about 2,000-horse power, and to drive her at a high speed. Among those present were the Earl of Sefton and two of his sons; the Hon. Mr. Crowen; Mr. G. Smith, of London; Mr. Cockburn, Chilian Consul; Professor Wood; Mr. Thomas Drewsbury, the superintending engineer of the company; and a number of ladies and gentlemen.

Carlton Tower.—On August 10th there was launched from Messrs. Wigham Richardson & Co.'s, Neptune-yard, Newcastle, the *Carlton Tower*, a large iron screw-steamer, 300 ft. in length, 37 ft. beam, and 28½ ft. depth, to form one of the "Tower" line of steamers owned by Messrs. Stumour, Weston & Co., of London and Liverpool. As the steamer left the yard she was christened by Mrs. Christie, the wife of one of the builders. Immediately after launching, the *Carlton Tower* was taken under the Neptune sheer-legs to have her machinery put on board, which is of 300-horse power, and of the very latest type. She is fitted with Emerson Walker & Co.'s patent windlass, and will be fitted up in the most complete manner, to suit the American and Eastern trades.

Regent.—On August 10th Messrs. M. Pearse & Co. launched from their yard at Stockton an iron screw steamer of the following dimensions :—Length between perpendiculars, 200 ft.; breadth extreme, 30 ft.; depth of hold, 13 ft. 11 in. This vessel is about 841 tons gross register, and will carry about 1,100 tons deadweight. She is built of the highest class granted at Lloyd's, having break deck and hood aft, in which is fitted a saloon, with the usual accommodation; has water ballast in both holds, and will be rigged as a two-masted schooner. She will be provided with engines on the direct-acting surface condensing principle of 80-horse power nominal from the establishment of Messrs. Blair & Co., two steam winches and appliances for expeditiously loading and discharging cargoes, and for ventilation. As she left the ways she received the name of *Regent* by Mrs. Walker, of Middlesbrough.

Gwalia.—On August 11th, there was launched from the iron shipbuilding-yard of Messrs. Wm. Pickersgill & Sons, Southwick, Sunderland, an iron screw steamer, built to the order of Messrs. Hurley, Matthews, & Co., Cardiff, of the following dimensions :—Length, 240 ft.; breadth, 33 ft.; depth, 18 ft. The vessel has been so constructed as to be suitable for general trades with long quarter deck, bridge over engine and boiler space, cabin amid ships, wheel-house aft, topgallant forecastle, iron decks, cellular double bottom for water ballast the entire length of the vessel. She will be fitted with compound surface condensing engines by the North-Eastern Marine Engineering Company, with 29 in. and 56 in. and 36 in. stroke; also Emerson & Walker's patent windlass. The vessel is expected to carry a total dead weight of 1,900 tons. As she left the ways she was named the *Gwclia.*

Kenmore.—On August 11th an iron screw-steamer was launched from Messrs. Richardson, Duck & Co.'s yard at Stockton. The vessel, which was named the *Kenmore* by Miss W. J. Richardson, of Pott's Hall, is 352 ft. long, 41 ft. broad, and 29 ft. deep. She is 4,000 tons burden, and is classed A 1 at Lloyd's. Messrs. Blair & Co., of Stockton, will supply her with engines of 500-horse power nominal, and Emerson Walker & Co. the patent windlass. The *Kenmore* has been built to the order of Messrs. W. Johnson & Co., of Liverpool.

Lady Dalhousie.—On August 11th an iron screw steamer was launched from the shipbuilding-yard of Messrs. C. Mitchell & Co., Newcastle-on-Tyne. The ceremony of naming her the *Lady Dalhousie* was performed by Miss Mary C. Swan, of North Jesmond. She is brigantine-rigged, and is built to the highest class at Lloyd's, upon the bracket principle throughout, with continuous longitudinal keelsons connecting the outer and inner skins, and has three decks. The vessel is 295 ft. long over all. Her gross register will be about 2,000 tons, and she will be capable of carrying 3,000 tons of deadweight. The engines, which have been made by the Wallsend Slipway and Engineering Company, are of 235-horse power, and will be supplied with steam from two cylindrical multitubular boilers made of Landore Siemens steel, to be constructed for a working pressure of 80 lbs. per square inch. All the modern facilities for despatch in loading and unloading cargo, also in coaling, have been adopted in the vessel, which is supplied with Donkin & Nichol's patent combined hand and steam steering gear. She has been built to the order of Messrs. Adam Hamilton & Co., Greenock.

ON August 11th, there was launched from the yard of Messrs. Raylton Dixon & Co., an iron steamship, which they have built to the order of Messrs. Edward Harris & Co., and which will be, when completed, the largest steamer belonging to the port of Middlesbrough. The vessel is 279 ft. long over all. has a breadth of 37 ft. 3 in., and depth of hold of 24 ft. 6 in., which gives her a carrying capacity of about 3,000 tons dead weight. She will be fitted with engines of 150-horse power nominal, by Messrs. T. Richardson & Sons, of Hartlepool, Emerson Walker & Co.'s patent windlass, and will be in every way completed as a first-class merchant steamer, fitted for the Atlantic or any other ocean trade. This is the eighth vessel which has been built for Messrs. E. Harris and Co. by Messrs. R. Dixon & Co.

Cilurnum.—On August 12th there was launched an iron screw steamer, built for Messrs. Elliott, Lowrey & Dunford, Newcastle, by Messrs. C. S. Swan & Hunter, Wallsend, and of the following dimensions :—Length between perpendiculars, 295 ft.; breadth, 36 ft. 3 in.; depth of hold, 24 ft. 6 in.; tonnage (gross) 2,200 tons. She was named the *Cilurnum* by Miss Fanny Lowrey, and proceeds to St. Peters to receive her machinery of 250-horse power, which has been made by Messrs. R. & W. Hawthorn.

Supply.—An iron screw tank vessel, named the *Supply*, for her Majesty's service, intended for the Bermuda station, was launched on August 12th by Messrs. Laird Brothers. She is of 250 tons load displacement, and will be fitted with a set of vertical compound engines of 120 indicated horse power. She will be provided with powerful steam pumps, to deliver 80 or 100 tons of water per hour, also with steam fire-engines, and with towing appliances; and will, no doubt, prove a very useful vessel on the station.

City of Liverpool.—On August 12th Messrs. Wm. Doxford & Sons, Pallion, Sunderland, launched from their yard a screw steamer, built to the order of Messrs. W. H. Ross & Co., Liverpool. The vessel is 360 ft. long, by 41 ft. broad, and 31 ft. deep. It is intended for the American cargo and cattle trade, and is fitted for spar and main deck, to carry 1,635 head of cattle. Mrs. Hamilton, the wife of Captain Hamilton, the surveyor, christened the vessel the *City of Liverpool* as she left the ways. Her gross tonnage is 3,600 and her engines of 2,000 horse-power, and she is fitted with Emerson, Walker & Co's., Patent Brass Cone Brake Windlass.

Satellite.—On August 13, an addition was made to the Royal Navy by the launch of the screw composite sloop *Satellite*, at Sheerness Dockyard. The vessel has been built from designs prepared by the Naval Board of Construction, and although similar to the ill-fated ship *Doterel*, differs in several important particulars. The *Satellite* is 35 ft. longer and several feet wider in the beam than that ship, her total length being 200 ft. and her extreme breadth 38 ft. The depth in hold is 10 ft. 1½ inches, and height between decks 6 ft. 8 inches. She has a displacement of 1430 tons, being 300 tons more than the *Doterel*, and will carry eight 64-pound guns instead of six, as carried by the other. She is built of iron beams sheathed with teak, and has a steel deck 1½ inches thick for the protection of her engines and machinery, and the hatchways to the engine-room are fitted with shell-proof gratings and shutters, so that the most important part of the vessel will be protected from shell. The coal bunkers are situate below the steel deck between the engine-room and the ship's side, and every facility has been afforded for carrying large quantities of coal. In this respect the *Satellite* has great advantage over other composite vessels and will be able to make long voyages without calling at the different ports for coal. The powder magazines are placed in the fore part of the ship, the space between them being filled with water tanks and chain bickers. The engines of the *Satellite* are being made by Messrs. Humphrey & Tennant.

C. T. B.—On August 13th there was launched from the building-yard of Mr. Wm. Pickard, at Appledore, a schooner of the following dimensions, viz. :—Length of keel and forerake, 83 ft., breadth, 20 6-10 ft.; depth, 9 9-10 ft.; tonnage N.N. 91 tons; builder's measurement, 150 tons. She is named (*pro tem.*) *C. T. B.*, is the property of the builder, and, if not sold, is intended for the Newfoundland and general foreign trade.

Orchomene.—On August 13th Messrs. W. H. Potter & Son launched from their shipbuilding and engineering works, Queen's Dock, Liverpool, a new iron sailing ship of the following dimensions, viz. :—Length, 250 ft.; beam, 37 ft. 9 in.; depth in hold, 23 ft.; tonnage B.M. 1,670 tons, ditto register, 1,550 tons, and of 2,550 tons deadweight capacity. The vessel was launched by Miss Moorecroft, and named the *Orchomene* by Miss Florence Norris. The *Orchomene* is the third of five vessels recently ordered by Messrs. Henry Fernie & Sons from Messrs. W. H. Potter & Son, the remaining two vessels each being of 3,100 tons burthen. The *Orchomene* is built to class 100 A at Lloyd's, and 20 years in red in the Liverpool Underwriter's book, her scantling being in excess of the requirements of both books. She is intended for the East Indian and Australian trades, and will be at once placed on the berth for Sydney. She will be commanded by Captain Findlay.

Isle of Arran.—On August 13th an iron screw steamer was launched from the yard of Messrs. T. and W. Smith, North Shields. The vessel has been built to the order of Messrs. Dixon, Robson & Co., of Newcastle, and is destined for the Spanish and coasting trades. Her dimensions are:—Length, 188 ft.; beam, 29 ft. 2 in.; depth, 13 ft. Her gross tonnage is 700 tons. Her engines, which are to be put in by Messrs. J. P. Rennoldson & Co., South Shields, will be 95-horse power. The vessel will also have the usual appliances for quick loading and despatch of cargo. The vessel was named the *Isle of Arran* by Miss Dixon, Blytheswood, Newcastle.

On August 15th there was launched from the building-yard of Messrs. R. & J. Evans & Co., Liverpool, a screw steamer, for the Steamship Herbert Company (Limited). The vessel has been built to the highest class at Lloyds, and is to carry about 220 tons deadweight, and is intended for the coasting trade. The machinery has been made by Messrs. De Winton & Co., Caernarvon.

Dartmore.—On August 15th Messrs. Richardson, Duck & Co. launched a steamer from their yard at South Stockton. Her dimensions are as follows :—Length over all, 268 ft.; length, b. p., 260 ft.; breadth extreme, 36 ft.; depth in hold, 18 ft. 2½ in.; tonnage, O.M., 1,643 tons. The vessel is classed 20 years in the Liverpool Registry, and has been built under special survey. She is built to the order of Messrs. William Johnson & Co., Liverpool, and was christened the *Dartmore.*

Java.—On August 15th there was launched from the shipbuilding yard of Messrs. Russell & Co., Cartsdyke, an iron sailing barque of 900 tons nett register, and of the following dimensions:—Length, 196 ft.; breadth, 32 ft. 6 in.; and depth of hold, 19 ft. 2 in. She has been built to the order of Messrs. Peter Denniston & Co., Glasgow, and is classed 100 A 1 at Lloyd's. As she left the ways she was named the *Java.*

Morro.—On August 22nd Messrs. Scott & Co., Shipbuilders, Cartsdrke, launched from their shipbuilding yard a twin-screw steamer of about 170 tons register, and of the following dimensions:—Length, 125 ft.; breadth, 23 ft.; depth, 15 ft. 6 in. to awning deck. She has been supplied by the builders with compound surface condensing engines—the diameter of cylinders being 15 and 30 in. respectively, and length of stroke 1 ft. 9 in. She is also furnished with one circular boiler and two corrugated furnaces. The steamer, which has been built to the order of the Pacific Steam Navigation Company, will be employed as a tender for the company's vessels at Panama. As she left the ways she was named the *Morro.* The vessel was taken to the Victoria Harbour to be fitted out and made ready for sea.

Billow.—On August 24 Messrs. Edwd. Withy & Co. launched from Middleton Shipyard, West Hartlepool, an iron screw steamer, built to the order of Messrs. Middleton & Co., of West Hartlepool. Her principal dimensions are :—Length, B.P., 257 ft. 6 in.; beam, extreme, 34 ft. 6 in; depth, moulded, 20 ft. 4½ in.; and deadweight carrying capacity about 2,400 tons. She is built to Lloyd's highest class, and has long quarter deck, bridge-house, and topgallant forecastle, divided into separate berths, with two beds in each; double bottom all fore and aft on the cellular principle; four hatches, arranged to meet the Board of Trade regulations as feeders for grain cargoes; four steam winches, patent windlass, Glover's patent steering gear, and all modern improvements, including Captain Donovan's patent boat lowering apparatus. Her decks, chart-house, engine and cabin skylights, and companions are of iron, and she will be rigged as a topsail schooner. The engines, of 160-horse power, will be supplied by Messrs. T. Richardson & Sons, of Hartlepool, and Patent Windlass by Emerson, Walker & Co., London. She is intended chiefly for the Indian and American trades. As the steamer left the ways she was christened the *Billow* by Mrs. Lawrence G. Bomford, of London.

LAUNCHES.—Scotch.

Thetford.—On July 23rd there was launched from the shipbuilding-yard of Messrs. R. Thompson & Sons, Southwick, an iron screw steamer, built to the order of C. Hutchinson, Esq., Rock Lodge, Roker, of the following dimensions, viz. :—Length, 240 ft.; breadth, 34 ft.; depth of hold, 17 ft. She has been constructed under Lloyd's special survey to class 100 A1, having a long quarter deck, with short full poop containing cabin, bridge house amidships with accommodation for engineers and petty officers, and for firemen and crew in topgallant forecastle. The main bridge, poop, and forecastle decks, together with masts and chart and wheelhouse, are all built of iron. She will be fitted throughout with all the latest improvements, and engines of 130 nominal horse-power, by Mr. George Clark, Southwick. As the vessel left the ways she was christened the *Thetford* by Mrs. Wilson, wife of Captain Wilson, who takes command.

Diamond (s).—On July 26th the *Diamond* (s), built by Mr. W. B. Thompson to the order of Mr. P. M. Duncan, Dundee, was launched from the Caledon Shipyard. This vessel, which has been classed A 1 at Lloyd's, is about 700 tons register, her measurements being—length, 218 ft.; breadth, 30 ft.; and depth of hold, 22½ ft. The steamer is fitted with two iron decks, the upper one sheathed with wood. Being built on the bracket system, with a double bottom extending the whole length of the ship, there is ample provision for water ballast. Compound surface-condensing engines of 120-horse power will be erected, and steam steering gear, steam winches, and all the most improved appliances for working the ship and accelerating the taking in and discharging of cargo will be provided. The christening ceremony was performed by Mrs. James Henderson.

Inisiativa.—On July 26th Messrs. Alexander Stephen & Son launched from their yard at Linthouse an iron screw steamer of about 2,200 tons, named the *Inisiativa*, and classed 100 A 1 at Lloyd's under special survey. This vessel has been built to the order of Carlo Raggio, Esq., of Genoa, and is of the most modern type, embracing all recent improvements, such as a double bottom throughout for water ballast on the cellular principle, steam steering gear, steam winches, and all best appliances for working cargo, &c. The engines and boilers (also made by Messrs. Stephen) were fitted on board before launching. The cylinders are 35 in. and 65 in. diameter by 42 in. stroke, supplied with steam from two ample boilers, having a working pressure of 80 lbs.

St. George.—On July 27th there was launched at Glasgow, from the yard of the London and Glasgow Engineering and Iron Shipbuilding Company (Limited), the pioneer of a new line of channel steamers to ply between that city and London, *via* Littlehampton, and touching at Belfast and Dublin. The line is to be managed in Glasgow by Messrs. Murray Brothers & Co. As the vessel left the ways she was named the *St. George* by Miss Hannah Murray, Myross, Pollokshields. The new vessel is a screw of between 600 and 700 tons, with all the necessary equipments for safety and speed, and has been specially constructed of light draught to suit her for entering the shallow harbour of Littlehampton at all stages of the tide. She is 190 ft. long, 29 ft. broad, and 13 ft. 3 in. deep (moulded); classed A 1 at Lloyd's, and built in accordance with Board of Trade requirements. The *St. George* will form the first of a fleet of four screw steamers now under construction in the same yard; and the second, to be named the *St. Andrew*, is pretty well advanced. She is to be schooner-rigged, and her engines, which are on the compound surface condensing principle, are to be over 100-horse power nominal. In addition to superior cargo space for the conveyance of general goods, the vessels forming the fleet will be able to accommodate a limited number of first-class passengers.

Waverley.—On July 28th the steamer *Waverley*, built by Messrs. Gourlay Brothers & Co. to the order of Messrs. Williamson, Milligan, & Co., Liverpool, was launched from the Camperdown Shipyard, Dundee. The christening ceremony was performed by Mrs. W. O. Dalgeish. The *Waverley* is the second largest steamer which has been built in Dundee, her gross tonnage being 3,080 tons, and her measurements—length, 340 ft.: breadth, 40 ft.; and depth of hold, 26 ft. 10½ in. The vessel has a double bottom, constructed on a longitudinal and bracket system, giving ample provision for water ballast, and she will be fitted with all the most improved appliances. She has been specially built as cargo boat of a superior class, and will be supplied with engines of 320-horse power to enable her to attain a high rate of speed. She is adapted for general trading, and is to be commanded by Alexander Burgess.

Operculum.—On July 30th Messrs. T. B. Seath & Co., the steam yacht builders of Glasgow, launched a small screw steamer, built to the order of Messrs. Luke Thomas & Co., of London, to class 100 A 1 at Lloyd's, special survey, and has been superintended, from the laying of the keel onwards, by her commander, Captain Walter Thomson, of Sunderland. She has been designed and fitted to meet the special requirements of her intended trade, local, &c., at Aden. The vessel was named the *Operculum.*

Christiansund.—On August 6th Messrs. Lobnitz & Co. launched from their shipbuilding yard at Renfrew an iron screw steamer 180 ft. by 25 ft. by 21 ft., 584 tons builders' measurement. She is intended for the trade between Denmark and Norway. The steamer has been built to Veritas highest class, and has been superintended by Captain Moller. The ceremony of naming the vessel *Christiansund* was performed by Mrs. Jack, wife of one of the partners of the builder's firm.

John Burbery.—On August 6th the Campbeltown Shipbuilding Company launched from their yard, French Point, Campbeltown, a screw steamer of about 400 tons. The vessel's dimensions are 145 ft. by 22 ft. by 9ft. 6in. She has been built under special survey, and is classed 100 A 1 at Lloyd's. As the vessel left the ways she was named the *John Burbery* by Miss Nettie Stove, of Lerwick, Shetland. This steamer has been built to the order of Captain Harley, Cardiff, for the coasting trade, and will be engined by Messrs. J. and T. Young, of Ayr.

Mid-Lothian.—On August 8th Messrs. Ramage and Ferguson, shipbuilders, Leith, launched from their yard a steel paddle steamer for the North British Railway Company's ferry goods traffic between Granton and Burntisland. This vessel is capable of carrying a complete train of forty loaded trucks across the Firth of Forth on six feet draught of water. The total length of the steamer is 270 ft., and the breadth 60 ft, while the total deck area is about 13,200 square feet, or nearly one-third of an acre. Compound engines of 600 horse-power nominal are supplied by Messrs. John Kay & Sons, Kirkcaldy. The steel used in the construction of the vessel has been supplied by Mr. Krupp, of Essen, and has been made by the Siemens-Martin process.

Ardgour.—On August 13th there was launched from the shipbuilding-yard of Messrs. Cunliffe and Dunlop, Port-Glasgow, a screw steamer of the following dimensions:—240 ft. by 37 ft. by 17 ft., and of 1,800 tons dead capacity. The steamer, which has been built to the order of Messrs. James Gardiner & Co., Glasgow, is intended for the Black Sea and general trade, and is fitted with water ballast on the cellular system. She is fitted with Bow and M'Lachlan's steam steering gear, Napier's patent steam capstan windlass, and other improvements. Her engines, which are of 130-horse power, will be supplied by the builders. As she left the ways she was named the *Ardgour*, the ceremony being performed by Miss Gardiner, Edinburgh.

Carthage.—On Aug. 24th a steamer named the *Carthage*, built for the Peninsular and Oriental Steam Navigation Company by Messrs. Caird & Co., was launched at Greenock. Her measurements are these:—Length, 430 ft.; breadth, 44 ft.; depth, 35 ft. (moulded); tonnage, 5,100, gross measurement. The ship is a duplicate of the *Rome*, launched by the same builders for the P. & O. Company on May 14th. The large centre-house amidships includes smoking-room and music-room, and from it entrance is got to the main saloon underneath. Forward and aft on each side of the vessel are the state rooms, bath rooms, &c. The vessel is to have a high rate of speed, and with that view very powerful engines are being prepared for her. They consist of four cylinders, having a stroke of 5 ft., with surface condenser, centrifugal and other pumps, &c. The crank shaft, which is in two pieces, weighs 30 tons. Steam will be supplied to the engines by six boilers. These are constructed of steel, and the working pressure will be about 90 lbs. Fuel will be admitted by no fewer than 30 furnaces, and the smoke will be carried away by two funnels. She will be fitted with four masts, and has short poop and forecastle. The best appliances for loading and discharging cargo, for pumping, for extinguishing fire, for steering, &c., will be put on board the *Carthage;* and the engines will have all the most recent patents for starting and reversing, and for controlling them in stormy weather. As the steamer glided into the water, she received her name from Mrs. Sutherland, wife of the chairman and managing director of the Peninsular and Oriental Steamship Company.

LAUNCH.—IRISH.

Coptic.—On August 10th there was witnessed in our harbour one of those interesting events which, by their frequent occurrence, have ceased to be novelties in Belfast—namely, the launch of a huge transatlantic steamship. The vessel which, at a quarter past ten o'clock, glided so gracefully from the slip in the presence of an immense number of spectators was the *Coptic.* She is, we believe, the eleventh of the celebrated vessels that compose the White Star Fleet, all of which were built on the Queen's Island, by Messrs. Harland & Wolff. The *Coptic* is sister ship to the *Arabic*, which on Monday morning left this harbour completely fitted out for sea, and since then has been lying at anchor in our lough, getting her compasses adjusted and having some painting, decoration, &c., executed on board of her. The dimensions of the *Coptic* are:—Length, 435 ft.; beam, 42 ft.; depth of hold, 32 ft.; and tonnage, 4,368. Both these screw steamers are built of steel; and, like the *Arabic*, will be supplied with engines, boilers, &c., rigged, and otherwise fitted out for sea by the eminent firm of builders named above. It may be stated that the engines are 3,000 horse power. Awaiting the launch yesterday morning were a great many persons, on both the Antrim and Down sides of the river. Immediately after the launch the *Coptic* was brought close over to the end of the Queens Quay, adjoining Abercorn Basin, and a numerous staff of workmen soon resumed their operations on board. With all possible dispatch she will be fitted out for sea.

LAUNCH.—FRENCH.

St. Jean.—On August 11th there was launched from the shipbuilding yard of Forges & Chantiers de la Méditerranée at Graville, near Havre, an iron screw steamer built for Messrs. Figueroa Le Roy & Co., and intended for Spanish ore trade. This vessel is the third built by the same firm for these owners. The dimensions are:—Length between perpendiculars, 220 ft.; breadth moulded, 29 ft. 6 in., depth moulded, 16 ft, 9 in.; tonnage gross registered, 1000 tons. She will carry about 1450 tons deadweight, and is classed at the highest class of Bureau Veritas, under special survey. She will be fitted with engines on the compound principle 400 indicated horse power, by the same firm at Havre. This vessel is fitted with double bottom for water ballast, three steam winches and rigged as a two masted schooner, the lower masts are iron. She was christened the *St. Jean*, by Mrs. Doumerc, of Paris.

TRIAL TRIPS.

Uppingham.—The s.s. *Uppingham*, which has been built by Messrs. Raylton Dixon & Co. to the order of E. Pembroke, Esq., Austin Friars, London, left the Middlesbrough dock on Wednesday afternoon, August 10th, for her trial trip. This handsome steamer is built on the spar-decked rule, her length over all being 300 ft., breadth 38 ft. 3 in., depth of hold 26 ft. 2 in. She is built on the new cellular bottom principle for water ballast throughout, has iron main and spar-decks, and latter covered with teak. Her gross tonnage is 2,203, and she will carry 3,530 tons on a draught of 24 ft. The cabins for accommodation of captain and a few passengers are below the spar-deck aft, the entrance to which is protected by a companion-house, and with a hood-aft for the protection of steering gear; officers and engineers are accommodated in 'tween decks amidships. Her engines, which are of 250-horse power, are by Messrs. J. Richardson & Sons, of Hartlepool, and she is fitted with Higginson's patent steam quartermaster and patent direct steam windlass by Emerson, Walker & Co., London, and all the latest improvements for a vessel of this size and class. A small party, consisting of the owner and friends, along with the builder, proceeded with her on her trial trip, which was very satisfactory (11 knots being attained in bad weather), and on the conclusion thereof she proceeded to Cardiff, where she will take a cargo direct for China.

Dalriada.—This screw steamer, lately launched by Messrs. John Fullerton & Co., Paisley, and built to the order of H. H. Smiley, Esq., of Larne, went down the Clyde on her official trial trip on August 20th, under the command of Captain M'Pherson. The *Dalriada* steamed the distance between Cloch and Cumbræ Lights at a speed of over 10 knots an hour, which was considered highly satisfactory by the owners, her carrying capacity being large in comparison with her engine power. The engines, which were supplied by Messrs. William King & Co., Dock Engine Works, Glasgow, worked during the whole trip in a most satisfactory manner.

M. Menatchy.—On August 13th the screw steamer *M. Menatchy*, built for Messrs. Katz Brothers, of Penang and Singapore, by Messrs. Mitchell, Low Walker, proceeded to sea to make her trial of her machinery, which is of 300-horse power, manufactured by the Wallsend Slipway and Engineering Company, and on her run to Newbiggin and back to the Tyne she made an average speed of 13 knots an hour.

Ecuador.—The screw steamer, *Ecuador*, of 1,920 tons, the second of two new vessels just completed by Messrs. Laird Brothers for the Pacific Steam Navigation Company, has made her official trial trip at the mouth of the Mersey, attaining a speed of about 12 knots, the engines indicating about 1,350-horse power.

Dorset.—The steamship *Dcrset*, the latest addition to the fleet of the Great Western Steamship Company (Limited), arrived at Avonmouth after a fine run of 67 hours from the Tyne, a distance of 745 miles. She has on board part of her cargo for New York, and has come to Avonmouth to complete her loading and to receive her passengers. She is a very fine specimen of naval architecture, and is fitted with all modern appliances. Her dimensions are:—Length, 331 ft.; breadth, 39 ft.; depth, 26½ ft. Her signal lights are carried in steel turrets. Her saloon, like the cabins of the *Devon*, *Somerset*, and *Cornwall*, is fitted with Hungarian ash panels, with rosewood mouldings and mahogany styles, but instead of the usual settees has revolving arm-chairs. The builders are Messrs. J. L. Thompson & Sons, of Sunderland. The engines, built by Mr. George Clark, of Sunderland, are massive, and all the parts of unusual strength; they worked during the whole trip with perfect smoothness, and developed a speed of 1,800-horse power. The cylinders are 40 in. and 76 in., with 48 in. stroke. The boilers are of Landore Siemens' steel, fitted with Martin's patent doors, and have been tested to the pressure of 160 lbs. to the square inch. During the passage she ran from the *Longship* light-ship to the one on the Welsh grounds, 160 miles, in 12 hours.

Edith (s.s.)—The screw steamer *Edith*, 900 tons burthen, had her trial trip last month. This vessel was the property of Messrs. Pyle & Co., London, and had been re-fitted and re-classed at Lloyd's by the Strand Slipway Company, and fitted with new engines and boilers by Messrs. Wilson, of the Monk-street Marine Engineering Works, Monkwearmouth. The dimensions of the engines are:—cylinders, 22 in. and 40 in. diameter by 30 in. stroke, with 1,500 feet of heating surface in the boiler, which carries a working pressure of 80 lbs. per square inch, and have been built to the order of the owners, under the inspection of Mr. W. A. Pile, of the firm of Pile & Co. The vessel proceeded as far north as Blyth, and steamed a mean speed of 10 knots, the engines working very smoothly. It is calculated she will steam 8½ knots average speed when loaded with 900 tons, on not exceeding 5½ tons per day of coal. Since the trial the vessel has been sold to Messrs. Powley, Thomas & Co., of Cardiff, this being the third vessel this young and enterprising firm have bought from this locality within a short time. Their previous purchases having been very successful, their shareholders were anxious that they should add another to the number. All parties were well represented: the company on board at the trial trip consisted of Messrs. Powley and Thomas, Mr. Powley and Mr. Pilling from Leeds, and other shareholders; Mr. W. A. Pile, Mr. Powell, engineer, Cardiff, representing the purchasers; Messrs. J. W. and F. Wilson, the engineers; Mr. J. Young, of Shields, and others.

Chateau Leoville.—The trial trip of the *Chateau Leoville*, the fourth steamer completed by the recently established Sunderland Shipbuilding Company, took place lately with results satisfactory to every one connected with the construction or with the ownership of the steamer. The first vessel built by the company was for the Avon Shipping Co., the second for a Liverpool firm, the third for one at Antwerp, and the fourth, the *Chateau Leoville*, for the Bordelaise Steam Shipping Company, which carries passengers and merchandise between Bordeaux and New York. For this trade the *Chateau Leoville* is intended. She is a fine specimen of modern marine architecture, built with flush wooden deck, fitted with three masts, schooner-rigged, and all the latest improvements for the steering of passenger steamers and the loading and unloading of cargo. Her dimensions are:—Length, 380 ft.; breadth, 41 ft.; depth of hold, 31 ft. She is calculated to carry about 4,000 tons, and so provide accommodation for 50 first-class and a number of second-class passengers. At ten o'clock a goodly company of ladies and gentlemen left the New Lock entrance on board the tug *Rescue* to be present at the trial of the engines, which have been built by the North-Eastern Marine Engineering Company (Limited). In a tour round the ship we found the main saloon was reached through a sort of comfortably furnished lounge, and down a flight of wide and well-lighted stairs. The saloon is between fifty and sixty feet in length. It runs to the stern bulkheads, and along its entire length are substantial mahogany dining-tables, with dark crimson velvet covered seatings. On either hand are the berths, likewise fitted with crimson velvet upholstery, and the beds with crimson and gold damask hangings. The partitions between the berths and the saloon are of a design novel to this part of the country. They look both handsome and substantial. The body is of polished walnut, with mahogany panels and rosewood frames. The panels are made diamond-shaped, the lines being about two inches apart, and in the centre of each is a cluster of carefully-carved fruit. The rails are likewise of rosewood, with massive silver-gilt mountings, and between each length is placed a handsome fluted column, in black and gold, with a carved and gilded capital. Near the floor is a row of long narrow ventilating panels of metal work, beautiful in design and colouring; and at the entrance end is the sideboard, a little gem, constructed to harmonize with the panels and other surroundings. The ceiling and other decorative work has been executed by Mr. George Tawse, of Blandford-street, in a renaissance style of architecture. The ceiling of the saloon is panelled and finished in enamel and tints of light blue, light pink and gold, while the panelling beneath the skylight is pleasingly relieved with simple designs in flowers. On the port end of the main saloon is that for the ladies, with bath-room, and sleeping compartments *en suite*, and separate apartments for the maids. The sleeping apartment is fitted with a library, and the berths with blue and gold hangings. The saloon is upholstered in blue velvet, with electro-plated lamp and fittings, the walls being handsomely panelled in harmony with the main saloon. The steward's pantry stands between the ladies' quarters and those of the steward and doctor, the doctor's consulting room, and a row of hot and cold water baths. Above the steward's pantry on deck is a comfortable smoke room, which is reached through the lounging room, the sides of which show a masterpiece of oak graining. The accommodation for the officers and other passengers are on deck amidships, while berths for 44 seamen are provided in the forecastle. The engine-room is exceptionally airy and well-lighted. The engines are 350 nominal horse power, the cylinders being 44 in. by 83 in. with 4 ft. stroke; 80 lbs. pressure, and fitted for variable expansions, and the two boilers are double ended, with six furnaces to each. We may as well here mention that during the trial the engines indicated 1,850-horse power, with 62 revolutions, and that the measured mile off Whitley was run against the wind in 4 min. 15 sec., or at the rate of fully 14 knots an hour. During the afternoon luncheon was served in the main saloon by Mr. W. B. Harrison, of Bridge-street, the arrangements being creditably carried out under the superintendence of Mr. Victor Vivas.

Correspondence.

[It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.—ED.]

"STATUS" OF MARINE ENGINEERS.

To the Editor of the MARINE ENGINEER.

SIR,—I think as a first step to the improvement of our position as suggested by "G. M." and others in these columns, we should put ourselves in communication with the Shipowners' Society and the Board of Trade, for as long as shipowners have to pay tonnage dues for all enclosed places aboard ship, there will be no improvement in the accommodation. For any improvement in wages, the best thing would be to form a Sea-going Engineers Association, having for one of its objects mutual improvement and exchange of ideas.

WAVE.

Sunderland, *August 8th*, 1881.

LAUNCH OF H.M.S. "CANADA."

ON Friday morning, August 26th, the *Canada*, corvette, which had been building at Portsmouth since July, 1879, was launched by the Crown Princess of Germany. The dockyard gates, thanks to the characteristic generosity of Admiral Foley, were thrown open to all comers, a few reserved booths at the bows and starboard side of the ship being alone retained for the privileged classes. The ships in the harbour displayed masthead flags; Royal Standards floated from the dockyard gates, the Semaphore, and the King's Stairs; and amid the bunting with which the dockyard was profusely embellished the Royal flags of England and Germany were conspicuously blended in honour of her who is at once Princess Royal of the one and Crown Princess of the other country, and who is cordially loved by the people of both. In fact, a great surprise awaited the majority of the spectators. Up to Thursday afternoon it was understood that the *Canada* would be launched by the Hon. Mrs. Foley, wife of the Admiral Superintendent of the Dockyard; but as the sister ship, the *Cordelia*, is to be launched in about six weeks' time, it was determined to take advantage of the Crown Princess of Germany's presence in the Isle of Wight to ask Her Imperial Highness to perform the ceremony on the present occasion, a request which was at once graciously complied with. The Princess, with the Princesses Victoria, Sophie, and Margaret of Prussia, and attended by the Countess Kalckreuth, Mdlle. Bussard, Lady Cowley, and Count Seckendorff, left Norris Castle in the Royal yacht *Alberta*, Captain Balliston, at half-past 10, and on arriving at the dockyard the party were driven to the ship, where a reserved space was prepared for them at the stem of the ship. Among the ladies and gentlemen admitted to the enclosure were Prince and Princess Edward of Saxe-Weimar and the principal officers of the district staff, Admiral and Mrs. Foley, Admiral Sir Thomas Pasley, Admiral Chads, Admiral Lethbridge, Captain Sir Michael Culme-Seymour and Lady Seymour, and the Mayor of Portsmouth and Miss Pink. The lanyards which kept the weights poised over the dogshores were led across an ornamental pedestal in front of the Princess, while the customary bottle of wine, concealed in a mass of cut flowers, was suspended over the vicious-looking snout of the ship, the beautifully hollowed entrance of which, moulded as it is, according to the suggestions of the late Mr. Froude, was itself a picture of gracefulness. The *Canada* is scarcely so far advanced as are most ships when launched. In consequence of the state of transition in which naval armaments are at the present time, her gun-ports, alike at the sides and at the fore and after ends, remain to be cut, and her gunnery gear to be placed in position. As, however, the slip was wanted for the laying down of the *Calliope*, and the fittings could be carried out as well in dock as anywhere else, her launching was resolved upon. At half-past 11 the naval church service was read by the Rev. George G. W. Clemenger, chaplain of the yard, after which the hammers of the shipwrights began to play upon the blocks. Ten minutes afterwards Admiral Foley handed the bottle to the Princess, who performed the christening ceremony, by allowing it to dash itself against the prow, and presently afterwards the ship was deemed ready to take the water. The Princess then, by means of an ornamental mallet and chisel severed the lanyards upon the pedestal, and the dogshores were heard to fall with a sullen bang. The corvette, however, did not move at once. A few more blocks were removed, and, after a little persuasion on the part of four hydraulic rams placed under the bows, the *Canada* slid down the ways at a quarter to 12. She is the first vessel constructed at Portsmouth in which steel has been largely introduced, and was built by Mr. W. Malpas, foreman of the yard, under the direction of Mr. J. C. Froyne, the senior constructor, by whom the launching operations were conducted. After the launch the Princess Royal and party lunched with Admiral Foley, and returned to Norris Castle in the *Alberta* at half-past 2 o'clock.

The *Canada* belongs to the *Comus* class of corvettes, which the Admiralty evidently regard as the best form of unarmoured cruisers. There are at the present time no fewer than seven of the kind either in commission or preparing for sea, and of these it may be remarked as significant of their merits that two—the *Cleopatra* and the *Carysfort*—are with the detached squadron under the Earl of Clanwilliam; that two others, the *Curaçoa* and the *Comus*, are upon the China station; and that another, the *Champion*, is in the Pacific. The *Cordelia* is being constructed in the slip adjoining the one from which the *Canada* was launched, while a ninth and tenth, the *Calypso* and the *Calliope*, are about to be laid down at Chatham and Portsmouth. Nor is it difficult to conceive why ships of the class have been received with favour by successive Boards. When it was known that vessels of the *Wampanoag* class were being vigorously constructed in the United States, and that the American Government would probably take advantage, on the first opportunity, of their exclusion from the Declaration of Paris by which the maritime Powers of Europe were bound, and make war, *a la Alabama*, upon the commerce of England, it was generally felt that this country could not afford to allow her unarmoured vedette and patrol fleet to be surpassed by similar cruisers in the American Navy. The *Inconstant* and the *Shah*, frigates, of the length of 337 and 342 feet respectively, and having a load displacement of 5,780 and 6,050 tons, were accordingly built. It would be unjust to state that these ships have turned out failures, for both have performed excellent service in times of emergency, and one, the *Inconstant*, is at this moment the flagship of the Admiral commanding the Detached Squadron. It soon became apparent, however, that they were not exactly suited for the special purpose for which they were designed. As the present Civil Lord of the Admiralty remarked, "The designers were betrayed into an exaggeration of size from over-anxiety to combine in a single ship every quality with which an unarmoured vessel can possibly be endowed. They were to possess unrivalled speed, both under steam and under sail, and to be armed with such batteries of armour-piercing guns that it was hoped engagements might be fought even against armoured ships with some prospect of success. The attempt was ambitious, and not altogether unsuccessful, but they are now found to be too expensive for mere protection of commerce, and their guns would be useless against armoured ships of the present day." Exception may be, and has been, taken to the strictures of Sir Thomas Brassey; but one very significant and incontrovertible fact remains. Since the launch of the *Shah*, no unarmoured cruiser of like bulk has been added to the Navy List. The *Raleigh*, the *Active*, the *Boadicea*, and the *Volage* exhibit a descending scale of length and displacement, until we come to the *Comus*, the last of the series, which only transcends by 260 tons the displacement of the composite corvettes of the *Gem* class. In fact, the Constructive Department have differentiated the purposes of our men-of-war, and have abandoned the hopeless attempt to construct a perfect and universal ship. In the *Iris*, which is distinctively termed a "despatch vessel," everything has been sacrificed to speed, while the *Nelson* and the *Northampton* have been specially designated by the Controller of the Navy as examples of what he calls "our protecting or armour-clad cruisers," the business of which is not to take part in a close engagement, but "to roam over the seas and drive away those wasps, those unarmoured fast cruisers, which were to be brought to bear upon us by stopping our trade and preventing us carrying on that commerce in which we have always taken the foremost place all over the world."

As handy unarmoured cruisers, which can dispense with docking because of their coppered bottoms, and with steam and coal depôts to a very large extent, because of their enormous sail capacity, and which, consequently, may be employed as patrols and escorts upon distant stations, no class of vessels surpasses the corvettes of the *Comus* class; and of these the *Canada* may be regarded as the most efficient, since she combines within herself all the latest improvements and developments. Instead of the auxiliary stern rudder with which the *Comus* was fitted under the shaft, the *Canada* has been provided with a bow rudder, for use in case of the main rudder, which is made of wood, with iron shields, being carried away. The arrangement of this rudder, which is, however, merely experimental, and will not be fitted to the *Cordelia* until it has been tried at sea, is somewhat peculiar. It is placed in the centre line of the ship, just abaft the stem, or what is technically called the fore deadwood. When required, it is made to lower below the keel, and to be drawn up within a well when not needed; but, should the ship be driven into shallow water, and injury be likely to accrue from there being no time to hoist the rudder into the well, it is so adjusted that it can be instantly dropped into the sea. Another improvement has reference to the propeller. The other ships of the class are provided with a screw well, into which the propeller can be lifted when the ship is under canvas; but in the *Canada* the resistance of the screw in similar circumstances can be reduced to a *minimum* without the trouble of disconnecting it. The screw is simply turned so that the two blades are brought in a vertical position parallel with the sternpost, when, by means of Mr. Bevis's patent gear, which is worked from inside the ship, the blades are feathered and placed in a fore and aft direction. The armament of the *Canada* also differs from her sister ships. Instead of 14 guns, consisting of 7-inch and 64-pounders, she will carry 10 of the new 6-inch B.L.R. guns. She will also be fitted with gear for ejecting the Whitehead torpedo, ports being cut through on each side of the lower deck, in addition to a defensive armament comprising two Nordenfeldt guns, capable of being fired from six positions, a couple of Gatling guns, one 9 pounder field-gun, and a 7-pounder boat gun. In most other respects the *Canada* closely resembles the corvettes of her class. She measures 225 ft. between perpendiculars, 44 ft. 6 in. in extreme breadth, and 21 ft. 6 in. in depth of hold. Her estimated load draught forward is 17 ft., and aft 18 ft. 6 in., while her total displacement when fully equipped for sea is 2,383 tons. Her officers and crew will number 245, and while the normal quantity of coal which she will carry is 270 tons, she will be able, in case of pressing necessity, to stow as much as 370 tons. The transverse frames are formed of iron, but the rest of the material, such as the skin plating, transverse and other bulkheads, longitudinals, &c., are steel. The stern and body posts and ram are composed of solid brass forgings, while the rudder is made of oak. A novel feature in ships of this class is the 1½ in. steel shell-proof deck, which is placed 3 ft. 6 in. below the water-line, and extends over the whole length of the engines, boilers, and magazines, side plating, seven-eighths of an inch thick, being also fitted in wake of the deck and water-line. From the shell-proof deck up to the lower deck water-tight cellular spaces are fitted, so that, in the event of one being pierced by shell, the others will remain intact, and thus preserve the buoyancy of the ship. The spaces at the side are intended to be filled with coal, while the others will be appropriated to patent fuel or stores. This arrangement not only affords protection against shot, but localizes to a single, small compartment any leak arising from shells penetrating the side. Upper and lower coal bunkers are provided, and, as the latter may be emptied without interfering with the former, a strake of coal armour can be allowed to remain as long as possible in the neighbourhood of the water-line. Coffer dams are erected round the large hatchways to the engine-room, boilers, and stoke-holes, while the hatches themselves are protected by armour-shutters or bars, the result being that the spaces below are supposed to be completely protected from shell fire. The steel skin of the ship is cased in two thicknesses of wooden sheathing, upon which the copper is fastened. The engines, of which the propeller-shaft and the after part of the crank-shaft are already in place, are by Messrs. J. & G. Rennie, of London. They are to be of 2,300 indicated horse power, and are of the horizontal compound type, having four cylinders, each high-pressure cylinder being at the back of and working in conjunction with its respective low-pressure cylinder. Two of the cylinders are 36 in. in diameter, while the others are 64 in., the stroke being 2 ft. 6 in. Steam will be supplied by six boilers, having a heating surface of about 6,600 square feet. The general arrangement is in other respects very similar to that in the *Bacchante* and *Boadicea*, by the same makers. The funnels will be made to lower, a new feature in this class of vessel.

Notes and Novelties.

A WOODEN ship has recently been built and launched at Blyth—a rare circumstance. Iron ships now rule the market, and a wooden ship being built is now quite a curiosity.

A SEA MESSENGER.—During the recent cruise of the Reserve Squadron, a sea messenger, invented by Mr. Julius Vandenbergh, of Portsmouth, was tried, by order of the Duke of Edinburgh, Admiral Superintendent of Naval Reserve. The "messenger" consists of a vessel, pointed at each end, 3 ft. 6 in. in length, made of copper, and lined with cork and composition, to resist external pressure. The inner case will carry a weight of 60 lbs. The messenger was thrown over from the *Hercules* flagship in lat. 56 49 N., long. 41 E., on July 24th. It was picked up on August 18th by a fisherman, off Hanstholmen (Jutland), and although it had been 25 days in the water, and had travelled about 1,420 miles, it was quite uninjured. It was taken to the British Vice-Consul, and on being opened, was found to contain a number of letters for England, which were at once posted, together with the following message, bearing the signature of the Duke of Edinburgh:—"This message is put overboard from Her Majesty's ship *Hercules*, flagship of First Reserve Squadron, bound from Kiel to Leith, as an experiment at the request of the inventor, and not on account of any accident or disaster. Messenger launched at 11.30 p.m.; all well, weather fine, sea smooth, wind S.S.W., force 3. The finder is requested to deliver the messenger and paper to Lloyd's Agent or the British Consul, and to note the date picked up, and the latitude and longitude of the place where found.—ALFRED, Rear Admiral."

HERRESHOFF & WHITE'S PINNACE.—An exhaustive series of comparative trials, extending over three days, has lately been made by the steam departments at Portsmouth Dockyard with a Herreshoff and a White's 48 ft. pinnace. The Herreshoff is worked on the inventor's coil boiler principle, and has both the engine-room and the stokehold enclosed, forced air being used at a pressure of 2 in. as measured by the water gauge. White's, on the other hand, is an ordinary service pinnace, having only the stokehold enclosed, and is propelled by twin screws. As the result of six runs on the measured mile in Stoke's Bay, the Herreshoff realized a mean speed of 15·124 knots, and White's a speed of 12·604 knots an hour. No diagrams were taken, as Mr. Herreshoff objected to their being taken with a closed engine-room, so that the horse-power developed was not ascertained. The vessels were also tested with respect to the economical consumption of fuel. Each pinnace took on board 10 cwt. of coal, and having proceeded to the westernmost measured mile buoy, were kept running at full power until the engines stopped for want of steam on the consumption of the coal. The Herreshoff went 28 times round the buoys before its fuel was exhausted, while Mr. White's boat, after going 29 times round the buoys, proceeded into harbour, having 258 lbs. of coal unconsumed at the end of the trial.

WOODEN VEDETTE TORPEDO BOATS.—The two wooden vedette torpedo boats which Mr. Trevelyan stated had been purchased in America at a cost of £2,500 each, would appear to have been bought somewhat at random, and without sufficient care as to their satisfying the usual requirements previous to being accepted. They are built of yellow pine, and though they resemble in length and beam the ordinary service pinnaces, they are considerably lighter in the water, and are wanting in the air chambers which convert the English-built pinnaces into lifeboats. On being tested at Portsmouth against a pinnace built by Mr. T. White, of East Cowes, they were found to realize a higher rate of speed, but with a greater consumption of fuel, and a considerable loss of stiffness, and as several improvements have been since introduced into 48ft. pinnaces, it was proposed by the officers at Portsmouth to try the American craft against a new White pinnace which has been supplied to the *Inflexible*, and which from its remarkable handiness has been called the Turnabout. This competition was accepted by the American builder, but eventually declined, on the ground that he did not stipulate for a manœuvring trial. A day was fixed by the Portsmouth officers for the English and the American pinnaces to be inclined for the ascertainment of their respective stabilities, and they were accordingly placed in the mast pond for the purpose. A certain amount of iron ballast was placed in the stokehole to represent the coal, while other quantities were disposed in various parts of the craft to represent the weight of the torpedo gear and other fittings. The Americans, however, objected to this arrangement; they insisted upon the ballast being placed in the main cabin and along the keelson, and as the constructors would not agree to a test which would be of no practical value, the ballast was all withdrawn. The builders contend that stability forms no part of the conditions, and as the stipulated speed has been more than realized, the Admiralty will have to accept the pinnaces as they are.

AN ARGENTINE IRONCLAD.—The *Almirante Brown* left her moorings at Greenhithe on August 16th, and steamed past the Nore for gun practice. Her armament consists of eight 8-in. 11½-ton breech-loading Armstrong guns of the new type, firing projectiles of 180 lb. weight, with 90 lb. battering charges. There are besides six new type 40-pounder breech-loading guns on automatic carriages together with smaller guns. A couple of rounds were fired from each of the guns in the course of the practice. Although the battering charges of the guns are twice as large as those of the guns of similar weight in the British and other services, no injurious results of any kind were observed in any part of the structure or fittings of the ship, or in the carriages or appliances of the guns. The *Almirante Brown* returned the same afternoon to Gravesend, and is expected to leave for South America in a few days. It will be remembered that this vessel has been constructed by Messrs. Samuda, at Poplar, the armament being arranged and supplied by the Elswick firm. She is built entirely of steel, is of 4,200 tons displacement, and 4,500 indicated horse-power. In her trial trips on June 14th she attained an average speed on six runs of over 14 knots an hour. Her eight 8 in. guns are so mounted that three of them can be fired straight ahead, three straight astern, and three on each broadside. The gun has penetrated, at Shoeburyness, an unbacked, solid wrought iron armour-plate of 16 in. thickness, and is, therefore, competent to pierce the great majority of ironclads. In range it exceeds all the guns as yet mounted in the British Navy, and in penetrative power surpasses all but the guns of the *Inflexible*, *Dreadnought*, *Devastation*, and *Thunderer*, which vessels carry only four guns each. It has been, together with the 6 in. 4 ton gun, very exhaustively tested by a mixed War Office and Admiralty Committee. The Admiralty have ordered the *Rover* to be armed with twelve of the 6 in. 4 ton Armstrong guns, in place of the existing armament, and have ordered 103 similar guns to be made at Woolwich, so as to carry further such substitution. But no step has been as yet taken towards replacing the existing 12 ton guns of the Navy with the new type 8 in. guns. This gun became famous in the Chilian war, and the Chilians are now re-arming their navy (including Sir E. Reed's ironclads and the well-known *Huascar*) with it, and larger guns of the same type.

AUSTRIAN TORPEDO BOATS.—The trial of the first of two sea-going torpedo boats built for the Austrian Government by Messrs. Yarrow & Co., of Poplar, took place lately, and resulted in perfect success. The run took place over the measured mile at Long Reach, and was attended by Count Cassini, the Austrian Naval Attaché, and the chief officials of the constructive and engineering departments at Pola. The vessel is of the Batoum type, but in many respects is an improvement upon that vessel, which was built for the Russian Government by the same firm last year. She is steel built throughout, her dimensions being, length 100 ft., beam 12 ft. 6 in., and depth 6 ft. 6 in., which give a thoroughly sea-going craft, and one capable of holding sufficient fuel for a run of from 800 to 1,000 miles at a ten-knot speed. Her engines are on the compound principle, the high-pressure cylinder being 12½ in. and the low-pressure 21¼ in. in diameter, with a stroke of 16 in. The boilers are of the locomotive type, with 922 square feet of heating surface. She is propelled by a single screw, having a diameter of 5 ft. and a pitch of 6 ft. 6 in. She is steered from a conning tower placed forward, and has two rudders, one a balanced rudder forward, and the other aft, which is of the ordinary form. She will be fitted with steam steering gear. Her engines are placed forward, and her boilers aft, and she has a closed stokehole, air being drawn from the engine room, to which it is admitted by a series of small air syphons, instead of one large ventilator, as in ordinary practice. This is one improvement which has been introduced, while another is the addition of means for working the engines at high pressure should the condenser get pierced. If a leak should occur, ample pumping power is provided to cope with it, as there is a 2-inch hand pump, a 3-inch steam pump, and the 4-inch circulating pump of the engines available. This vessel will fire two Whitehead torpedoes, and another improvement introduced by Messrs. Yarrow is the disposition of the torpedo tubes. Formerly they opened out from the bows, one on either side. They are now completely encased, and provision is made at the bow of the boat for a man to go down and obtain access to the front end of the tubes. According to the terms of their contract, the builders were to obtain a speed of 20½ knots per hour, but the result of the trial yesterday was a speed of 22·1 knots. The engines are of 550 horse power indicated, and this was obtained on the trial run with a steam pressure of 112 lbs. per square inch, and 440 revolutions per minute. It is to be observed that the trial was not made with the vessel light, but with 20 persons on board and 2½ tons of coal, which is sufficient to carry her a 300-miles run.

A PATENT CUTTER.—The Admiralty are so well satisfied with the handiness and performances of the 25 ft. cutter which has been built for the Navy by Mr. J. Samuel White, of East Cowes, with the after deadwood cut away, that they have proposed to construct a corvette on the same principle at Chatham. But in order that the sailing qualities of the patent cutter might be tested against an ordinary cutter of similar size and form, as it was thought that a large amount of weather helm would be required in the new craft to keep her head to windward, Lieut. Scullard and Lieut. Pelly were deputed to make the comparative trials. The trials have just been completed in the Solent, and have demonstrated that the superior manœuvring powers of the patent cutter have entailed no loss of steadiness or seaworthiness. The new cutter was precisely the same as the one which has been supplied to the *Inflexible*, the only difference being that it is fitted with a two-bladed, instead of a four-bladed propeller, so that the blades, when not under steam, might be allowed to remain vertically in the water, and thus present no resistance to the way of the boat when under sail. The vessel is steered by means of two rudders, the after one being stepped upon a shoe, and both are worked by the same tiller, which is fitted with a sprocket wheel and chain arrangement. The sail power, which is considerable, consists of mainsail, foresail, and mizzen, with a lateen rig. The two cutters were first tried with the after deadwood attached, and the sailing qualities of each having been ascertained to be about the same under all conditions of wind, the deadwood of the patent craft was then disconnected, and the two were afterwards tried in competitions on and off a wind. With the wind astern there was practically no difference in their respective performances, but in tacking to windward the patent cutter ran away from its service rival, going about in from 20 to 22 seconds, or half the time required by the other. The moment the helm was put down she came up to the wind. Contrary to what was expected on the part of the naval authorities, no weather helm was needed to keep the patent cutter to the wind, the tiller being kept amidships. In a larger vessel, however, it was held to be desirable to remove the centre of effort forward by advancing the mainmast about 3 ft.

THE "NELSON."—The *Nelson*, armour-clad, Captain Erskine, arrived at Spithead at the end of her week's cruise for the trial of her machinery, previous to sailing for the Australian station. She was inspected at Chatham by Admiral Macdonald, and started for her cruise in the Channel. Soon after leaving, a serious leak was discovered in the port high-pressure cylinder cover, and as a rejointing was necessary, as well as a readjustment of the crank-bearings, the *Nelson* put into Portland. She continued her trial, and was again compelled to put into Portland through stress of whether. In the meantime, a series of seven trials were made under various conditions of steaming, the engines and boilers working very satisfactorily, the latter yielding sufficient steam during the six hours of full-power trial without having recourse to the blast. Water, however, was required upon the crank-bearings to keep them cool, and some readjustments will be necessary before the ship leaves Portsmouth. The following *maximum* results were obtained:—With four boilers working, the revolutions were 47, the horse-power 1,783·65, the mean speed 6·95 knots, the consumption per unit of horse-power per hour, 1·7 lb.; with six boilers the results were:—revolutions, 63½, horse-power, 3,067·01, mean speed 10·6 knots, and consumption 1·9lb.; while, with all the ten boilers lighted and the engines going at full power for six hours, the results were as under:—revolutions 80, horse-power 6,219·14, mean speed 13·33 knots, and consumption 2·2lb. The whole of the results were realized without the use of the blast, the object being to work the engines as economically as possible. The complement of stokers on board is greatly below the requirements of the case, and a dozen of seamen were required to trim coal. The ship contains two stokeholes and two engine-rooms, and no fewer than 30 furnaces, yet the total number of stokers does not exceed 44. Besides attending to the fires, the men of this rating are employed in oiling the machinery when under way, cleaning and polishing it when at rest, sweeping tubes, and making themselves generally useful. The 44 are divided into three watches of four hours each; but the experience of the experimental cruise has proved that they are barely sufficient for two watches. The complement will probably be increased before the *Nelson* leaves Spithead, although the scarcity of this particular rating is becoming a grave inconvenience in the service.

THE Admiralty have just approved of an estimate for the building, at Portsmouth, of the *Imperieuse*, an armour-plated steel cruiser, which will not resemble any vessel afloat. The cost of her hull alone will be £325,000. Her load displacement will be 7400 tons, and her length 315 ft., with a beam of 61 ft. She will be built with four barbette turrets, and have an outer casing of wood, the barbette being armed with 18-ton breech-loading guns, having a "disappearance arrangement." Her engines will be 8000-horse power.

DURING the presence of the British Squadron at Kiel, an inspection was made by several of the engineers of a hydromotor vessel recently constructed there from the designs of Dr. Fleischer, of Dresden. In this vessel the usual ship's engines, worked by means of wheel or screw, are replaced by hydraulic reaction, by the drawing in and ejection of a stream of water. The great and novel feature of Dr. Fleischer's application of this principle is the immediate operation of the steam power upon the water, without any loss of such power in conveyance from steam engines and pumps. While the new hydromotor allows of as much as 90 per cent. of the indicated steam power being applied to the production of the outflowing water stream, not more than 30 per cent. has been secured with the reaction machines hitherto constructed. By the new invention the manœuvring capabilities of the vessel are also greatly increased. The usual complicated machinery is replaced by a remarkably simple contrivance, which cannot easily get out of order. The professional gentlemen who took part in a short trip with the hydromotor, at the request of the Duke of Edinburgh, expressed the most unqualified appreciation of the invention of Dr. Fleischer, and of every detail of its execution. The easy manœuvring of the vessel, the comparatively insignificant consumption of coal, and the practicability of adapting the system to all rates of speed were clearly manifested, and the simplicity of construction was regarded as particularly valuable for warships. It has been arranged that the hydromotor shall be sent to England for further testing.

Recent Applications for Patents connected with Marine Engineering, Ship Construction, and Mechanical Appliances for use in Ships, from 19th July, to 22nd August, 1881.

3135. W. Morrison and C. Norfolk. Screw propellers.
3175. A. Figge, G. A. Kottgen, and H. Wedekind. Steering and propelling.
3181. F. C. Glaser (communicated by H. Heine). Water tube boilers.
3182. P. F. Dundon. Boiler furnaces.
3186. M. Havelock. Speed governors.
3193. G. L. Lambert. Valve gear.

3611. T. Hancock. Sorting and loading coal.
3634. H. Garland. Grain elevator.
3642. F. Nash. Fire bars.
3647. J. Walker and W. & T. Thompson. Steering apparatus.

⁂ Any information regarding these or other patents will be gladly furnished on application.

AT Newport (U.S.) the second official trial of a new submarine torpedo-boat was made before several army and navy officers. It was directed from the shore by an electric current, and the adjustable switch on board worked perfectly. It went half a mile in 2 minutes 53 seconds, was made to stop and start at will, go to port and starboard, and brought back to the starting point. The trial is said to have been a success in everything except speed, which was little more than 10 knots an hour, instead of 13, as the inventors claimed. At the third trial the time was 2 minutes 42 seconds.

NEW DOCK AT DUMBARTON.—A squad of workmen have commenced to construct a new dock in connection with the Leven shipyard, belonging to Messrs. William Denny & Brothers, Shipbuilders, Dumbarton. The new dock is almost immediately under the shadow of Dumbarton Castle, and sheltered from the wind in every direction. It will extend from the mouth of the River Leven, run across the grounds of Castle Green, and extend on to the Castle-road and beyond a distance of about 120 ft. The extreme length of the dock on the side next the Castle will be 920 ft., and on the side next the Leven shipyard 650 ft. The breadth of water surface in the dock at high water will be 230 ft., and the extreme breadth of the dock to the edges will be 250 ft. On the side of the dock next the Castle there are to be a pair of iron shear-legs capable of lifting 100 tons at one lift, and of such a height and overhang as to be capable of putting this weight on board the largest and broadest of vessels. As at present arranged, the draught of water in the dock at ordinary spring tides is to be 20 ft., but the dock is so arranged that it can be deepened ultimately to 25 ft.

TRIAL OF THE LARGEST DREDGER IN THE WORLD.—On July 15th the new iron hopper dredger recently constructed by Messrs. W. Simons & Co., Renfrew, for Otago, was tried on the Clyde, and dredged at the rate of 400 tons per hour, which was plunged into its own hold or hopper cavity, capable of containing 1,300 tons of spoil. At the same time it loaded with several hundred tons the new Government steamer *Perseverance*, which came alongside. Afterwards, by steam appliances, its bucket girder was elevated, and its twin screw propellers put in motion, and the vessel steamed away down the Clyde to the measured mile, where the loaded speed was tested at 7½ knots per hour; the vessel then steamed down the Firth of Clyde, where its large cargo was instantly deposited through its bottom in 60 fathom water. This vessel dredges from 5 ft. to 35 ft. depth, has twin screws, and is propelled and worked by two independent sets of compound engines of 700-horse power, and besides loading its own cargo, it can fill if required a fleet of barges on the old system. It is the property of the Otago Harbour Board, and will steam to New Zealand. The trial of dredging, steaming, manœuvring, and depositing, was considered very satisfactory; this being the tenth and largest hopper dredger constructed by Messrs. Simons & Co., who are the inventors and originators of the system. It is also worthy of note, that owing to the enterprise of the above small colony, they will have a dredger the equal of which is neither in Europe nor America.

BOARD OF TRADE EXAMINATIONS.

Return of Engineers reported to have passed examination under the provisions of the Merchant Shipping Act, 1854, during the month.

LONDON, OCTOBER 1, 1881.

EDITORIAL NOTES.

The explosion of the *Doterel* has drawn the forcible attention of the authorities to the accumulation of gas in the coal bunkers of Her Majesty's Navy. We understand that the alterations in most of the Navy are to be very radical and thorough. Enquiry has elicited the information that there is scarcely any important vessel in the Navy that has not experienced such an explosion, but as they have generally been unaccompanied with serious results, not much attention has hitherto been paid to them. When the gas has had room to expand, and the adjacent parts have been iron, no great inconvenience has been experienced. It is now, however, determined to remove, as far as possible, all chance of the recurrence of such explosions, and extensive alterations are being made on board the *Inflexible*, now at Portsmouth. When the Channel squadron returns to England after the forthcoming cruise, the *Agincourt*, *Minotaur*, and *Northumberland* will be also overhauled. We understand that every ship in the Channel squadron has experienced at least one such explosion in the course of the last two years, and the *Minotaur* no less than three times. What is the experience of the mercantile engineers in this matter?

The Thames is shortly to see great modification and extension of its docking accommodation. It is absurd to see the present enormous, lengthy, and deep draught steamers creeping cautiously up the winding and narrow reaches of the Thames, obstructed as they are, in addition, by all sorts of crafts and barges. New docks are already proposed both at Gravesend and at Tilbury, nearly opposite the latter, by the East and West India Dock Company. This latter, if carried out, which we do not doubt will be the case, will be one of the greatest dock enterprises in the world, and have the greatest effect upon the encouragement of London mercantile commerce. It is proposed to purchase 480 acres of marsh land at Tilbury, which lies between the river and the London, Tilbury, and Southend Railway. The communication is thus very direct through the latter railway, with Fenchurch-street, with the Companies' warehouses, and with the great trunk lines of railway. It is intended to construct docks with a river entrance of 200 ft. wide, opening into a basin 16 acres in extent, with a lock 700 ft. long, and 41 ft. deep. The average depth of the main basin is to be 35 feet. The dock is calculated to give accommodation to 30 large steamers averaging 400 ft. in length. The estimated quay frontage is to be 15,000 feet, and graving docks, coaling, and fitting out berths, are also to be provided in the main dock. Large vessels need thus no longer anchor at Gravesend to wait for a flood tide up the river, but enter the docks at once, and thus save all river pilotage and towage. The estimated cost of all works, land, and expenses, is £1,000,000.

We are glad to see, or rather hear as yet, that the Engineers of the Royal Navy are at last to have some justice done them. We understand, on good authority, that the Board of Admiralty are at the present moment engaged in revising and amending the Code of Regulations defining the status of Engineers of the Royal Navy. It is understood that there will soon be many promotions from third to second class, and from second to first. Beyond this, the rates of payment, and the periods of active service necessary to qualify chief engineers for retirement, are to be materially improved. Greater inducement is also to be offered to young engineers of good education who may have passed a practical apprenticeship with private firms to enter the service. If these reforms are properly carried out, and the justice, so long delayed, at last rendered to the engineers of the service, so as to recognize them on equal terms, and as much gentlemen as their brother officers of the other branch of the service, there is no reason why the Royal Naval Engineering Service should not be as popular and well-filled as any other branches of the Military profession. There are many worthy Naval Engineers now afloat to whom the early pledges of promotion by the Admiralty, after certain years of service, have never been fulfilled. At last these crying evils seem likely to be remedied.

THE animated and continuous discussion on the tonnage measurement question in the daily papers, points out there is much room for improvement, and need for alteration in the present methods in use. It seems to us that there is a great deal of unnecessary personal bickering over terms and methods of measurement, whilst the grave question as to the advisability or otherwise of alteration from the present system is very much lost sight of. Who cares what particular rules are adopted for obtaining the different tonnage measurements, whilst no decision is arrived at as to the evils of the present system to ship-owners, or more especially to the ships themselves? There seems little doubt to our mind that in very many cases the seaworthiness of vessels is sacrificed to the object of making them carry the maximum cargo with the least tonnage measurement. And to an equal extent are the accommodations for captain and crew crippled and spoiled for the same reason. If these are accepted facts, and we see no reason to doubt them, they are crying evils infinitely worse than the question of any unequal incidence of rates in different styles of vessels. This latter point is only a market question which rights itself in the long run by the lowering of freights and passage fees where the tonnage dues were found to fall lightly or *vice versa*. The former is a question of life and death. We think certainly the great desideratum is a form of tonnage measurement which shall leave the greatest scope to builders to suit their vessels to their relative business with best attention to seaworthiness and comfort of passengers or crew. The rating by displacement tonnage only when light, leaves the whole conflicting question of maximum load-line on one side, and least affects the necessary covering of decks, the sheer of the vessel, and the construction of deck houses. This appears to us by far the simplest solution of the matter, and simplicity is always the greatest possible advantage in any system of measurement desired to become international. To spoil such an excellent solution by questions of equality of incidence is as bad as if each railway passenger's fare was assessed on the value of what he carried about him, or as if postage were charged according to the value of the contents of a letter. Tonnage dues are a charge for accommodation, which can best be assessed on external dimensions and draught, and ought not to be an income tax assessed on the value of the cargo carried.

THE principle of forced combustion to produce temporary acceleration of speed is now receiving more especial attention for general application to vessels of war. There can be little doubt that an increase of speed of two or three knots above average speed during an engagement, would almost certainly give the victory to any ironclad possessing that advantage over an otherwise equal antagonist. This additional access of speed it is easy to give, if the vessel is built on proper lines by a suitable arrangement of forced blast. The height of a steamer's funnel is always so comparatively low as not to afford any very considerable draught to the furnaces, and in tropical heat the draught is still further reduced. A steam jet in the funnel has already been used with some slight success in increasing the draught when desired, but a much more powerful and complete arrangement would be necessary to give the two or three additional knots which would be required to be of any service. It is still an open question whether this may be best obtained by more powerful induction steam jets, or by the closing of the ash-pit and fire-doors, and the injection of a forced blast by fans. We are inclined to think that the latter plan only will be likely to prove serviceable. A steam jet is a very wasteful way of attempting to produce a strong current of air, and if long continued and of great force will set up a tremor very destructive to the boiler. The volume of air injected by the fan may be increased or regulated at will, and the proportion of power required to drive the fan or fans is comparatively little. Besides, when not required for the furnaces, the blast of air may be made very serviceable for additional ventilation. Torpedo boats have already been fitted in this way by Mr. Thornycroft, and the *Polyphemus* is to be worked entirely on the system of a forced blast. No doubt this system will be soon largely extended throughout the fleet for use when in action.

NAVAL & SUBMARINE ENGINEERING EXHIBITION.

WE are glad to see that the Agricultural Hall is to be the scene next year of a novel and exceptionally useful exhibition. It is to be one representing the naval and submarine engineering manufactures, special attention being given to, and prizes offered for, the best inventions for saving life at sea.

The value of such exhibitions cannot be too highly estimated to the departments and trades represented therein. They most efficiently serve to bring suppliers and users into immediate contact in the simplest and most convenient manner. It is far too often the case that those who might benefit by the results of invention and progress remain in lamentable ignorance of what ingenuity may have effected for their benefit. Busy men have little time to pay attention to circulars or touters, and ideas presented in such a form take little hold upon the mind, even when heard, compared with the effect produced by the practical results of inventions experimentally shown.

There are few men, however busy they may be, but can find the time to make a visit to such a concentrated mass of information as is afforded by an exhibition. More particularly is this the case when the exhibition is limited to a definite class of exhibits. The international exhibits of general scope are far too vast, varied, and consequently incomplete in the different sections, to be of any very great business value to any manufacture or trade. The limited and distinctive class exhibitions held at the Agricultural Hall have hitherto proved most serviceable to the trades thus represented, and the Naval and Submarine Engineering Exhibition promises to be the most interesting and extensive of any yet held. Perhaps we are partial in this opinion, as feeling a special personal interest in the subjects of exhibition, but few have better opportunities than ourselves for knowing the immense variety, scope, and ingenuity now employed in the construction and equipment of our merchant fleet and navy.

Our merchant navy now musters nearly 40,000 vessels, of which one-fourth are steamers, and almost every day brings forth some improvement or novel apparatus for the better working of the powerful engines and numberless mechanisms with which modern steamers are now crowded.

Humanity also, in the form of safety from drowning, receives now-a-days a greatly increased amount of attention, and devices of great ingenuity and simplicity for that purpose require but to be seen to be appreciated. The opportunity and the prizes offered by the Naval and Submarine Exhibition will, no doubt, cause a most interesting number of these appliances to be practically exhibited in the large tank which is to be a great feature in the exhibition. This tank is specially devoted to submarine diving apparatus, and there is much that is new in this department that has only lately been introduced.

All manner of ship fittings, from boilers and pumps to distilling apparatus and tube expanders, are included in the special items of exhibits. Electricity in the form of lights, telegraphs, steering, and signalling apparatus will, no doubt, be conspicuously to the front amongst the more modern inventions, whilst ventilating apparatus will not be forgotten.

We look forward to this exhibition as promising a great treat in the mass of novel matter which we expect to be therein set forth, and we shall certainly do our best to make our readers *au fait* to all that there will be of interest therein.

HER MAJESTY'S SHIP "CONQUEROR."

THIS new steel armour-plated turret-ship and ram, which has been constructed at Chatham Dockyard, was successfully floated out of dock on September 8th, in the presence of a large concourse of spectators; but the attendance of the public was not so large as on the occasion of vessels being launched from slipways, the proceedings at a float-out being merely the hauling out of dock.

In some of its features the *Conqueror* is not uninteresting, and may with advantage be noticed. Perhaps the armoured ram *Rupert* will suggest the best idea of its character and capacity: It is like this vessel, but on an enlarged scale, and is, moreover, in many ways modified. Its length is 270 ft., and breadth 58 ft., the figures for the *Rupert* being 250 ft. and 53 ft.; but the mean draught is about the same—23 ft.—for both vessels. Whereas the displacement of the older vessels is 5,400 tons, that of the *Conqueror* is estimated at 6,200 tons; the indicated horse power of the two vessels being, respectively, 4,200 and 4,500; but the same speed of 13 knots is anticipated for both vessels. Generally speaking, therefore, in point of size, there is a fair resemblance between the vessels, but in a few striking points the difference is considerable. Notably is this the case with armour and armament. The introduction of steel and the invention of steel-faced armour have done a good deal to revolutionize construction, while the decision of the Government to introduce at once breech-loading ordnance into the British Navy has created a revolution in the armaments of men-of-war. Here it is, then, that the *Rupert* and her new-born sister part company. While the plating of the former vessel was limited to armour of from 10 to 14 inches thick of iron, the armour of the *Conqueror* will consist of steel-faced iron-plates of 12 inches thick at the water-line, 11 inches on the battery, and from 12 to 14 inches on the turrets. In point of thickness it will be observed that this plating is in no way thicker than that borne by the *Rupert;* but it may also be noted that this armour, with its face of steel, is calculated to be equivalent in point of resistance to four additional inches of iron armour as carried by the *Rupert.* In fact, this new device may be reckoned to be worth the addition of 25 per cent. of iron armour, and, for the purpose of comparison, the *Conqueror's* plating may be considered equivalent to from 14 to 18 inches of the iron with which the other vessel is protected. The deck armour which is now introduced generally into ironclad construction consists of steel plating of two and three inches thick.

The second important point of difference is in armament. While the *Rupert* carries two 25-ton guns of the old-fashioned muzzle-loading type, the *Conqueror* will be provided with four breech-loaders, two for the turrets, of 43 tons, and two six-inch guns outside the turrets, presumably for use as chase guns. It will be seen at once that there is no comparison between the vessels on this head. Both in character and calibre the new vessel has an overwhelming advantage over its rival. The decision to provide our men-of-war with this gun is so recent that an extract from Mr. Trevelyan's authoritative statement on the subject may be pardoned, and can hardly fail to be read with great interest. He states:—

"On the 24th of May last year the War Office wrote a letter to Sir William Armstrong, inviting him to send a breech-loading gun of 43 tons for an experiment. Sir William accepted the proposal, but asked for ten months to complete the task, so heavy and complicated were even the preliminaries of this great undertaking. There was some correspondence and a little difficulty before the specification of the gun could be arranged, but the Elswick gun was actually finished on the 11th of last month."

There it is at Woolwich, awaiting its trial; and this is the gun with which it is proposed to arm the *Conqueror*, care being taken to select, test, and complete the ordnance for this vessel and others now under construction in sufficient time to arm them when they are ready for sea. The other class of ordnance—namely, the four-ton or six-inch gun—has already been tried, and fourteen were ordered for the use of the fleet by Mr. W. H. Smith when he was at the Admiralty. In fact, so great is the progress with these powerful small guns that 103 are already ordered for the use of corvettes and unarmoured vessels, and a definite attempt has at length been made to remove the reproach to which the armaments of our large unarmoured vessels, such as the *Shah* and *Raleigh*, were justly open. It may be noticed that the *Conqueror's* turret guns fire over a clear upper deck, and command an uninterrupted training across the bow from about 50 feet abaft the beam on one side to an equal angle on the other. The value of machine guns, such as the Nordenfelt and Gatling, is now regarded as absolute in men-of-war, and provision has been made for a fair supply of these weapons; while in the matter of torpedoes provision is made for the use of the Whitehead under water, as in the *Inflexible*.

The vessel has been nearly three years in course of construction, but she is still in an incomplete state, and will not be ready to be commissioned for some time to come. When she left the dock her draught of water forward was only 10 ft., but then a large number of her armour-plates have yet to be placed in position.

The time fixed for the floating out of the vessel was twelve o'clock, and by that time numbers of persons had assembled. A small platform had been erected at the head of the dock for the accommodation of those taking part in the ceremony and for officers in uniform. Among those present were Vice-Admiral Sir J. Macdonald, K.C.S.I., Commander-in-Chief at the Nore; Rear-Admiral T. Brandreth, Admiral-Superintendent of Chatham Dockyard; Major-General the Hon. R. Monck, Commandant of the Chatham district; Colonel Sir A. Clarke, K.C.M.G., C.B., C.I.E., Commandant of the School of Engineering, Chatham; Colonel-Commandant Connolly, R.M.L.I.; Mr. R. P. Saunders, chief constructor; Mr. Stainer, Constructor; and the Rev. W. B. Smith, B.A., dockyard chaplain. The band of the Chatham division of Royal Marines was present, and played several pieces before the ceremony. Just before twelve o'clock the dockyard chaplain read the prayers appointed to be read at launches, the people uncovering. The "christening" was performed by Lady Clarke, wife of Sir A. Clarke. The apparatus used for christening the vessel was similar to that used at launches. After this ceremony the vessel slowly left the dock, being hauled out by means of ropes in the hands of a large number of dockyard men; and after getting into the river, the vessel was moored alongside the iron battery *Thunderbolt*. The whole of the workmen in the yard were granted a half day's holiday. The arrangements in connection with the floating-out were carried out most successfully under the direction of Mr. R. P. Saunders.

SILICATE COTTON OR SLAG WOOL.

A REALLY good non-conducting covering for boilers and steam pipes is a very great desideratum on board ship. The spaces reserved for stoke-holes are so confined and so badly provided with fresh air, that the heat is frequently unbearable, as many of our readers know.

When so good and simple a non-conducting covering as the new and improved form of silicate cotton or slag wool is to be had, it will be great remissness on the part of ship-owners if the stoke-holes are not for the future made comparatively cool and comfortable.

Slag wool is produced from iron slag by the passage through it of a blast of steam. This product has been known for some years, but hitherto it has been in a loose and friable condition, which has afforded many objections to its use. The only method of application formerly has been to pack the loose slag wool under a wood or iron casing, where it would gradually pulverize and settle to the bottom of the casing, losing at the same time its principal non-conducting properties, and besides be liable to get into parts of the machinery. The broken portions of the slag wool were also most irritating, and almost dangerous to the lungs of those who might inhale them.

Messrs. Daniel H. Dade & Co., of Bermondsey, however, have not been deterred by all these objections to the use of this novel and valuable material. They, who were, we believe, the first to introduce it, have, after many months' experiments, perfected processes by which silicate cotton is made into a composition, boards, cement, plaster or powder, as may be most convenient for a large variety of purposes.

In all of these forms the fibre is so held together that there is no longer any annoyance from floating particles. At the same time the porosity of the material, which is essential for its non-conducting properties, is fully maintained.

The Silicate Cotton Composition seems essentially suitable for boiler coverings for many reasons beyond its excellent non-conducting properties. When laid on it will not crack and peel off with the heat, as far too many do, nor will it char or burn like felt, but is practically indestructible. Though light, elastic, and porous within, it forms a hard, smooth external skin, which may be varnished or painted, and thus made to look beautifully neat and tidy. It can also be easily removed and re-applied when necessary, whilst its cost is cheaper than any other non-conducting material or lagging with which we are acquainted.

The directions for use are very simple, and may be carried out by any ordinary workman.

The necessary coating is now supplied by the latest improvements ready mixed to the consistency of thick cement. It is applied by being thrown somewhat forcibly on to a hot surface (that corresponding to about 5 lbs. of steam will suffice) in small patches—not too closely together—each successive coat filling up the open spaces left in the one underneath, until a thickness of two inches all over has been obtained. The smooth outer surface can be obtained when the material is half dry by smoothing over first with the hand, and then with the trowel or straight-edge.

When it is desired to remove and re-apply the covering, it can readily be taken off by a knife and by damping, and the composition can be reduced to its former condition of cement by admixture with a special silicate cotton fluid, when it can be applied as before.

The boards or sheets of silicate cotton are also a ready and simple means of covering surfaces when cold, securing by any adhesive material or light outside hooping. These boards have the additional advantage of being readily removed and re-applied.

For water, steam, or other hot pipes, an exceptionally handy means of covering is supplied in the form by long split rings or cylinders, from 1 to 3 feet in length, which are sufficiently elastic to admit of being opened and sprung over the pipe, overlapping each other at one end. We are inclined to think that this material will come into exclusive use as a boiler or other non-conducting covering

THE HYDROMOTOR.

THE above title has been given to a novel marine motor, the invention of Dr. E. Fleischer, and which promises to effect a startling innovation in the marine world. It is well known that in the ordinary marine engine there are immense margins of loss between the development of power in the boiler, and its visible representation in the speed of the vessel. To such an extent does this loss exist in the frictional resistance of the engines, and in the slip of the propeller, that not much more than 33 per cent. of the indicated horse power is absolutely obtained in the form of nett work. Any invention then which promises to dispose of a large proportion of both these losses is worthy of the closest attention from marine engineers and ship-owners.

It has already been proved by experiment, many years ago that the efficiency of a water jet for propulsion is greater for the exertion of a given power than that of the ordinary screw propeller. All vessels, however, to which hydraulic motive power has been fitted, have had the great disadvantage that the hydraulic jet was produced by engines and pumps which both experience a considerable margin of loss between their gross and nett effect.

Dr. Fleischer has successfully introduced the Hydromotor as an apparatus for producing a propelling jet of water by the direct action of the steam, and thus saving the loss by friction and leakage of the engines and pumps hitherto employed for such a purpose.

This apparatus has been fitted to a small vessel of 105 tons called the *Hydromotor*, which is 110 ft. long by 17 ft. beam, with a draught of 6 ft. to 6 ft. 6 in., and which has made a very successful voyage from Kiel to Copenhagen and back.

As fitted to the *Hydromotor*, the apparatus consists of two reservoir cylinders, *l l*, each furnished with a large pipe, *g*, leading from the bottom of the cylinder tothe nozzle, *n*, outside the vessel, as shown. Each cylinder also is provided with a float, *f*, of nearly the same diameter as the cylinder. At *d* and *k* are respectively the steam inlet and the exhaust valves, the latter opening to a pipe which conducts the exhaust steam to the surface condenser *m*. At *l* is a valve which during the exhaust stroke allows water to flow through the surface condenser into the working cylinder. The steam inlet and exhaust valves just mentioned are worked by means of a rod fixed to the float in the cylinder, there being provided at the top of this rod feathers which work in a grooved bonnet or guide fixed on the top of the cylinder. A second movable bonnet with a curved groove permitting a semi-rotary motion is fitted over the first, and to this upper bonnet are fitted discs or cams which operate the steam and exhaust valves, and effect the cut-off at any desired part of the stroke. The action of this apparatus is as follows :—

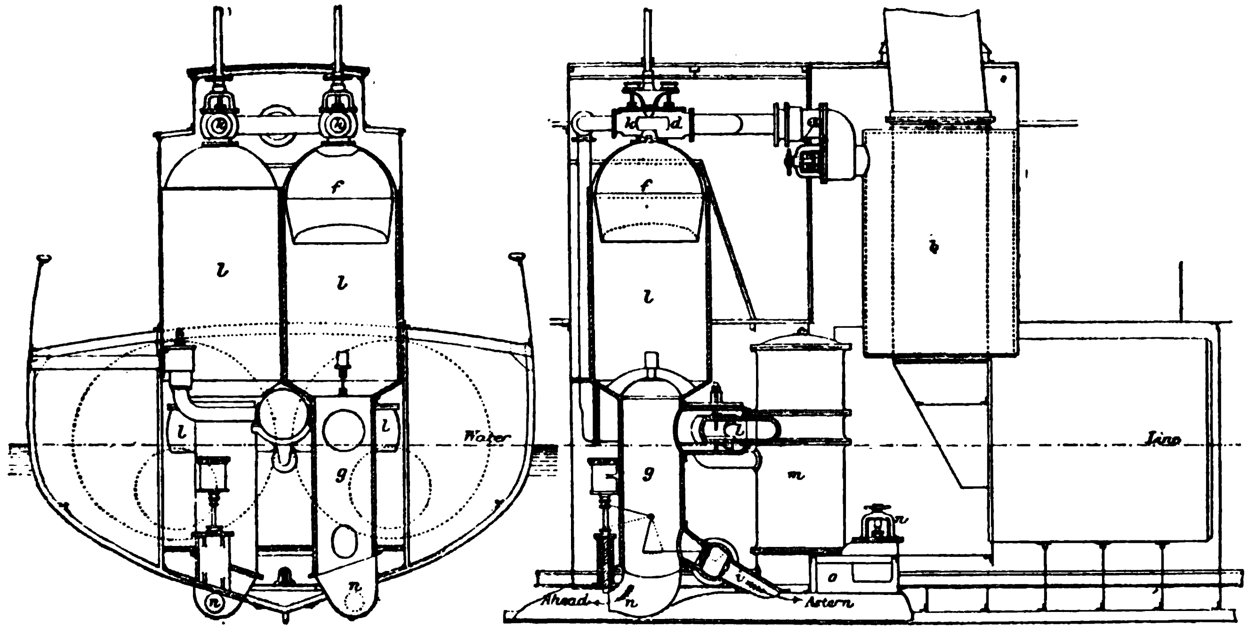
Confining our attention to one of the reservoir cylinders, let us suppose that it is full of water, and the float consequently at the top. In reaching this position the float will have opened the steam valve, and the steam entering the cylinder will press down the float and eject the water beneath it at a great velocity through the nozzle, *n*. The float will thus descend until at a certain portion of its stroke the rod above mentioned will close the steam valve, the expansion of the enclosed steam being then utilized in completing the down stroke and ejecting the rest of the water. Just as it reaches the bottom of its travel the float opens the exhaust valve, when the steam rushes into the condenser, and a partial vacuum being formed in the reservoir cylinder the water rushes in partly through the nozzle, *n*, but principally through the suction valve, *l*, thus raising the float and bringing it again to the top of the cylinder ready for the same cycle of operations to be performed. In the Hydromoter there are, as shown in our engravings, two reservoir cylinders which perform alternate strokes. In larger vessels the number of reservoir cylinders may be multiplied to any desired extent.

If it should be desired to drive the vessel astern, all that is necessary is to admit steam to the top of a small vertical cylinder shown fixed by the side of the pipe, *g*. The steam thus admitted will cause the piston of the small cylinder to descend, thus sliding down a sluice door in front of the nozzle, *n*, and at the same time through the arrangement of levers and links, shown by dotted lines, opening a valve which allows the water in the reservoir cylinder to be ejected through the passage, *i*.

The loss of steam by internal condensation in the cylinders is as the indicator diagram shows, very small, because a heated surface of water leads heat downwards but very slowly. Besides the cylinders are lined with lignum vitæ, which has a low specific heat, and is a bad heat conductor.

It is evident that nearly the whole steam power may be utilized most directly in the working stroke, and the full value of the vacuum may be realized by placing as high a working chamber as possible; the velocity of the jet will be thus increased by the column of water drawn in by the vacuum. The diagram we publish shows very satisfactorily what takes place in the working stroke, and looks like a very fair engine diagram.

The following tabular comparison of the results obtained from the *Hydromotor*, compared with the *Waterwitch* and *Rival* [turbine ships] at once gives the leading place to the *Hydromotor* :



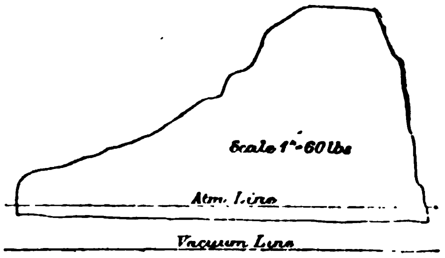
THE HYDROMOTOR.

Name of vessel	Waterwitch.	Rival.	Hydro-motor.
Displacement in tons ...	1279	about 170	105
Area of midship section ...	...	91 sq. ft.	61 sq. ft.
Speed attained	9 3 knots	7 knots	9 knots
Description of machinery..	Engine driving centrifugal pump	Engine driving centrifugal pump	Fleischer's Patent Hydromotor
Indicated horse power ...	760	292	100
Coal consumpt'n. per hour	...	832 lb.	255 lb.
Area of discharge opening	5.33 sq. ft.	3.63 sq. ft.	0.29 sq. ft.
Velocity of discharge of water in feet per second..	30 ft.	23 ft.	66 ft.
Water discharged per minute	9000 cub. ft.	5000 cub. ft.	700 cub. ft.
Horse power accounted for in the water discharged..	267 H.P.	77 H.P.	89 H.P.
Loss	64.9 per ct.	73.7 per ct.	11 per ct.

The great point of value to be noticed from these results is that the loss by transferring the steam power to the water jet is only 11 per cent. in the case of the *Hydromotor;* whilst in the only other test cases of hydraulic propulsion the margin of loss has been 64·9 per cent. and 73·7 per cent.

Hydraulic propulsion has thus, by Fleischer's invention, been placed at least on a par as regards economy with the best results of screw propulsion. The benefits resulting from jet propulsion also increase with the speed, so that for the high speeds the advantages of economy of jet propulsion will be still greater than can be at present anticipated.

A further great advantage of the Hydromotor is, quite apart from its wonderful simplicity, that all its power can be utilized to keep the vessel clear of water in the case of a leak. The dangers of breaking shafts or fouling propellers are all obviated, and a general break-down might be considered impossible.



The vessel fitted with a hydromotor is particularly well under control, as the driving power can be reversed from the captain's bridge without stopping the apparatus.

We read that the celebrated German Admiral Werner was present at the voyage of the *Hydromotor* to Copenhagen, and is of opinion that the invention is a fact which signifies a new phase in the development of navigation. Dr. Fleischer is now in London for the purpose of transferring all his patents to an international Society which shall exploit the invention in all countries.

EXHIBITION OF MACHINERY AT BIRKENHEAD.

IT is worthy of mention, as having a special interest for shipping, that at the recent Exhibition of Machinery at Birkenhead, a Silver Medal was awarded for a direct steam windlass, manufactured by Messrs. Emerson, Walker & Co., London, and exhibited by Messrs. Cochrane & Co., Duke Street, Birkenhead. The opinion of gentlemen who inspected the invention was that it is admirably adapted for its purpose, and that the manufacturers were thoroughly deserving of the distinction conferred upon them.

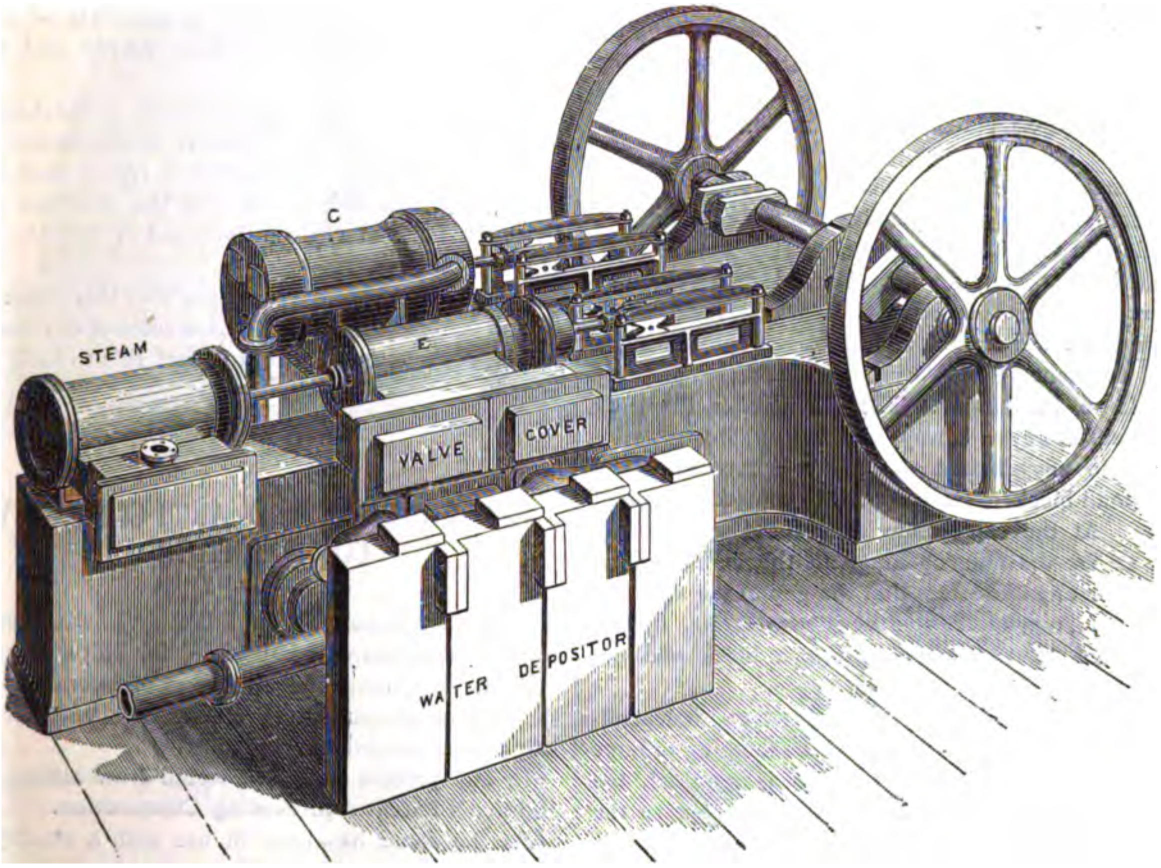
LIGHTFOOT'S PATENT SELF-CONTAINED DRY AIR REFRIGERATOR.

MR. T. B. LIGHTFOOT, Consulting Engineer, of 116, Fenchurch Street, E.C., has, as is well known, for a long time paid great attention to the subject of the mechanical refrigeration of air, both in regard to its production and application, a most interesting Paper on Cold Air Machines having been read by him before the Institution of Mechanical Engineers at their meeting held in London last January.

A number of refrigerators on one or other of Mr. Lightfoot's patents have, from time to time, been constructed and put to work, some for the freezing and preservation of meat in Australia, and others for use in manufactures where some means of producing rapid cooling was required, and we now illustrate by the perspective view above, a type of machine which though at first specially intended for use on shipboard, has now superseded previous arrangements for all purposes.

The particular machine we illustrate is in use at the Royal Victoria Docks for cooling a series of chambers for the storage and preservation of meat, fish, butter, or any perishable food, and is capable of delivering about 10,000 cubic ft. of air per hour at a temperature of about 50 deg. below zero Fahr.; which is roughly equivalent to the cooling of a chamber space of from 9,000 to 10,000 cubic ft., provided ot course the walls of the chamber are suitably constructed of a heat proof material.

The air after being compressed to a pressure of from 45 to 65 pounds per square inch, (according to the temperature of the cooling water) is passed through a series of coolers, so that it may be deprived of the heat imparted to it during compression. During this process the temperature is brought down to within 5 deg. or 6 deg. of that of the entering cooling water, and a considerable portion of the moisture passing in with the air is condensed and deposited. After being cooled the compressed air is admitted to the expansion cylinder; but as it still contains a large quantity of water in solution, which if expansion be carried immediately to atmospheric pressure, would from the extreme cold, be converted into ice, with a positive certainty of causing great trouble in the valves and passages, it is got rid of by a process invented by Mr. Lightfoot, which is not only most efficient in its result, but at the same time very simple in action. Instead of reducing the compressed air at once to atmospheric pressure, it is at first only partially expanded to such an extent as will give a terminal temperature of about 35 deg. Fahr., with the result that almost the whole of the contained aqueous vapour is condensed into water. The partially expanded air which now contains the water as a thick mist, is then admitted into a vessel called the "separator," containing a number of inclined surfaces, through which it passes, parting all the while with its moisture, which gradually collects at the bottom and is blown off.



LIGHTFOOT'S PATENT SELF-CONTAINED DRY AIR REFRIGERATOR.

The area of the surfaces is so proportioned that by the time the air has passed through them, it is quite free from moisture, with the exception of the very trifling amount it can hold in solution at about 35 deg. Fahr. and 30 pounds pressure. The expansion is then continued to atmospheric pressure and the cooled air, containing only a trace of snow is then discharged ready for use in a meat preserving chamber or elsewhere.

The double expansion is carried out in one cylinder, containing a piston and trunk, the primary expansion taking place in the annulus and the final expansion against the whole piston area. To compensate for the varying temperature of the cooling water the cut off valve to the first expansion is made adjustable, and this can either be regulated by hand or it can be made to alter automatically. The temperature in the separator being kept constant under all variations in cooling water, there is an abstraction of moisture to the same degree of dryness whether the machine is at work in temperate climates or in the tropics, and the cold air finally discharged is also kept at a uniform temperature.

The air in expanding, gives back about 50 per cent of the power used in compression, and the difference, plus the friction, must be applied to the machine, either by a steam cylinder acting as that shown in the engraving, or else through gearing or belting. Mr. Lightfoot hopes by some improvements recently made, to reduce the driving power to a considerable exten below what has hitherto been required.

HYDRAULIC MACHINE TOOLS. TWEDDELL'S SYSTEM.

TO compete successfully as a manufacturer, labour-saving tools of the most improved construction are a prime necessity. Those marine engineering firms who are of this opinion will readily recognize the value of the improved flanging machine we herewith illustrate. Flanging by hydraulic power is, we know, not new, but this improved machine on Tweddell's system, as constructed by Messrs. Fielding & Platt, has special and novel features of value.

The usual construction of a hydraulic flanging machine, as hitherto employed, has necessitated the use of expensive dies and blocks, in order to flange the largest plates or boiler fronts at one operation.

The machine we illustrate is modified into the form of a comparatively inexpensive shop tool, which is capable of a very large variety of work.

The largest flanging may be undertaken by successive operations somewhat resembling hand work, and with the use of a block or matrix, representing a small segment of the circle to which the plate or front is to be flanged. The character of the work need not, however, always be circular, but may be oval or to any desired sweep. It is necessary only for a small block to be prepared to suit the required curve. At the same time small circular flanging, such as for the flue openings in the boiler fronts, domes, or any diameters that the gap of the machine will take in, may be effected at one operation by the conversion of the machine into a block and die flanger, as shown in the second figure.

The machine consists essentially of two independent hydraulic rams, C and D. When flanging of large diameter or of an irregular curve is required, the suitable curved block or segment F is bolted to the lower bed-plate, and the plate is clamped in position by the hydraulic head, C. The other hydraulic head D, carrying a special tool, travels downwards in a guide temporarily bolted to the bed-plate, and bends over the edge of the plate as required. If the flanging is to be a circle of large diameter, the plate is carried on a temporarily fixed revolving centre, G, so that the plate can be rotated and all parts of the plate brought in succession under the flanging head.

To perfect the squareness of the flanging, a horizontal ram, E, and head, K, may be fitted in the main standard, which may press home the lower edge of the flange squarely up against the block.

The edge of the plate to be flanged is of course heated in convenient lengths, at present about 4 ft. in extent; but if the furnaces were increased, there seems to be no difficulty in flanging from 5 ft. to 6 ft. in one heat.

When flanging in small diameters is desired, both hydraulic rams are placed in communication with each other, and are united by the circular flanging die, M, as with a cross-head.

A suitable block or matrix, N, is bolted upon the bed-plate, from which the former guide and block has been removed. The circular flanging can thus be effected at one operation.

It is evident that straight flanging can be equally well carried out in this machine, and its capabilities are thus immense and suitable to any class of work, whilst the machine itself is very simple and inexpensive.

The ultimate advantage of such a machine to manufacturers would lie, however, in the economy of work, so we are glad to be able to report that up to now the results have been that the machine does twice the work in a given time, and at half the cost of hand flanging.

It is thought, however, certain that this result will be still further improved. Perhaps some of our readers would wish to be the first to effect this to their own benefit.

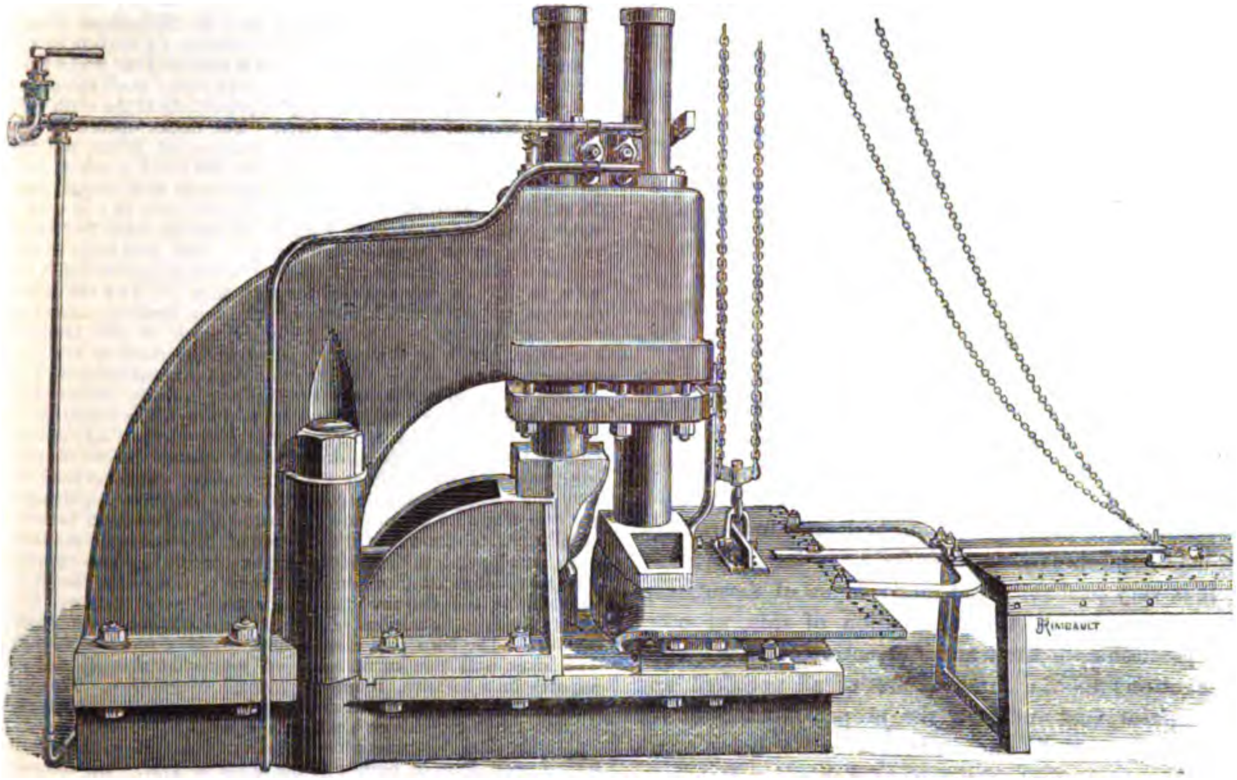
ANTI-FOULING AND ANTI-CORROSIVE COMPOSITIONS.

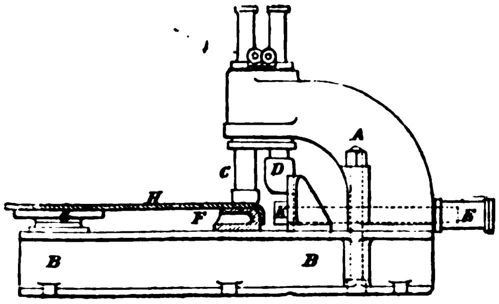
IN our last issue we drew attention to the question of anti-corrosive composition for ships' bottoms, and are in consequence in receipt of information on the subject which will prove, doubtless, of interest to shipowners and others.

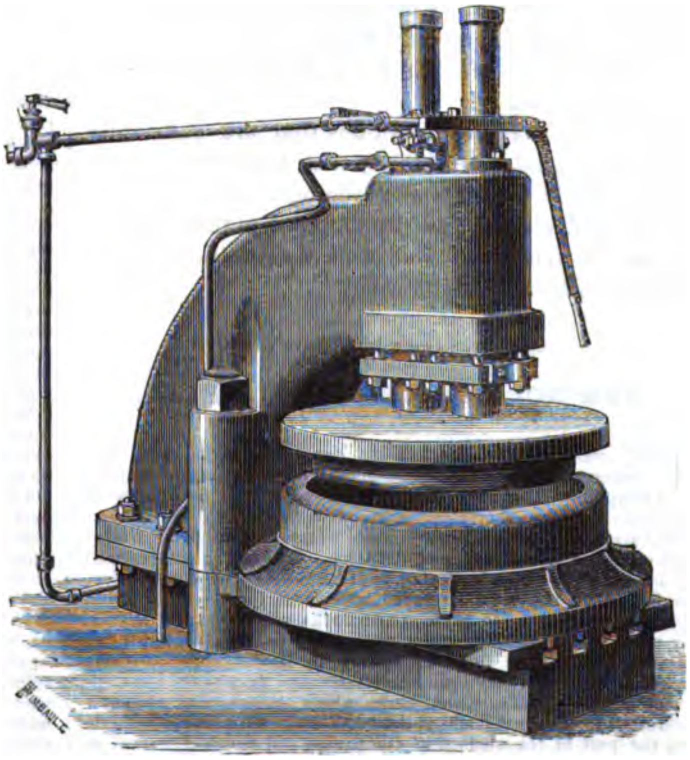
In our present notice we would draw attention to Rahtjen's Patent Anti-Fouling Composition.

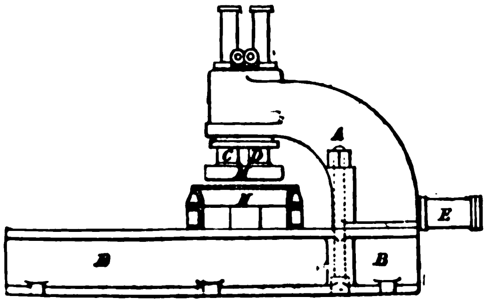
As the same has been in use with a steadily increasing business, since 1865, there must be much to practically recommend it. We find that the great majority of iron steamers have been coated with this composition since its introduction up to the 30th of June, 1880, including the entire fleet of the Peninsular and Oriental Steam Navigation Co., and many other well-known and prominent lines of steamers, both English and foreign.

The advantage arising from any means that will prevent the accumulation of barnacles and grass on the hulls of vessels, is generally well known, with regard to the increased speed thereby obtained, and the economy of coal effected in the case of steamers. It has often been shown that steamers coated with the composition have mostly made much faster pas-









HYDRAULIC FLANGING MACHINE.

sages than before, owing to the smooth slippery surface it has. It is a known fact that on tallow or other greasy surfaces the water clogs and does not run off so quickly as on a smooth, hard surface. Especially on steamers, where the friction is much greater than on sailing ships, it is necessary to have a paint that does not wear away too soon.

We find that Rahtjen's composition will mostly prevent all fouling, except a thin coat of slime, easily removed by washing, for a period of twelve to fifteen months. And even when so long a period as two years has been allowed to elapse before dry docking, as it was the case with the ss. *Faraday*, there is good evidence to prove that very little fouling has occurred that could not be easily removed by scrubbing down, and the body of the paint seems to have stood so well, that the iron was found to be in first-rate preservation. We see that in the case of this composition, as in others, some slight discrimination must be used, and directions attended to in its application.

It is very probable that many cases of dissatisfaction may arise in the application of this, or other compositions, for the want of attention to such simple precautions as the removal first of all perished and loose paint, rust and dirt, the proper stirring of the paint both in cask and in kettles, when being used, and the addition, when required for thinning Rahtjen's composition, of methylated spirit only, and no other substance whatever. Evaporation, also, from a package once opened, and only partly used, will go far to spoil the nature of such a composition when next required for use.

Out of the many compositions that are constantly brought forward, we must say that, from personal enquiries made amongst the leading steamship companies and owners, we have found nothing but a favourable opinion of Rahtjen's composition, which we have selected for attention.

NEW NORTH DOCKS AT LIVERPOOL.

THE commerce of the Mersey develops rapidly, and this necessitates constant additions to the dock accommodation of Liverpool. This necessity is increased by the peculiarity of modern commerce, the vessels engaged in which are to a considerable extent steamers of great length, which require to be loaded and unloaded with the utmost despatch. Hence the construction of long narrow branch docks, with abundance of quay space, supplied with the most approved appliances for the loading and discharge of cargo. In these steam docks vessels do not lie side by side, but in berths by the quay; and as each company has allotted berth space they can collect on their respective quays goods for shipment by their next steamers. It was the development of Liverpool's steam trade which necessitated the new additions to the great docks at the north end. Frequent complaints on the part of the steamship companies, and much agitation in commercial circles, caused the Mersey Docks and Harbour Board, in 1873, to instruct their engineer (Mr. G. F. Lyster) to prepare plans for an extension of the dock system. The plans were prepared, and, after some opposition in the interests of Birkenhead (where the Board also possesses docks), were approved, the shipping and trading community in general objecting to any attempt to compel owners to send their vessels into the Birkenhead Docks. Parliamentary powers were obtained to borrow £4,100,000 on the security of the dock rates, and with this authority the works have since proceeded. These new works comprised dock extensions both north and south of the dock (but principally at the north end) on the Liverpool side of the river. The docks opened by the Prince of Wales, and named by the Princess of Wales, add 110 acres of water space and more than six miles and a half of quay berthing to the accommodation for the trade of Liverpool; and the entrances of these new docks have their sills laid at a level which gives a depth of 23 ft. 7 in. on an average neap tide and of 30 ft. 10 in. on an average spring tide. The advantage of this will be obvious. The general class of vessel using the docks can enter or leave at any state of the tide, thus avoiding the delays, expenses, and risks which have hitherto been incurred. The new docks are situate in Bootle, 3½ miles north of the Liverpool Exchange. It is at the north end where the trade of the great steamship companies is for the most part concentrated, the most modern docks of the Board's estate being already situate there. The entrance to the new dock system is through the Canada Basin in which the tide ebbs and flows, and which forms a sort of vestibule to the most northern docks which existed before the latest additions. But this basin at the mouth of the river has been considerably enlarged and deepened to meet the new requirements, and the width of its entrance from the river has been increased from 250 ft. to 400 ft. On each side of this entrance are being constructed piled timber jetties or piers projecting into the river. These are intended (one on the north side is already completed) to facilitate the entrance and departure of vessels, as well as to assist sluicing operations to keep the entrance clear of silty deposits. The horn pier, already finished, is a remarkable work. The river wall here curves outward somewhat sharply, and terminates in a massive, rounded pierhead of granite. The jetty projects backward from this about 40 ft., and ends in another pierhead of concrete, whence another arm extends to the river wall. The main jetty is supported by enormous posts of greenheart let into a solid base of granite to the depth of 17 ft. On the north end of the horn pier is a small look-out tower, and beside it is an ironwork standard 80 ft. high for the electric light. The entrance to the Canada Basin is in an exposed position, and the peculiar form of the river wall serves to break the force of the waves which dash up against it in stormy weather. On the north side of the Canada Basin are two passages by which the newly-constructed docks are reached. The first is the Langton Dock, with a water area of 18 acres and a quay or berthing space of 4,000 ft. in length. Opening from the eastern side of this dock are two graving docks (each 951 ft. long), which may be subdivided into four docks, each of sufficient extent to accommodate a vessel of the largest class while being repaired or overhauled. On the quay between these graving docks buildings are erected, which contain powerful engines and machinery for pumping the graving docks. Here, also, are powerful engines which supply the motive power that actuates the hydraulic machinery for opening and closing the dock gates, bridges, sluices, working cranes, and other mechanism throughout the new system. Over this great engine-house are a number of dwellings built on the "flat" system for the foreman and engine men. On the quay is also constructed a clock tower 120 ft. high to enclose the accumulator. The group of buildings is in a free Gothic sort of architecture. On the east side of the Langton Dock (and north of the graving docks) is also a branch dock, with three acres of water area and 2,013 lineal feet of berthing space. A hydraulic crane to lift 100 tons is being constructed on the south quay of this branch dock for moving heavy boilers and machinery. On the north side of the Langton Dock are two passages which lead to the Alexandra Dock specially constructed for steamers of vast size, and named after herself by the Princess of Wales. The Alexandra Dock is 1,600 ft. long from north to south, and opening on its eastern side are three branch docks which extend inshore almost to Regent-road, a main thoroughfare which flanks the north docks. These branch docks vary in length from 1,100 ft. to 1,338 ft., and with the Alexandra Dock itself have a water area of 44½ acres, and provide 11,814 lineal feet of quay berthing space for ships. The dock walls are mostly built of cement concrete faced with red sandstone of the district, and with a coping of granite, while the entrance walls are faced with granite. The steps and slips of the graving docks are constructed of granite, but in other respects these docks are built of concrete. All the dock gates are made of greenheart timber, which Mr. Lyster considers the most durable wood for this sort of work. The berthing quays of the new docks are provided with lock-up sheds, 80 ft. to 95 ft. wide, for the protection of cargo in transit, and these sheds directly communicate by road with the city, and by rail with the stations of the several great railway companies who have termini in Liverpool. In the west gable of No. 1 Branch of the Alexandra Dock has been inserted a fine piece of stone carving lately discovered in the interior of the King's tobacco warehouses, at the south end of the docks. It represents the arms of Great Britain before they included the shamrock, and is supposed to have been in the old tobacco warehouses erected in the reign of George III. The arms have been recut, and surrounded with an ornamental border with the Prince of Wales's plumes on each side, and "Alexandra Dock" inscribed on granite below. There is also another granite slab inscribed "These arms of Great Britain in the reign of George III. were removed from an old building on the dock estate, and are re-erected here as a memorial of the auspicious visit of their Royal Highnesses the Prince and Princess of Wales on the occasion of the opening of these docks, September 8, 1881." A floral border round this includes the shamrock absent from the old arms. On the east side of the main entrances by which vessels enter this new group of docks a solid block of buildings—a free adaptation of the domestic Gothic in style—is being erected to provide residences for the dock master, pier masters, gatemen, and other officers. North of the Alexandra Dock is being constructed another new dock with 16 acres of water area and 4,000 ft. of quay berths, but this is incomplete, and needs no further notice at present. The land where the docks have been constructed was purchased many years ago, and, after the completion of the dock mentioned as in progress of construction, 80 acres of the old purchase will yet remain for utilization. The river wall extends to the southern limit of the estate, and in time the promenade, 21 ft. wide, already open for a considerable distance, will extend across Bootle to Seaforth. The whole of the docks northward from the Prince's Dock are completely enclosed either with a wall 14 ft. high or with loftier buildings, thus protecting the ships and quays from depredations.

ON THE PROGRESS AND DEVELOPMENT OF THE MARINE ENGINE.*

By Mr. F. C. Marshall, of Newcastle-on-Tyne.

(*Continued from page* 132.)

THE marine boiler of to-day is in all its main features the same as it was ten years ago.

The single-ended boiler, made with two, three, and sometimes four furnaces, is the simplest form, and for all powers under and including 500 indicated horse power is the most generally adopted.

The double-ended form is largely used. It has been found more economically efficient than the single ended form, by as much as 10 per cent. in the writer's own experience. It is generally adopted for engines of large power, but for small powers is inconvenient, owing to its occupying more room lengthwise in the vessel, and also involving two stokeholds, and therefore more supervision. At one time great difficulty was found in keeping the bottoms of boilers of this kind tight. Owing to their length, the unequal expansion due to different temperatures at the top and bottom caused severe racking strains on the bottom seams and rivetting, so severe in some cases as to rend the plating for a large part of the bottom circumference of the shell. This difficulty has now been to a large extent got over, in consequence of the greater attention given to the form and direction of the water spaces in the boiler itself, so as to induce circulation of water; the introduction of the feed water at the top instead of near the bottom; the more careful management now usual on the part of engineers; and lastly, the use of larger plates, welded horizontal seams, drilled rivet holes, and more perfect workmanship throughout.

In boilers having a single flame-box to two furnaces opposite each other, Fig. 7, difficulty has been experienced in keeping the ends of the tubes tight, owing to the action of the one furnace upon the other, and the inequalities of temperature induced thereby. This is now obviated by the introduction of a fire-brick division extending just so high as to prevent the current of air, when the door is opened from striking directly upon the opposite tube-plate.

The modification of double-ended boiler, shown in Figs. 8 and 9, is that introduced by Mr. Alfred Holt. It has many decided advantages, but is costly to make. The formation of the two ends into separate fire-boxes leaves the bottom of the boiler free to adapt itself to the variations of temperature to which it is exposed. The separation of the furnaces from the combustion chamber, excepting through the opening afforded by the connecting tube shown at A, is an advantage in the same direction, and avoids almost entirely the racking strains due to irregular furnace action. The weight of water carried is less, and that of the boiler may also be made less; while the elliptical form of the two ends gives greater steam space.

Figs. 10 and 11 represent a type of boiler largely used in Her Majesty's Navy, and very suitable for all classes of vessels where length is available. It is introduced here as a specimen of a highly efficient boiler in regard to weight and power developed. Many examples have yielded one indicated horse power in the cylinders for every 3 square feet of heating surface, under natural draught and with a very moderate height of funnel; and this with a consumption of fuel not exceeding 2¼ lb. per indicated horse-power per hour under a working pressure of 60 lb. With the aid of a steam jet in the funnel, the heating surface per indicated horse-power has fallen below 2½ square feet. The large water surface afforded for escape of steam secures almost entire freedom from priming, without the incumbrance of steam domes; and the large combustion chamber allows of the thorough combustion of the gases before their passage through the tubes.

The locomotive type of boiler has lately occupied the writer's attention, with a view to its more definite introduction into marine work. In his recent paper before the Institution of Civil Engineers Mr. Thornycroft has shown what can be done with it under a forced draught; and how to reduce the weight of boilers and the water in them, as well as how to get a large power out of a small boiler. This form of boiler (see illustration next No.) affords the opportunity of introducing an almost unlimited amount of absorbing surface in the shape of tubes, while the fire-box is in the best form possible for efficiency. The difficulties, however, which lie in the way of applying the same principles to steamers going long voyages, are very great. The principal difficulty lies in the necessity of burning a large quantity of fuel in a very limited space and time. This can only be done either by direct pressure or exhaust action applied to the furnace. In other words, we must either exhaust the funnel, which will absorb a large amount of power, but would be comparatively easy of application; or our stokers, as is the case with our miners, must work under a pressure of air. The writer would submit for the consideration of the meeting whether this latter is an unreasonable condition of things to contemplate, considering that by so doing we should enormously reduce the dead-weight of our boilers and water, and thereby leave room for a corresponding weight of cargo.

The boiler shown is that known as the Perkins boiler (see illustration next No.) and is introduced here as a specimen of the tubulous system applied to marine purposes. It must be admitted that the tubulous system has not been a success, as actually worked on board ship; the writer, nevertheless, submits that this system affords a means of reducing the enormous weight of boilers and water at present deemed necessary, which is well worthy our consideration; more especially as, with increasing steam pressures, this weight must still further be increased to the serious hindrance of progress, and loss to the shipowner by the displacement of freight-paying cargo.

With regard to the use of steel in marine boilers, the valuable Paper read by Mr. Boyd in 1878, and that read by Professor Kennedy at the last meeting, have left very little to be said as to the character and use of the material, and the mode of treating it. The writer wishes only to state the result of his experience in the manufacture and working of such boilers, with the view principally of removing the doubt and uncertainty, so freely expressed in the discussion on those Papers, and to some extent justified by the failure of the boilers of the *Livadia*. Many steel boilers of sizes varying from 6 ft. in diameter to 14 ft. 6in. in diameter have left the works at St. Peter's since 1877, when the first was made; and in no case has there been a failure of a plate after being put into a boiler, either in the process of manufacture or in working at sea. The mode of working is as follows: For shell plates, from ⅝ in. to ⅞ in. thick, to warm each to a dark red heat before rolling, having previously drilled a few holes to template for bolting the strakes together; the longitudinal seams are usually lap joints treble-rivetted, requiring the corners to be thinned, which is done after rolling. The furnace plates are generally welded two plates in length, and flanged to form Adamson rings, and at tin back end to meet the tube plate; the back flame-box plates are flanged, also the tube plates and front and back plates, and whenever work is put on to the plate it is annealed before going into place. The rivet holes

are drilled throughout. In the putting together the longitudinal seams of the thicker plates of the shells, great care is always taken to set the upper and under plates for the lap to their proper angle before they are bolted together, a point generally overlooked by the practical boilersmith. It will be observed that if this is not done, great strain is thrown on the material, sometimes resulting in fracture. In two boilers, made in another department of the works, fracture actually did take place while closing up the rivetting in four plates ⅝ in. thick; the rivetters having followed the old bad custom, so common in iron boilers, of drawing plates together when in place, in order to close the work the platers should have closed. The writer suggests that this may have been done in other boilers besides those mentioned. The use of steel for boilers is always recommended by the writer, and in no case has he had cause to regret it.

The question of corrosion is one which is gradually being answered as time goes on; and so far very satisfactorily for steel. Some steel boilers were examined a few weeks ago which were amongst the first made; and the superintending engineer reports, "There is no sign of pittting or corrosion in any part of the boiler; the boilers are washed out very carefully every voyage, and very carefully examined, and I cannot trace anything either leaking or eating away. No zinc is used, only care in washing out, drying out, and managing the water."

This is the evidence of an engineer with a large number of vessels in his charge. His statements could be corroborated by many other engineers in similar positions. On the other hand some of our most prominent Liverpool engineers always use zinc, and take care to apply it most strictly. The evidence of one of them is as follows: "We always fix slabs of zinc to most boilers, exposing not less than a surface of 1 square foot for every 20 indicated horse-power, and distributed throughout the boiler. This zinc we find to be in a state of oxide and crumbling away in about three months. We then renew the whole, and find this will last twelve months or more, when it is renewed again. Meantime, we have no pitting and no corrosion, but on the contrary the interior surfaces appear to have taken a coating of oxide of zinc all over, and we have no trouble with them." Again, many engineers have trouble with their boilers under both systems; this is due no doubt to some mismanagement, probably the admission of too much air with the feed water. Frequently, too, the tubes and interior surfaces are destroyed by drops of moisture being allowed to form and dry upon them after blowing out.

The superheating of steam, notwithstanding its undoubted value in all expansion engines, has practically died out. To some extent the use of much higher pressures has rendered it less necessary; but the practical difficulty of the rapid corrosion of the material of which the superheaters were made, and the restrictions imposed by Lloyd's and the Board of Trade on that account, have mainly led to their abandonment.

The most noteworthy feature of to-day in connexion with the marine engine is the demand for largely increased power, to meet the requirements of shipowners for larger vessels and higher speeds. There is a growing feeling amongst them that "speed pays;" and that it is better to insure certainty of arrival at the port of destination than to save a few tons of coal on the voyage. At the same time it is of the first importance that the required increase of speed and power should be achieved, first, with the least possible weight of machinery, water, and fuel to be carried; secondly, with the least possible expenditure of fuel; and thirdly, with safety and efficiency in working, low wear and tear, and cheapness of maintenance.

These points being kept in view, the writer proposes to consider our present marine engine as to its efficiency and capability of further improvement, and then to consider generally in what direction we may look for further developement; carefully separating throughout the boiler, or steam generator, from the engine, or steam user.

(*To be continued.*)

THE Peninsular and Oriental Steam Navigation Company's new steamer *Thames*, which has been built by Messrs. J. & G. Thomson, of Glasgow, was launched from their yard on September 26th. She is 390 ft. long, 42 ft. broad, and 35 ft. deep, with engines of 750 horse power nominal. The vessel will accommodate 120 first and 48 second class passengers, and will carry over 3000 tons of cargo. The first voyage of the *Thames* will be on the Company's Australian line.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of the* MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Princess.—On August 23rd Messrs. Day, Summers & Co. launched from their building-yard at Northam Iron Works, Southampton, a powerful tugboat for the Bombay Harbour Trust, which was named the *Princess.* This vessel is built of iron, and has the following dimensions:—Length between perpendiculars, 100 ft.; length over all, 104 ft.; beam, 23 ft.; depth from top keel to underside deck, 14 ft. 4 in.; tonnage, B.M., 242 tons. The *Princess* has a straight stem and semi-elliptic stern; she will carry 40 tons of coal in her bunkers, and 60 tons of cargo in her hold. She has a large forecastle forward and cabin accommodation for the captain and engineer aft, also a steam windlass. In order to give the greatest facility for handling this vessel, it was decided by her owners to adopt the twin-screw principle of propulsion, and she will therefore be fitted with two distinct and separate pairs of engines, each of 60-horse power nominal. These engines are compound, with cylinders of 20 and 40 in. diameter, with 24-in. stroke, and fitted with steam starting gear. The propellers have each four blades, and are 8 feet diameter, with a pitch of 14 feet.

Lismore.—On August 25th Messrs. W. Johnstone & Co., of Liverpool, launched at the yard of the Barrow Shipbuilding Company, a steamer of 4040 tons. She is registered of Barrow, and is intended for the cattle trade. Her length between perpendiculars is 376 ft.; extreme breadth, 42 ft.; depth of hold, 26 ft. with engines, indicating 2550 horse-power. She is fitted with a direct steam windlass by Messrs. Emerson, Walker & Co., London.

Hasland.—On August 27th Messrs. W. Gray & Co. launched from their yard at West Hartlepool an iron screw steamer of the following dimensions:—Length, 256 ft. 6 in.; breadth, 34 ft. 6 in; depth in hold, 19 ft. 8 in. She has been built to the order of Messrs. Groves & M'Lean, of West Hartlepool, and is intended for the American, Mediterranean, or Indian trade, and is 1,750 tons register. She is fitted with engines of 150 horse-power by Messrs. T. Richardson & Son, of Hartlepool, and has all the latest improvements, including four steam winches by Clark, Chapman, & Gurney, and patent windlass by Emerson & Walker. On leaving the ways the vessel was named the *Hasland*, the christening ceremony being performed by Mrs. James Groves, Billingham.

Harbinger.—On August 27th there was launched from the yard of the Sunderland shipbuilding Company (Limited) an iron screw steamer, built to the order of the Harbinger Steamship Company, which is managed by Mr. John L. Browne, John-street, Sunderland. The vessel has short full poop, raised quarterdeck, bridge, and topgallant forecastle, and is of the following dimensions:—270 ft. by 37 ft. by 20 ft. 6 in. with engines of 170-horse power, which are supplied by the North-Eastern Marine Engineering Company (Limited). The vessel is fitted in every detail with the latest improvements for rapid loading and discharging, having special arrangements for the carriage of grain cargoes, and is supplied with four steam winches by Messrs. Clarke, Chapman, & Gurney, Harfield's patent windlass, &c., &c. The vessel was named *Harbinger* by Mrs. Browne, wife of the managing owner.

ON August 27th there was launched from the yard of the Tyne Iron Shipbuilding Company (Limited), of Willington Quay, on Tyne, an iron screw steamer, of the following dimensions, viz.:—Length between perpendiculars, 287 ft.; breadth extreme, 37 ft.; and depth, 23 ft. 6 in. The vessel has been built to the order of Messrs. Joseph Robinson & Co., of North Shields. She is fitted with all modern appliances, including Tyzack's patent anchor.

Raleigh.—On August 27th Messrs. Caird & Purdie, the firm of shipbuilders, who have recently commenced operations at Barrow, launched an iron steamship for Messrs. Holman & Sons, London, and which is intended for the Baltic trade. The new vessel is 245 ft. in length, 34 ft. broad, and has a depth of hold of 17 ft. Her tonnage being about 1,100 tons. Messrs. Westray, Copeland & Co. will supply the engines, and Emerson, Walker & Co. the Patent Windlass. The Company have at present three vessels on the stocks, and trade prospects are very good.

Velasco.—On August 27th the Royal Spanish iron cruiser, *Velasco*, was launched from the yard of the Thames Iron Works and Shipbuilding Company, Blackwall. The vessel is the second iron cruiser built from the same design by this company for the Spanish navy, and similar vessels are now in course of construction in some of the royal dockyards in Spain. She is 210 ft. long, 32 ft. beam, and 16 ft. deep, and 1,039 23-94 tons burthen, British measurement. She will be fitted with engines of 1,500 indicated horse-power by Messrs. Humphreys, Tennant & Co., of Deptford. Her armament will consist of three 6-in. 4 ton breech-loading new type Armstrong guns. The *Velasco* belongs to the type of fast unarmoured cruisers now largely adopted in the principal European navies, which are found useful on distant stations in time of peace, and are specially adapted for the protection of the Commercial Marine in time of war. The ceremony of naming and launching the vessel was performed by Senora De Ojeda, and the launch was perfectly successful.

Abeja.—On September 3rd Messrs. John and William B. Harvey launched from their yard at Littlehampton a wood-built schooner, of the following dimensions:—Length, 100 ft.; beam, 23 ft.; depth, 12 ft.; classed under special survey 13 A 1. She was built to the order of Messrs. Olano Larrinaga & Co., of Liverpool and Bilbao, and is intended for the Philippine Island trade. On leaving the ways the vessel was named the *Abeja*, the christening ceremony being performed by Miss Mary Gales, of Littlehampton.

Maha Vajirunhis.—On September 6th there was launched from the yard of Messrs. C. Mitchell & Co., Low Walker, a screw steamer built for local trade in the East Indies, and, as light draught of water is a consideration, she has been built entirely of steel. The vessel is 250 ft. long, 32 ft. beam, has a full poop, which will be fitted for first-class passengers in a most complete manner, and as the vessel will, as mentioned, be trading in the East, her upper deck with all its fittings are of teak. Immediately after the launch the steamer was taken to the Wallsend Slipway Engineering Company's works, to be there fitted by them with powerful compound engines capable of propelling her at a speed of 12 knots. The vessel, which has been built to the order of Mr. H. Katz, of Singapore, was, on leaving the ways, named the *Maha Vajirunhis* by Mrs. Park, wife of the owner's engineer.

Brunette.—On September 6th was launched from shipbuilding-yard of Messrs. C. S. Swan & Hunter, Wallsend, an iron screw steamer, built for Th. Rodenacker, Esq., of Dantzic, of the following dimensions:—Length, B.P., 202 ft.; breadth extreme, 28 ft. 6 in.; depth of hold, 15 feet 6 in. She is fitted with Patent Cone Brake Windlass—Emerson, Walker & Co.'s Patent. The vessel was named the *Brunette* by Miss Hassell, daughter of G. C. Hassell, Esq., of Newcastle, and proceeded to the crane to receive her machinery of 110 horse-power, by Messrs. Black, Hawthorn & Co., Gateshead.

Gulf of Carpentaria.—On September 8th William Gray & Co. launched from their yard at West Hartlepool an iron screw steamer of the following dimensions:—Length over all, 300 ft.; breadth, 38 ft.; depth to spar deck, 27 ft. 3 in.; classed 100 A 1 Lloyd's; built to the order of the Greenock Steamship Company, Greenock. This vessel is intended for the Australian trade, to carry 3,500 tons deadweight, and has spacious 'tween decks for carrying horses and cattle; and fitted with all recent improvements, including steam steering gear, Napier's steam windlass, steam winches by Messrs. Clarke, Chapman & Gurney, Newcastle. The construction of the vessel is extra strong, beyond Lloyd's requirements, having two additional water-tight bulkheads, and topside strakes doubled. The main and spar decks are of iron, the latter covered with teak, and is double-bottomed, on the cellular system, for water ballast, the entire length of the ship. The engines are to be fitted by Messrs. Blair & Co. (Limited), Stockton, and are of high power, as the vessel is intended to be a fast sailer. On leaving the ways the christening ceremony was performed by Mrs. A. Morris, of Greenock, the vessel being named *Gulf of Carpentaria.*

Baines Hawkins.—On September 9th Messrs. Hodgson & Soulsby, Cowper Quay, Blyth, launched an iron screw steamer for Messrs. Fisher & Renwick, of Newcastle. Her dimensions are:—Length over all, 197 ft.; breadth (extreme), 30 ft.; and depth of hold, 13 ft. 9 in., and to carry 300 tons dead weight. She will be engined by Messrs. Hawks, Crawshaw & Co., of Gateshead, with engines of 90 nominal horse power, with cylinders of 48 in. and 24 in. diameter. She is called the *Baines Hawkins.*

Chrysolite.—On September 10th Messrs. M. Pearse & Co launched from their iron shipbuilding yard at Stockton an iron screw steamer, named the *Chrysolite*, of the following dimensions, viz.:—Length between perpendiculars, 250 ft.; extreme breadth, 34 ft.; depth of hold to top of floors, 22 ft. This vessel is about 1,600 tons gross register, is classed 100 A 1 at Lloyd's, and has been built under special survey. She has a short full poop, long bridge-house amidships, and topgallant forecastle. Her main and upper decks are of iron, and she has double bottom for water ballast, is schooner-rigged, with double topsails on the foremast. She is furnished with four double-cylinder steam winches, steam steering gear, and is replete with all the latest and improved appliances for expeditiously loading and discharging cargoes. The engines for this vessel, which are on the compound direct-acting principle, are of 130-horse power, and from the well-known establishment of Messrs. Blair & Co., of Stockton. The steamer is built for Messrs. W. Talley & Co., of Hull, and is the third of four which the owners have ordered from Messrs. M. Pearse & Co.

Westwood.—On September 10th there was launched from the shipbuilding-yard of Messrs. Robert Thompson & Sons, Southwick, an iron screw steamer, built to the order of David Wilson, Esq., of Hull, of the following dimensions, viz.:—Length, 240 ft.; breadth, 34 ft.; depth of hold, 17 ft. She has been constructed under Lloyd's special survey to class 100 A 1, having long quarter deck extending to after end of bridge, with cabin fitted up under bridge for captain and officers, and accommodation at side of engine-room for engineers and petty officers, also for firemen and crew in topgallant forecastle. Her arrangements and fittings throughout are of the most recent and best, and she is intended to carry a large cargo on medium draught. She is fitted with four steam winches and donkey boiler by Messrs. Clarke, Chapman & Gurney, Gateshead, Harfield's patent windlass, anchor crane, patent midship steering apparatus, patent screw gear aft, &c., &c. The engines for the vessel are being made by Messrs. C. D. Holmes & Co., Hull, and are of 120-horse power. As the vessel left the ways she was named the *Westwood* by Mrs. Laws, wife of Captain Laws, who takes command.

Anerley.—On September 8th there was launched from the shipbuilding yard of Messrs. Blumer & Co., North Dock, Sunderland, an iron screw steamer of the following dimensions:—Length, 270 ft.; breadth, 37 ft.; depth of hold, 24 ft. 6 in. This vessel has been built to the order of Messrs. Watts, Ward, & Co., London and Newcastle-on-Tyne, and is the fourth vessel these builders have built for the same owners. She is of the highest class at Lloyd's, and is being fitted with all the latest improvements. As the vessel left the ways she was christened the *Anerley* by Miss Robinson, of Birmingham.

Wydale.—On September 10th a new steamer named the *Wydale* was launched from the yard of Messrs. John Redhead & Co., at South Shields. Her length is 275 ft., beam 36 ft., and depth 23 ft. She is to carry 2,000 tons deadweight, and will have engines of 185-horse power at 80 lbs. pressure. She will be fitted with Harfield's patent windlass, patent steam steering apparatus, and all other modern appliances. The vessel is intended for the Atlantic and general trades, and the owners are Messrs. Pantland, Hick & Co., of Scarborough.

Mount's Bay.—On September 10th Messrs. Schlesing, Davis & Co. launched from their building-yard at Wallsend a steamer named the *Mount's Bay*. This vessel has been built to the order of the Mount's Bay Steamship Company (Limited), of Penzance, the managers of which are Messrs. F. Banfield & Son. The *Mount's Bay* is a spar-decked vessel of the following dimensions:—Length between perpendiculars, 290 ft.; breadth, 37 ft.; and depth moulded, 28 ft. 6 in. Classes 100 A 1 at Lloyd's, and has been built under special survey. It is estimated she will carry over 3,000 tons deadweight. Her engines are being constructed by Messrs. Black, Hawthorn, & Co., of Gateshead, and are of the compound surface-condensing description, the cylinders being 37 and 70 in. in diameter, with a stroke to each of 45 in. It is calculated this power will drive the vessel at a speed of at least 10 knots an hour. The main deck of the vessel is of iron, and the spar deck of wood. She has four separate holds, the cargo from which will be discharged by four powerful steam winches, to be fitted by Messrs. J. Smith & Sons, of Newcastle. The winches will be worked either by a large donkey boiler or from the main boiler, as may be preferred. The holds have also arrangements by double stanchions from deck to ceiling for dividing the ship longitudinally to adapt her for carrying grain in bulk. The water ballast tanks are under the fore, main, and after holds, and will contain sufficient water to enable the vessel to steam with holds quite empty. One of Messrs. Donkin and Nichol's steam steering gears will be fitted on the bridge, and a powerful screw gear aft. The cabin arrangements for passengers and officers are aft. One of Harfield's patent steam windlasses is supplied for working the anchors and cables. On the vessel leaving the ways the ceremony of naming her was performed by Mrs. John Canfield.

Westergate.—On September 12th Messrs. Short Brothers launched from their yard at Pallion, Sunderland, a screw steamer of the following dimensions, built to the order of Messrs. Weatherley, Mead, and Hussey, London:—Length between perpendiculars, 260 ft; breadth, 36 ft.; and 20 ft. depth of hold, with a deadweight carrying capacity of about 2,450 tons. She is classed 100 A 1 Lloyd's Register, and is constructed with a short full poop for accommodation of officers, raised quarter deck from poop to bridge, bridgehouse amidships, and topgallant forecastle for accommodation of crew; water ballast in main and after holds and peaks; four steam winches and donkey boiler, by Clarke, Chapman, and Gurney, Gateshead; Harfield's windlass; Bow, M'Lachlan, & Co.'s steam steering gear, and all the latest improvements. On leaving the ways, the vessel was named the *Westergate*, the ceremony of christening being performed by Miss Fowler, daughte of Captain Fowler, who will take command. The vessel was taken in tow for Hartlepool, where she is to be fitted with engines of 160-horse power by Messrs. Thomas Richardson & Sons, with all their latest improvements in marine engineering.

Marima.—On September 21st Messrs. Edward Withy & Co. launched from Middleton Shipyard, West Hartlepool, an iron screw steamer built for Messrs. Steel, Young & Co., of London and West Hartlepool. This vessel is No. 100 in the builders' books, and is the 18th steamer they have built for the same owners. Her principal dimensions are:—Length by perpendiculars, 257 ft. 6 in.; beam extreme, 34 ft. 6 in.; depth, moulded, 20 feet 4½ inches. She has topgallant fore-castle, bridge house, long quarter-deck, and a short poop over the cabin; has double bottom all fore and aft for water ballast, constructed on the cellular system. The decks, chart-house, engine skylight, cabin companion and skylight, as also the main rail, are built of iron. She will be fitted with four steam winches, donkey boiler, and Emerson, Walker & Co.'s patent windlass, and will be rigged as a double topsail schooner. She has been built under Lloyd's special survey for the 100 A 1 class, and will be fitted with engines of 150-horse power by Messrs. T. Richardson & Sons, of Hartlepool Iron Works. On leaving the ways the steamer was christened *Marima* by Miss Forster, of Darlington.

St. Ronan.—On September 21st a steamer was launched by Earl's Shipbuilding Company from their building yard at Hull. She is intended for the Atlantic cattle and grain trade, and is built for Messrs. Rankin, Gilmour & Co., Liverpool. She was named the *St. Ronan*, and is of the following dimensions:—Length, 402 ft.; breadth, 43 ft.; depth, 34 ft.; gross tonnage, 4,600 deadweight; capacity, 5,000 tons. She is an awning-decked ship, and is built even of greater strength than the A 1 Lloyd's Rules require. She will be propelled by engines of 500-horse power nominal, and expected to develop 2,400 tons, which will drive the ship 12 knots Steam is supplied by three large steel boilers.

Ada.—On the afternoon of September 26th there was successfully launched from the ship-building yard of Messrs. Robert Thompson & Sons, Southwick, an iron screw-steamer named the *Ada*, built to the order of Messrs. Turner, Edwards & Co., of Bristol, of the following dimensions, viz.:—Length, 220 ft. breadth, 30 ft., and depth, 15½ ft. She has been constructed under Lloyd's Special Survey to class 100 A 1, having a long quarter-deck, short, full poop, with accommodation for captain and officers, top-gallant and forecastle for crew, and short bridge amidships for engineers. Her arrangements and fittings throughout are of the most recent, and she is built on the web frame and shelf plate system in hold, instead of hold-beams for the stowage of cargo; and on the cellular bottom principle, with plate steel. She is fitted with steam winches and donkey-boiler by Messrs. R. Roger & Co., Stockton, Harfield's patent windlass, anchor crane, patent midship steering apparatus, patent screw-gear aft, &c. She will be fitted with engines of 90 nominal horse-power by Mr. George Clark, of Southwick.

LAUNCHES.—SCOTCH.

Lamington.—On August 23rd there was launched from the yard of Messrs. Robert Duncan & Co., Port Glasgow, a screw-steamer of about 2,000 tons gross register, and 3,000 tons dead weight capacity for the firm of Messrs. Renton & Co., Glasgow, for general trading purposes. Dimensions 275 by 37 by 23, classed 100 A 1 at Lloyd's, and 20 years in red in Liverpool Register. This vessel has been specially designed for a cargo boat, and has accommodation for a small number of passengers. She has been built of great strength, with double bottom on the cellular principle fore and aft, and is one of the first vessels of her particular type constructed on the Clyde. She was named *Lamington* by Mrs. Renton, wife of the Managing Owner, and immediately after the launch was towed to Greenock to receive her engines of 200 nominal horse power, from the firm of Messrs. Rankine & Blackmore. On completion, she will proceed to London and be loaded for Adelaide, Melbourne, and Sydney, by Messrs. W. Gracie & Co., and Messrs. Ismay, Imrie, & Co. The steamer will be commanded by Captain F. L. Burkill, late of the *Lindores Abbey*, belonging to the same firm.

Prins Alexander.—On August 24th a screw steamer of 3.100 tons, was launched by Messrs. John Elder & Co., at Fair field. Her principal dimensions are as follow:—Length between perpendiculars, 350 ft.; breadth 32 ft.; depth, moulded, 30 ft. 9 in. Miss Vichoff, of Paris, named the vessel *Prins Alexander.*

Pen Douran.—On August 25th Messrs. Henry Murray & Co. launched from their Kingston yard a four-masted iron sailing barque of about 1,900 tons register. Her dimensions are:—Length between perpendiculars, 270 ft.; breadth of beam moulded, 40 ft.; depth of hold from the top of ceiling, 23 ft. 8 in.; and she classes in Lloyd's highest grade. She is fitted with Emerson, Walker & Co.'s patent double-purchase Capstan windlass, and built for the Ben Line, of which Messrs. Watson Bros., of Glasgow, are the owners. The vessel was named the *Ben Douran* by Miss Bessie Watson, daughter of John E. Watson, Esq. After completing her outfit in Port-Glasgow Harbour she will load coal there for San Francisco.

Mindanao.—On August 26th Messrs. H. M'Intyre & Co. launched from their shipbuilding yard at Merksworth, near Paisley, an awning-deck screw-steamer of 1,200 tons gross register. She is built for Captain William Watt, of Helensburgh, and is intended for local trade in the East. She will be fitted with a pair of engines of 700 indicated horse-power by Messrs. Hutson & Corbett, of Glasgow. As she left the ways she was named the *Mindanao* by Mrs. Watt, wife of the owner.

Marquis de Valuma.—On August 27th there was launched from the shipbuilding yard of Messrs. D. Allan & Co., at Caroline Park, Granton, this vessel, the dimensions of which are 92 ft. in length, 17 ft. 6 in. in breadth, and 8 ft. 6 in. in depth. She is another of the fleet which is being built for the Spanish Fishing Company in Madrid. The engines of this steamer have been supplied by Messrs. Walker, Henderson & Co., Glasgow, and are of the newest compound principle. The steam trawling, which is a new industry in Spain, is now being rapidly developed. A vessel of larger dimensions is now being built by Mr. Allan for the Forth Fishing Company. The steam trawling in the Firth of Forth is now being greatly increased, and is superseding the old system of fishing. During the past few months these trawlers have been paying fully 50 per cent. It is believed that in a few years trawling will entirely supersede the line fishing.

Craignair.—On August 27th Messrs. Dobson & Charles launched from their shipbuilding yard, at Grangemouth, an iron screw steamer, built to the order of Messrs. T. Biggar & Sons, Dalbeattie, of 170 tons, and of the following dimensions:—90 by 18 by 8. She will be supplied with engines of 30-horse power by Messrs. R. H. Pearson & Co., Glasgow. As she left the ways the ceremony of naming her the *Craignair* was performed by Miss M. Alley, Falkirk.

India.—On August 27th Messrs. Wm. Denny & Brothers launched from their shipyard at Dumbarton a steel screw steamship of the following builders' dimensions:—390 by 42 by 31, and of about 4,100 tons gross, for the British India Steam Navigation Company. She has been built to class 100 A 1 at Lloyd's, under special survey, and is to be fitted with a pair of compound surface-condensing direct-acting inverted cylinder engines, of 495-horse power nominal, by Messrs. Denny & Co., Dumbarton. She is fitted for a large number of first-class passengers, with all the comforts usual in first-class passenger steamers. As the steamer left the ways she was named the *India* by Miss Sarah M'Naughton, daughter of J. M'Naughton, Esq., Secretary of the British India Steam Navigation Company.

Condor.—On August 27th Messrs. Dobie & Co. launched from the Govan Shipbuilding yard an iron screw-steamer, built by them for the Cork Steamship Company (Limited), of Cork, to the highest class, and measuring about 1,100 tons gross. As she left the ways she was named *Condor* by Mrs. Young, Newstead-house. The engines are being supplied by Messrs. James Jack & Co., engineers, Liverpool, and direct-steam windlass by Emerson, Walker & Co., patentees, London.

Bengore Head.—On August 25th an iron screw steamer, named the *Bengore Head*, was launched from the shipbuilding yard of Messrs. A. & J. Inglis, Point-house, Glasgow. . The steamer is for Belfast owners, having been built to the order of the Ulster Steamship Company (Limited), of which Messrs. G. Heyn & Sons, Ulster-chambers, Belfast, are the managers, and will be engaged in the American, Eastern, and other long-voyage trades. The dimensions of the *Bengore Head* are:—Length, 352 ft.; breadth, 40 ft.; and depth, from top of ordinary floors to spar deck, 32 ft. 1 in.; about 3,386 tons gross, and 2,210 tons nett register; with a total carrying capacity of about 4,900 tons. The engines, to be supplied by the same firm, are on the compound surface-condensing principle, with all the latest improvements; cylinders 40 and 77 in., with 54-in. stroke; 400 nominal horse-power. Steam will be supplied from two large double-ended steel boilers, with large heating surface, and of superior construction for a working pressure of 85 lbs.; also, a large auxiliary boiler, to be used in conjunction with the main boilers, or separately, for driving winches, &c., in port. The hull is built to Lloyd's 100 A 1 class, spar deck rules, with extra heavy scantling, upon the longitudinal bracket system, having a double bottom extending fore and aft, fitted for 700 tons water ballast in four compartments, with extra strengthening throughout. There are three iron decks laid, the upper one covered with wood, flush upper deck, with substantial shelter house 80 ft. long amidships, completely protecting engine-room skylights, gratings, and houses. The accommodation for crew is forward, engineers amidships, and captain, officers, &c., in cabin aft. The steamer will be schooner-rigged, with two masts, has five large hatchways, and will be fitted with steam steering gear, steam windlass, five powerful steam winches, and other facilities for the rapid loading and discharge of cargo. The ceremony of naming the ship was performed by Miss M'Dowell, niece of Mr. Alexander M'Laine, the chairman of the company. The steamer will receive her outfit and machinery at the yard of the builders, and was expected to be ready for sea before the end of September. The *Bengore Head* will be the largest vessel registered and owned at the port of Belfast, and is a valuable addition to the Head Line of the Ulster Steamship Company. She will be commanded by Captain Thomas M'Calmont, late of the *Black Head* (s), belonging to the same owners.

Cameo.—On August 31st Messrs. Alex. Stephen & Sons launched from their yard at Linthouse, Govan, an iron screw steamer of about 2,400 tons, classed 100 A 1 at Lloyd's, and built for Messrs. Tellefsen, Wills, & Co., Cardiff. This vessel is fitted with Emerson, Walker & Co.'s Patent Windlass, steam steering gear and every appliance for convenience and efficiency in working the ship and cargo. The engines (also made by Messrs. Stephen) have cylinders 35 and 65 in. diameter by 42 in. stroke, and a working pressure of 80 lbs. The vessel was named the *Cameo* by Miss Stephen, of Broughtyferry.

St. Andrew.—On September 1st the *St. Andrew* (s), another of the steamers building for the Channel Line (Murray Brothers & Co., managers) by the London and Glasgow Shipbuilding and Engineering Company (Limited), was launched from their building-yard at Govan. The vessel is about 600 tons builders' measurement, with compound condensing engines of 100-horse power, and is intended to carry on the trade along with her sister ship the *St. George*, between Glasgow and London, *via* Littlehampton, calling at Greenock, Larne and Dublin. The ceremony of naming the vessel was performed by Miss Mary Bruce Murray. The *St. Andrew* is expected to be ready for the berth in three weeks, and regular weekly sailings will thereafter be maintained.

Opal.—On September 7th there was launched from the ship-building-yard of Mr. W. B. Thomson, Dundee, an iron screw steamer named the *Opal*. Her dimensions are as follows:—Length, 218 ft.; breadth, 30 ft.; depth of hold, 15 ft. 6 in.; gross tonnage, 1,126; horse power of engines, 110. The *Opal* (s) will be under the management of Mr. P. M. Duncan, of Dundee, and will be commanded by Captain Douglas, formerly of the *Amethyst*. She is intended for the Baltic and Mediterranean trades.

City of Calcutta.—On September 8th Messrs. Charles Connell & Co. launched from their yard at Scotstoun the *City of Calcutta*, an iron screw steamer of 3,900 tons gross. This, the latest addition to Messrs. George Smith & Sons' City Line of steamers, is also their largest vessel, and has been built with a number of extras beyond Lloyd's requirements for their highest class. The accommodation for saloon passengers is provided in a large deckhouse amidships, occupying the whole width of the vessel before the engine-room, the crew being accommodated aft below the upper deck. All the latest improvements have been fitted on board for discharging and loading cargo. The new steamer is 400 ft. long, 42 ft. broad, and 31 ft. deep, and when completed her engines are expected to develop a high rate of speed. She is the first of three new steamers for the line to replace three lately sold, which were found to be too small for Messrs. Smith's Calcutta trade. The other two, of somewhat similar dimensions, are under construction in the yards of Messrs. Barclay, Curle & Co., and Messrs. Workman & Clarke, Belfast. As she left the ways she was named by the wife of Captain Robertson, who is to command the vessel.

Heather Bell.—On September 8th, Messrs. T. B. Seath & Co., Rutherglen, launched an iron steam yacht of 300 tons burthen for Mr. H. Robertson Washley, of Peterborough. The vessel was named *Heather Bell* by Miss A. M. Seath.

Loch Moidart.—On September 8th there was launched from the shipbuilding yard of Messrs. Barclay, Curle & Co., Whiteinch, a four-masted sailing ship of 2,000 tons register and 3,500 tons deadweight carrying power, for the General Shipping Company, managed by Messrs. Aitken, Lilburn & Co. She was, on leaving the ways, named the *Loch Moidart* by Mrs. James Arthur, of Barshaw, wife of one of the owners. She is launched for the California and Calcutta trades, has been built to the highest class at Lloyd's, with all the most modern improvements.

Victoria.—On September 9th, Messrs. Aitken & Mansel launched from their Whiteinch yard a saloon paddle-steamer, 190 by 25 by 9. This vessel, which was named *Victoria*, is built of steel, and is completed in the best style for passenger accommodation. She is owned conjointly by the London and South Western and the London, Brighton, and South Coast Railway Companies, and will be employed chiefly in their passenger service between Portsmouth, Ryde and Stoke's Bay. The engines are being fitted by Mr. David Rowan, of Glasgow, and are adapted to obtain a high speed. This vessel has been constructed by the joint companies to secure a more expeditious service for their passenger trade to the Isle of Wight.

Banner.—On September 9th an iron screw steamer of 353 tons and 55 horse-power, built for the coasting and Channel trade, and named *Banner*, was launched by Messrs. John Fullerton & Co., at their yard, Merksworth, Paisley. She is for James R. Currie, Esq., Paisley.

Lake Huron.—On September 10th a new Beaver Liner was launched from the shipbuilding yard of the London and Glasgow Engineering and Iron Shipbuilding Company at Govan. The vessel was named the *Lake Huron* by Miss Winnie Rintoul, of Langbank, and is a screw steamer of over 4,000 tons, being the fourth steamer built by the same firm for the Canada Shipping Company, Limited (Beaver Line). She is 385 ft. long by 42 ft. 6 in. beam by 31 ft. 6 in. to spar deck, and is classed 100 A 1 (three decks) at Lloyd's. She is fitted with steam steering gear, steam winches and windlass; while all other modern improvements have been introduced. The engines are compound surface-condensing of the most improved description, and are 3,000-horse power indicated. The Canada Shipping Company were amongst the first engaged in the cattle-carrying trade between this country and Canada and the United States. This ship has been fitted up specially for this trade, combining all the improvements that the experience of the company have gathered during the last few years. Special attention has also been exercised in the ship's fittings in order to adapt her for the increasing emigrant trade between this country and Canada and the United States, everything having been done to contribute to the comfort, convenience and safety of this class of passengers.

Closeburn.—On September 10th Messrs. Russell & Co., Greenock, launched an iron barque named the *Closeburn*, after the model of the *Peebleshire*, and of the following dimensions:—Length, 200 ft.; breadth of beam, 32 ft. 6 in; depth of hold, 19 ft. 6 in.; of 900 tons register, and to carry about 1,480 tons deadweight. The *Closeburn* has been built for Messrs. Macdonald, Hood & Co., Glasgow, and is intended for the Sydney trade.

Solway.—On September 20th Messrs. Barclay, Curle, & Co. launched from their shipbuilding yard at Whiteinch a new steamer named the *Solway*, for Messrs William Sloan & Co., to be employed by them in the passenger and cargo trade between the Clyde and the Bristol Channel. The new vessel is 220 ft. long, 30 ft. broad, and 15 ft. 3 in. deep. She has been fitted up with many of the latest improvements, including water ballast in three separate tanks, and has the highest classification at Lloyd's. She is to be schooner rigged, and fitted with a pair of surface-condensing compound engines to drive her at a good rate of speed. She will also be fitted with Napier's patent steam windlass, Bow & M'Lachlan's steam-steering gear, three steam winches, and a couple of steam cranes by Muir & Caldwell. The ceremony of naming her the *Solway* was performed by Miss Sloan.

Ossian.—On September 21st Messrs. H. M'Intyre & Co. launched from their shipbuilding-yard at Paisley, the *Ossian*, an iron screw steamer of 800 tons. The *Ossian*, which has been built by the London and Edinburgh Shipping Company, is classed 100 A 1 at Lloyd's, and fitted up as a first-class cargo steamer. The engineers are Messrs. Hutson & Corbett, Glasgow. The ceremony of naming was performed by Miss Helen Madeline Usher, of Edinburgh.

Valdivia.—On September 22nd Messrs. John Reid & Co., Greenock, launched a steel barque named the *Valdivia*, of 900 tons. The *Valdivia* is a sister ship to the *Bolivia*, launched about a month ago by the same firm, both vessels having been built for Messrs. Nicolson & M'Gill, Liverpool.

Benlarig.—On September 22nd Messrs. Alexander Stephen & Son launched from their yard at Linthouse, an iron screw steamer of the dimensions 310 by 38 by 25, built under special survey to highest class in Lloyd's, and named the *Benlarig* by Mrs. Mitchell, wife of Lieutenant-Colonel Mitchell, Tillicoultry House. This is the second steamer built by Messrs. Stephen to the order of Messrs. Wm. Thomson & Co., Leith, for their Ben Line of London and China clippers. Her engines, which are also of Messrs. Stephen's construction, and were fitted on board before launching, are on the compound surface-condensing principle, and of 300-horse power nominal, the boilers being very ample, and suitable for working at 85 lbs. pressure.

Lamprey.—On September 22nd Messrs. Blackwood & Gordon, Greenock, launched from their yard a screw steamer of the following dimensions:—Length, 155 ft.; breadth of beam, 24 ft.; depth of hold, 14 ft. This steamer, which was named the *Lamprey*, has been built for Mr. John Burns, and is to be engaged in the passenger trade between Larne and Greenock.

LAUNCH.—French.

La Ville de San-Nicolas.—On August 18th there was launched from the shipbuilding yard of Forges and Chantiers de la Mediterranée at La Seyne (Var), under the experienced management of Mr. Lagane, an iron screw steamer built for the "Compagnie des Chargeurs Réunis du Hâvre." The dimensions are:—Length between perpendiculars, 294 ft.; breadth moulded, 35 ft.; depth moulded, 25 ft.; tonnage nett registered, 1400 tons. She will carry about 3000 tons deadweight, and is classed at the highest class of Bureau Veritas, under special survey. She will be provided with direct-acting inverted compound engines of 1000 indicated horse-power by the same firm at La Seyne. She will be fitted with double bottom for water ballast, four steam winches, and all the most recent and improved appliances for expeditious loading and discharging cargoes, patent windlass and patent steam steering gear. In addition to superior cargo space for the conveyance of general goods, the vessel will be able to accommodate in tween-decks, 460 emigrants. She has been christened *La Ville de San-Nicolas* as she left the ways. She will form the second of a fleet of five screw-steamers ordered by the same firm at Havre—the first one, christened *La Ville de Rosario*, and launched July 16th, is nearly ready for her trial trip.

TRIAL TRIPS.

Westport.—Previous to sailing for New Zealand, this steamer went down the Clyde on a trial trip. She is a vessel of 500 tons burthen, 155 ft. long, 22 ft. beam, and 11 ft. depth of hold. She is 420-i.h.p., and she ran the lights at a mean speed of 11 knots per hour. The *Westport* was built to the order of Captain Williams, coal merchant, Wellington, New Zealand, by Messrs. Murdoch and Murray. She was engined by Messrs. Muir and Houston, Glasgow. The *Westport* is a sister ship to the *Romeo* (s.), which left Glasgow last year for Manila, and is fitted up for 20 first-class, 32 second, and a like number of steerage passengers. She is equipped with all the latest improvements both as to gearing and the securing of comforts to the passengers.

Tempo.—On August 27th the screw-steamer *Tempo*, of Newcastle, was taken to sea for official trial. The *Tempo* was built by Messrs. T. and W. Smith, North Shields, and launched from their yard in July. The vessel is owned by Messrs. Fenwick and Reay. Her dimensions are 230 ft. by 35 ft. by 17 ft., and her engine power will be 120-horse power nominal. She has water-ballast tanks, and her arrangements on deck combine all the latest improvements for rapid loading and quick discharging. To further this end her hatches have been specially arranged so that cargo can be taken from two ordinary spouts simultaneously. Messrs. Hawkes, Crawshay & Co. put her engines in at their Gateshead works. The *Tempo* also has Donkin's and Nicholls' patent steam steering gear, in addition to the hand wheel. She is destined chiefly for the Baltic and coasting trades, and left for Stockholm, after the trial, with a cargo of coals. The trial was a most satisfactory one. There was a rather heavy sea on, and the owners, who were on board, were enabled to test the sea-going qualities of their vessel, on the measured mile, against a strong head sea and tide. A mean speed of 10 knots per hour was obtained.

Pacha.—On August 31st the steamer *Pacha*, recently purchased by Mr. Robert Taylor, left the Dundee Harbour on a trial trip. The vessel was for several years employed in carrying goods and passengers between Hull and Hamburg, and has been acquired by Mr. Taylor as a general cargo boat, and has undergone extensive alterations. All the holds have been refitted, the engines and boilers have been carefully overhauled, and the ship has been re-classed at Lloyd's. Before returning to Dundee the speed was tested by the measured mile, and was found to be at the rate of 9½ knots per hour. Captain Easson has received the command of the ship.

Portugal.—On September 1st, the steamer *Portugal*, which has been built to the order of the Empreza Nacional, of Lisbon, by Earle's Shipbuilding and Engineering Company, was put upon her official trial. This vessel is intended to trade between Lisbon and the West Coast of Africa, carrying mails and passengers. A trial of speed by the patent log gave 12 knots per hour. The dimensions of the *Portugal* are—length 291 ft., breadth of beam 35 ft., depth of hold 25 ft. 6 in., gross carrying capacity 1,966 tons. The vessel is brig rigged, and will be able to carry a large spread of canvas. She is steered by steam gear, situated in deckhouse amidships, the gear in use being Bow and McLachlan's, of Paisley. There is also in the steering-house a hand wheel, which is always connected, and Skinner's patent hand steering gear which can be almost instantaneously connected. The passenger accommodation is as follows: Saloon, 60 passengers; second-class, 32; third-class, 120. The *Portugal* is partially a double-bottom and partially a tank ship, and she carries 400 tons of water ballast, whilst her bunkers hold 360 tons of coal. She is propelled by engines of 220-horse power nominal, and on the trial trip, with sixty-two revolutions they indicated 1,342-horse power.

Waverley.—On September 1st, this vessel, recently launched by Messrs. Gourlay Brothers & Company, Dundee, for Messrs. Williamson, Milligan & Company, Liverpool, went. on a trial trip. When she got to the Buoy of Tay she ran the distance from there to the Bell rock. From thence she proceeded in the direction of Anstruther. The run was continued to Elie, and there the homeward voyage was begun. On the way the *Waverley* again ran the distance between the Bell Rock and the Buoy. The average speed was 13¼ knots. The *Waverley*, which is a ship of 3,000 tons, is provided with Emerson, Walker and Company's Patent Direct Steam Capstan Windlass and every modern improvement. She sailed for London, and there loads for the Cape.

Rome (s.s.)—The magnificent steamer *Rome* is one of the latest additions to the fleet of the Peninsular and Oriental Steam Navigation Company. She has been built by Messrs. Caird & Co., Greenock, who have for a long time built steamers for the company. The *Rome* was launched on the 14th of May last from Messrs. Caird's yard. She is 430 ft. long, 44 ft. broad, and 36 ft. deep, with engines of 5,100-horse power indicated. The vessel has been specially built with a view to meet the rapidly developing trade between this country and Australia. She will be able to carry about 4,000 tons cargo. She is excellently fitted up all over, and the walls of the saloon and music room inlaid with carved walnut from Italy. There is accommodation for 160 first-class passengers, whose quarters are, contrary to the usual custom, situated amidships and forward. Fifty second-class passengers will be accommodated at the stern. The vessel is practically a four-decker, having hurricane deck, upper deck, main deck, and lower deck. She is divided into seven water-tight compartments, and is provided with an extra large number of powerful pumps. The crank-shaft, which is of Vickers steel, weighs 30 tons. All the most modern appliances for the rapid loading and discharging of cargoes have been fitted. On September 3rd the *Rome* took a preliminary trip down the Firth of Clyde as far as Brodick Bay. There was a distinguished party of ladies and gentlemen on board, including Mr. Sutherland, chairman and manager of the company. The engines worked in a satisfactory manner. The *Rome* will proceed to London shortly, and she will start on her maiden voyage for Australia early in October. On her official trial she attained a mean speed of 15 knots, which was considered highly satisfactory by all concerned, especially as she has not been docked since launched four months ago.

Ville de Naples.—This steamship, 1,900 tons, built and engined by J. & A. Inglais, Pointhouse, for the mail and passenger service of the Compagnie Generale Transatlantique, in the Mediterranean, went down on the Clyde on September 7th, for the purpose of adjusting compasses and running the usual trial trip before proceeding to her distination. The *Ville de Naples* has been furnished with every modern improvement, her interior being fitted up in a superior manner for the comfort of both passengers and crew.

Thetford.—The trial trip of this screw steamer, which was launched a few weeks ago from the yard of Mr. R. Thompson, Southwick, to the order of Messrs. Thompson and Wrightson, of the Standard Steamship Company (Limited), Sunderland, took place on the 8th inst., under favourable circumstances. In length the *Thetford* is 248 ft. between perpendiculars, in breadth 34 ft., and in depth 17 ft. Her decks are all of iron, with the exception of the small poop, which is of wood. All the best and latest improvements in the equipment of merchant steamers have been utilised, four large hatches being provided, in order that cargo may be loaded rapidly and economically, while the vessel is specially adapted for carrying grain in bulk. Each hatchway is supplied with a powerful steam crane by Messrs. Clarke, Chapman & Gurney, of Gateshead. The engines are on the compound surface-condensing principle, and were supplied by Messrs. G. Clark, Southwick. The cylinders are 31 in. and 57 in. respectively, with a 36-in. stroke, working up to 80 lbs. pressure, and indicating 750-horse power. All being in readiness, the steamer's head was turned northward, in order to have a trial of speed over the measured mile off the Northumberland coast. The engines were found to be working most satisfactorily, and averaged during the trial 9½ knots per hour against wind and tide, the vessel having on board 1,900 tons of cargo.

Malabar.—The Indian troopship *Malabar*, Captain Grant, made a two hours' trial of her machinery September 9th in the Solent after repairs, and preparatory to her departure for Bombay. The trial was conducted by Mr. Charles Icely, Chief Inspector of Machinery, belonging to the Steam Reserve, and Mr. Morcom, of the Dockyard Steam Department, and there was a great number of ladies and gentlemen on board. The pressure in the boilers averaged 45 lbs. to the square inch, which was considerably within their working power, and with 48 revolutions of the engines per minute the ship realized the highly satisfactory speed of 13·2 knots per hour, with her full quantity of coal in the bunkers. The mean vacuum was 27 in. Since the previous trooping season the *Malabar* has been fitted with steam steering gear, and with remarkably good results, as the following comparative *data* of tests made by Mr. Crocker during the trial will show:—The ship was circled to starboard and port with steam and with the usual hand gear, one man sufficing to steer the ship with the former, while 16 men were required to man the wheel. With the steam gear the angles of rudder were 34 deg. and 32 deg. for starboard and port helm respectively, while with the manual gear the angles were 31 deg. and 33 deg., three and-a-half turns of the wheel being required in both cases. The difference in time required to get the rudder over under the two systems was very marked, and had an important result in the comparative handiness of the ship in going round and in the respective diameters of the circles. With the steam gear the rudder was got over in 15 sec. and 14 sec., whereas it took 2 min. 15 sec. and 2 min. 5 sec. to accomplish the same angle by hand. Under the new system the complete circles to starboard and port were made in 6 min. 14 sec. and 6 min. 40 sec., the respective diameters being 674 and 702 yards. By hand the rudder was got over in 6 min. 35 sec. and 7 min. 4 sec.; and as in the latter case the ship felt the bite of the rudder more gradually, the diameters of the circles were found to be 814 and 843 yards. At the conclusion of the trial the *Malabar* was swung for the adjustment of her compasses, and afterwards returned into harbour.

Clyde.—On September 13th the Peninsular and Oriental Steam Navigation Company's steamer *Clyde*, built and engined by Messrs.

Denny Brothers, of Dumbarton, of 4,100 tons register, went her trial on the Clyde, and attained a mean speed of 15·9 knots (equal to 18¼ miles per hour), the horse-power indicated being 4,900. This vessel is fitted with all the recent improvements. The *Clyde* will be despatched from London to Calcutta on October 11th.

Charkieh.—The *Egyptian Gazette* of the 17th ult. says :—The trial trip of the (s.s.) *Charkieh*, which lately took place, was, thanks to Mr. Caillard and the other members of the Poste Khedivieh Administration, made the occasion of a most agreeable day's holiday for many Alexandrians. The *Charkieh* is a smart-looking steamer, built by the Thames Iron Works Company in 1865. She is 267 ft. in length with 36 ft. 8 in. beam, and measures 1160 tons register. Originally the property of the old Azizieh Company, she was purchased by the Egyptian Government for L.E. 23,289. In 1872 she was sent to England to receive new boilers and undergo a thorough overhaul. These operations occupied fifteen months, and cost no less than L.E. 39,302. On her return to Egypt, with the exception of a short interval during the Turco-Russian war, when the *Charkieh* was employed in the transport of troops, she ran regularly with the mails between Alexandria and Constantinople, until November, 1879, when her boilers having given out, she was withdrawn from the service and laid up in the port of Alexandria. Her present engines are by Messrs. James Jack & Co., of Liverpool—Allen, Anderson & Co., Alexandria—a firm which has constructed several of the engines of the steamers belonging to the Moss line. The new compound surface condensing engines of the *Charkieh*, are of 1500 indicated horse-power, with boilers tested to 140 lb. to the square inch, to work at a pressure of 70 lb. to the square inch. The price of the engines and boilers delivered in Alexandria was £10,500.

Cameo.—On September 21st the steamship *Cameo*, built and engined by Messrs. Alex Stephen and Sons, Linthouse, Glasgow, for Messrs. Tellefsen, Wills & Co., Cardiff, ran her trial trip. The *Cameo* is intended for the general carrying trade, for which she is designed and equipped. Her dimensions are 300 by 39 by 25.4, with a double bottom for water ballast, on the bracket principle throughout. She has a full poop, containing saloon, captain's room, and a number of state rooms; the officers and crew being accommodated in houses amidships and a topgallant forecastle. The midship steering gear can be worked by either steam-power or hand at will. The after steering gear, the windlass, and other appliances for working the ship, are all of the most complete and most approved description, while those for working cargo are very ample and efficient, including powerful steam winches, &c., and the water-tanks are supplemented by provision for distilling and condensing 600 gallons of fresh water per day. The engines are of Messrs. Stephen's usual type, on the compound surface-condensing principle, having cylinders 35 and 65 in. diameter by 42 in. stroke, with large boilers, constructed to work at 80 lbs. pressure. At the trial everything worked with the utmost smoothness, and to the entire satisfaction of all on board. On the measured mile the steamer averaged 11½ knots. The *Cameo* is to be registered in Cardiff, and is constructed to carry 3,600 tons dead weight, with a freeboard of 2½ in. to the ft. of depth of hold.

Lesseps.—On September 21st there proceeded to sea from the yard of Messrs. Raylton, Dixon & Co., her builders, an iron screw-steamer, named the *Lesseps*, built to the order of Herr Jacob Christensen, of Bergen. Her dimensions are :—270 ft. long by 34 ft. 9 in. breadth of beam, and 24 ft. 7 in. depth of hold, and her burthen is about 2,600 tons, on 22 ft. draught. She is built on the three-decked rule, having upper and main decks laid, the latter of iron. Water ballast in a large chamber in mainhold forward of the engine-room. In a full poop aft are placed commodious cabins for the captain, chief officer, and two or three spare berths. She is fitted with steam steering gear on bridge house on deck, steam winches, patent self-reefing topsails, and all the latest improvements for a vessel of her class. Her engines, of 150-horse power nominal, are by Messrs. Blair & Co., of Stockton, and gave every satisfaction on her trial trip round to the Tyne.

Thyra (s.s.).—On the 13th of September the new screw-steamer *Thyra*, built by the Flensburg Iron Shipbuilding Company, made her trial trip in the Bay. She is a very handsome boat, built on the "spar decked" principle. Dimensions: Length, between perpendicular, 212 ft.; breadth extreme, 29 ft. 8 in.; depth of hold, 22 ft.; gross tonage, 1,036, and will carry about 1,200 tons dead weight. Her cabins for the accommodation of captain, officers, and a few passengers are below the spar deck amidships on the fore side of the engine-room, the entrance to which is protected by an elegant companion-house, which adjoins the chart-house, and is built of teak. In the two wing-houses under the pilot-bridge are fitted store, scullery, lamp rooms, &c. The engineers are accommodated on the afterside of the engine-room, under the spar deck, with entrance direct to the engine-room platform. This vessel is so arranged that in her light draught she is about 12 in. by the stern, as are most of the "spar decked steamers" built by this firm. The vessel is fitted with steam windlass, and three winches of the latest improvement; her deck has a very neat look, all skylights, companions, also binnacles and rail, &c., being made of prime "East India Teakwood;" the cabin is kept in a very fine style, and is made in French polished hardwood (mahogany and maple.) The engines, which are also built by the Flensburg Shipbuilding Company, are of 100-horse power nominal on the compound surface condensing principle. A large party, consisting of shareholders and builders, proceeded with her on her trial trip, which was very satisfactory, an average speed of 10 knots per hour being obtained with a consumption of 8 tons of coal per 24 hours. The (s.s.) *Thyra*, which is the fifth vessel built by the above-named company for Messrs. Bruhn & Co., is destined for the trade on the China coast, where she will proceed directly after her trial trip.

Torpedo Boats.—On August 31st trial was made of a torpedo boat built by Messrs. Yarrow & Co., in the presence of the Austrian authorities to test the consumption of fuel when running at a comparatively slow speed, in order to ascertain the distance such a boat can run at sea without putting in for a fresh supply of fuel. The dimensions of the boat are 100 ft. in length by 12½ ft. beam. The trial was made of four hours' continuous steaming at a speed of 11 statute miles an hour, and the exact consumption was found to be 196 lb. of Welsh coal per hour, which is equivalent to 8 tons of coal per 1,000 miles, and as such a vessel can carry 10 tons, torpedo boats of this size and description will be capable of steaming a distance of 1,200 miles without a fresh supply of fuel.

ON September 18th a trial took place of one of two sea-going torpedo boats built for the Austro-Hungarian Government by Messrs. Yarrow & Co., of Poplar. The run was made over the measured mile at Long Reach, in the presence of Count Cassini, naval attaché, and the chief officials of the constructive and engineering departments at Pola. The vessel in question is of the same dimensions and type as the *Batoum*, built last year by the same firm for the Russian Government, but in many respects considerably superior. Her dimensions are 100 ft. in length by 12½ ft. beam. This class of boat, as built by Messrs. Yarrow & Co., has been proved to be thoroughly sea-going. The *Batoum* steamed from London to the Black Sea. Two similar boats were built for the Argentine Government, one of which steamed round to Fiume and the other is now crossing the Atlantic. Six Greek boats, also of the same dimensions, have safely arrived in Greece. The engines are of the compound surface condensing type, and indicate about 550-horse power. The boats are fitted with two rudders, one forward and one aft, which are actuated by steam, so that the manœuvring powers are exceptionally good. A great improvement has been made in these boats as regards the manner in which the torpedo tubes are enclosed within the framework of the hull, so as to avoid the evils attendant upon the arrangement previously adopted, in which case the forward end of the tubes were exposed without any protection whatever. The terms of the contract between the Austrian Government and Messrs. Yarrow & Co., were to obtain a speed on the measured mile of 20½ knots. On trial, however, 22·1 knots were made with the utmost possible ease, and it was clearly evident considerably more could have been obtained had Messrs. Yarrow so desired. A further official trial took place on the 31st ult. to test the consumption of fuel when running at a slow speed long distances. Messrs. Yarrow & Co., according to their contract, had undertaken that sufficient coal could be carried on board to ensure a run of 1,000 miles. It was found during a run of four hours' continuous steaming at a speed of 11 statute miles an hour, the exact consumption was 196 lb. of Welsh coal per hour. As, however, such a vessel can carry ten tons it is proved that torpedo boats of this size and description are capable of steaming a distance of over 1,200 miles without a fresh supply of fuel. It may, however, be mentioned that on some of the Greek boats built by the above named firm of the same size, fifteen tons of fuel were carried; therefore 1,200 miles may be considered as a very moderate estimate.

A NEW second-class torpedo boat, No. 70, which has been built and engined by Messrs. Thorneycroft, of Chiswick, having passed a satisfactory trial on the measured mile at Portsmouth, has been allotted to the *Inflexible*. With a pressure of 130 lb. of steam, the boat realized a speed of 16·7 knots per hour. This is considerably in excess of the contract speed, and a premium of £700 will be paid over to the builders in consequence. Hitherto, the great engineering difficulty which has been encountered in torpedo craft of this kind has been to prevent the priming of the boilers, and the leakage of the tubes at the boiler plates when pressed at full power. Indeed, while the water level was so close to the steam pipe as to cause the boiling water to find its way through the steam apertures, the priming exposed the plates in some instances to the intense heat of the furnace and caused them to buckle, whereby the heads of the tubes were dragged from their fastenings. In the new boat these defects have been remedied by removing the upper row of tubes, thus increasing the height of the steam space, the consequent loss of heating surface being made up by extending the barrels through the smoke box, and adding a foot to the length of the boiler. The tubes are now also made of brass instead of iron, and are fitted with steel ferrules. In the first-class boats the boilers are to be strengthened by screwing the tubes into the boiler plates, whereby the barrels will act as stays and prevent the buckling which now ensues from different rates of heat expansion. As the new torpedo boat was found to answer all expectations, the whole of those which have been sent to Portsmouth will be returned to the contractors to have the improvements introduced.

Carlton Tower.—The steamer, *Carlton Tower*, left the Tyne for Southampton, whence she will proceed on her charter from the Union Royal Mail Company to the Cape, with passengers and general goods, Owing to the confidence the owners have in the *Neptune* engines, the usual trial trip was dispensed with; and the builders, Messrs. Wigham, Richardson & Co., have been informed of her arrival at Southampton in 36 hours, which is an average speed of close on 11 knots, although being in very unfavourable trim, and having strong tides against her.

St. Jean.—This screw steamer, lately launched at Havre by Forges and Chantiers de la Méditeranée, and built to the order of Messrs. G. Le Roy & Co., proceeded to sea to make her trial trip on September 16th. The vessel's dimensions are 220 ft. by 29 ft. 6 in. by 16 ft. 9 in. Average speed of 11 knots was attained on the measured mile, instead of 9½ stipulated by contract, the engines indicating 460-horse power. A trial was made to ascertain the consumption of fuel, and the result showed a rate of 1·85 lbs. per indicated horse-power per hour. This result was very satisfactory, and the engines worked during the whole trip with perfect smoothness. The *St. Jean* left Havre and proceeded to Newcastle where she will take a cargo of coal.

Tower Hill.—This steamer, which is the second built or the twin screw steamship company of Liverpool, made her trial trip on the Firth of Clyde on Friday, September 16th. The *Tower Hill* is a steel vessel of 4,100 tons, is fitted with twin-screws, worked by independent sets of engines, and will carry 5,000 tons dead weight of cargo at a speed of about 13 knots. Her length is 420 ft.; breadth, 45 ft.; depth, 26½ ft. She has been constructed to suit both the eastern and western trade, being fitted with punkahs for the east and with heating apparatus for cold climates. The twin-screw, as has been shown in her sister ship, the *Notting Hill*, effects safety and economy. The consumption of fuel by the *Notting Hill* on her voyage to Calcutta is said to have been 1½ lb. per indicated horse-power, which is the most economical on record. The new vessel has ten of Turner's patent boilers, her crank shafts are made of Vickar's cast steel; she is fitted with steam steering gear by Harrison, of Manchester, and also with a powerful direct steam capstan windlass by Emerson, Walker, & Co., London. Besides having all the most modern improvements in shipbuilding the *Tower Hill* has passed the Admiralty Department for the transport of troops, having 11 watertight compartments, all of which extend to the deck and can be fitted as a cruiser in the event of war, the boilers and engines being protected by coal armour. On the 'tween decks she could carry 1,000 troops. As a trading vessel she can carry 1,000 head of cattle. There is accommodation for thirty cabin passengers, but that accommodation could be indefinitely extended. The *Tower Hill*, which is built on the same lines as her sister ship the *Notting Hill*, was built by Messrs. Dobie & Co., of Govan, who have also another vessel of the same description, the *Ludgate Hill*, on the stocks for the same Company. The engines, of which there are two sets, were supplied by Messrs. James Howden & Co., of Glasgow. They are inverted cylinder compound surface-condensing (tandem), the high pressure having a stroke of 32½ in. and the low pressure 48, and can be worked up to a steam pressure of 125 lb. The managing owners of the company are Mr. H. H. Nott, and Mr. W. Becket Hill, of Liverpool. The *Tower Hill* ran over the measured mile three times, and the mean speed obtained was about 14½ knots. It should be added that the propellers were not entirely under water. After the trial had been made the company sat down to luncheon which was purveyed by Mr. Forrester, Gordon-street, Glasgow, in the saloon. Mr. Young, of Dobie & Co., presided. In reply to the toast of "Success to the *Tower Hill*," Mr. Nott after referring to the advantages of the twin-screw, said the company had started at a rate of insurance lower than had yet been made in shipping. Mr. Hill also spoke of the advantages of such construction of vessels as in the *Tower Hill*, and pointed to the fact that the *Notting Hill* during her voyage to Calcutta, had behaved most admirably in all weather, and consumed 25 per cent. less fuel than the ordinary ocean-going steamers.

Erl King.—The steamship *Erl King*, belonging to Messrs. W. Ross & Co., of London, which has been fitted with a pair of compound high and low pressure direct-acting engines of 250 nominal horse-power, having cylinders 36 in. and 70 in. diameter respectively, with a stroke of 48 in., steam being supplied from two large double-ended boilers, carrying a working pressure of 85 lbs. per square inch, was, on Saturday, August 13th, satisfactorily tried under steam, everything working smoothly and without any heating. At 65 revolutions per minute the vessel made 12 knots per hour. The machinery, which is of the newest and most approved type, has been constructed, under the superintendence of Mr. John McDougal, consulting engineer for owners, by Messrs. David Rollo & Sons, Fulton Engine Works, Liverpool.

Correspondence.

[*It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.*—Ed.]

Dear Sir,—Will any of your readers kindly explain the process of ascertaining the pitch of a four bladed screw propeller, when it is lying on the ground, so that the boss is perpendicular to the ground; also,

Why is it, when a steamer is in a heavy sea way and the engines racing, that, immediately before the propeller leaves the water, the engines almost come to a stand-still, without the steam being shut off.

I enclose my card, and remain your obedient servant,

"A Young Third."

September 9th.

THE COLLAPSING OF MARINE BOILER FURNACES.

The following report by Mr. William Parker, the chief engineer surveyor to Lloyd's Committee, is of much interest and deserves careful attention.

Newcastle 100 *A Steamship Insurance Association.*

Newcastle-on-Tyne, August 16th, 1881.

Dear Sir,—At our recent settlement, in dealing with the appended report made to Lloyd's Committee by their chief engineer surveyor, my directors considered it so important and interesting to steamship owners, that I was instructed to send a copy of same to our members. I am, dear sir, yours truly,

Edward S. Scorfield, Secretary.

B. Waymouth, Esq., Secretary.

Lloyd's Register of British and Foreign Shipping,
2, White Lion-court, Cornhill, E.C.,
January 3rd, 1880.

Sir,—In accordance with your instructions I attended at Hartlepool, on the 29th December, for the purpose of investigating the cause of the apparently mysterious collapsing of the furnaces of the boiler of the screw steamer *Roumania*, which had arrived at that port a few days previously.

This vessel, which was launched only a few months ago, is the property of Mr. W. Gray, of West Hartlepool, and has been employed chiefly in the Mediterranean and Black Sea trades. She is fitted with a double-ended boiler made by Messrs. Thomas Richardson & Sons, of Hartlepool, who are also the builders of the engines. The boiler is 11 ft. 4 in. in diameter, and 14 ft. long, with four furnaces, two at each end, of 39 in. outside diameter, and 4 ft. 9 in. in length, the thickness being $\frac{7}{16}$ in. The furnaces are made in two plates having lap joints about 9 in. below the top of the fire-bars, and were made perfectly cylindrical. The two combustion chambers are common to both the forward and after furnaces without any division between them. The relative proportions of grate surface, heating surface, steam space, &c., are such as to render it an excellent steaming boiler, and no fault whatever could be found with its design, which is in accordance with the requirements of the Society's rules to work at a pressure of 85 lb. per square inch, for which pressure all the parts are amply strong. It appears that during the vessel's last voyage from Cardiff to Odessa, the whole of the furnaces collapsed in succession, the first one came down after about five days' steaming when the pressure was about 83 lb. per square inch, and was repaired at Lisbon, and the vessel proceeded on her voyage. On returning from Odessa this same furnace and another one gave out fourteen days' steaming under a pressure of 75 lb., while the two remaining furnaces collapsed about five days afterwards when the steam pressure was only about 50 lb. per square inch. The engineer stated that after each collapse the water in the boiler was changed, and the boiler run up with salt water. It is to be regretted that samples of the water that was in the boiler when the collapse occurred, and of that which was in use when the vessel arrived were not preserved, as an analysis of the same would have cleared up an important point in the case.

A careful examination of the furnaces showed that the damage to one furnace varied from another, only in the amount of depression of the indented parts, and the appearance of the plates being similar, it was evident that the collapse was caused neither by shortness of water nor accumulation of salt or scale. And any suggestion of structural weakness having caused the accident was entirely out of the question, as a furnace of the dimensions of those in this instance should be capable of standing in its cold state an ultimate collapsing pressure of about 550 lb. per square inch without showing any signs of weakness. So long, therefore, as the temperature of the plate did not far exceed the temperature of the water inside the boiler, the furnaces should have remained perfectly cylindrical under the approved working pressure of 85 lb. per square inch. But it was observed that the furnaces, tubes, shell plates, and all the inside of the boiler were covered with a black gluey coating of what appeared to be the refuse of the oil used in the lubrication of the cylinders. From the statement of the engineer, it appeared that at least half a gallon of Crane's mineral oil mixed with olive oil had been used each day for this purpose, and that neither the scum cock nor the blow-off had been opened while steaming. With the view of ascertaining how the deposit would affect water boiling when placed in direct contact with the surface of a plate, I suggested that an experiment should be made at the works of Thomas Richardson & Sons. Two dishes were made from boiler plate of the same thickness as the furnace plating of the boiler of the vessel; the inside of one was coated with a portion of the deposit, whilst the other was left clean; half a pint of fresh water was placed in each, and they were placed on the same fire, and the blast applied. The water in the clean dish commenced to boil in 25 seconds, but the water in the dish with the coating did not begin to boil until one minute and 25 seconds had elapsed, by which time the contents of the first dish had entirely evaporated. This experiment was repeated with the bottom of one dish covered with sand instead of the deposit, but no appreciable difference was observed between the sand-covered and the clean dish as regards time taken in boiling. A subsequent experiment showed that when the density of the water in the pan became greater, the deposit which had been placed on the bottom gradually mixed with the water, and eventually rose to the surface. The results of these simple experiments would seem to indicate that the deposit found in this boiler is a great non-conductor of heat when placed in direct contact with the surface of iron plates, and might be sufficient to account for the plates becoming heated and softened to such an extent as to be unable to resist the external pressure, and so collapse ensue, either shortly after steam has been raised or when the vessel has been steaming for some days. In the latter case, it would appear that in a boiler having large quantities of the refuse, this latter, which when steam was lowered would fall to the bottom of the boiler, remains there undisturbed, until by frequent extra supplies from the sea, the density of the water in the boiler is increased, when the sediment gradually ascends and mixes with the water, imparting to it, especially in the narrow water spaces between the furnaces, a consistency so great as to be incapable of absorbing the heat, the ultimate collapse being then only a question of time.

In order to avoid such accidents in future I would recommend that:—

(*a*) More care be taken in cleaning the boiler.
(*b*) Much less oil than half a gallon daily be used for lubricating the cylinders of an engine of this power, and
(*c*) Nothing but pure mineral oil be used.

I would also suggest the desirability of occasionally scumming, which has for some time been greatly abandoned in high-pressure boilers.

I may further add that this is not the first case that has come under my notice of furnaces collapsing in a somewhat mysterious manner.

The particulars of each case as far as obtainable are being carefully noted as they occur, and it is to be hoped that we may eventually be enabled to arrive at a conclusion which will satisfactorily account for the varying circumstances under which collapses have occurred.

The principal difficulty is to secure perfectly accurate and reliable information of the surroundings of each case.

I am, Sir, your obedient servant,
WILLIAM PARKER,
Chief Engineer Surveyor.

ANTI-FOULING AND ANTI-CORROSIVE COMPOSITION.

To the Editor of THE MARINE ENGINEER.

SIR,—Our attention has been called to an article in your impression of the 1st September last, on the subject of Anti-corrosive and Anti-fouling Compositions for ships' bottoms.

For the information of your readers and those interested in this all-important subject, we would ask you to favour us by inserting in your next number the following particulars of Gay's Marine Paints.

These paints were brought into use many years ago; but due to the decease of the inventor they have been allowed to lie dormant, until we took up the sale of them; which was only done after thoroughly satisfying ourselves of the great merits of the compositions.

We are able to state with confidence that of the numerous steam and sailing ships, which have been coated with these paints, notwithstanding many of them have been lying in badly fouling water for months at the time, no single failure has been brought under our notice.

The business is now being extensively worked by us, and we trust, ere long, to see these paints take that prominent position amongst competitors, which their great value warrants them in doing.

We should add that the Anti-corrosive paint is of such a nature that the first coat at once allays anything like rust of the iron, and at the same time forms a solid foundation for the other coatings.

The Anti-fouling Composition is so compounded that with the action of the sea water an exfoliating surface is produced and maintained, to which nothing in the shape of animal or vegetable matter can possibly adhere, but falls off at the moment of contact.

The great test of the merits of an anti-fouling composition is when applied to the bottoms of *sailing vessels*, which are at times obliged to remain for a long period inactive in a fouling harbour; such tests we can point to with the greatest satisfaction, as resulting from the use of Gay's Marine Paints.

In verification of the value of these paints, we add the Testimonial of the commander of a ship, the bottom of which was coated with them. She made several voyages out and home and was not redocked for TWO YEARS, after that time she was docked for examination and found to be perfectly clean and the plates well preserved.

This gentleman writes,—"I should always use your paints, as I never found or saw any others that excelled them as Anti-corrosive or equalled them as Anti-fouling Compositions."

Yours truly,
BROWN STEVENSON & CO.

To the Editor of the MARINE ENGINEER.

SIR,—I have read with interest the remarks upon Anti-Corrosive and Anti-Fouling Compositions in your September number. For the last twenty years I have served in iron ships, and during that time I have had experience of a number of Patent Compositions. I entirely agree with you in saying that a really effective composition is one of the great scientific requirements of the day; but there is one fact bearing upon the question to which I do not consider sufficient importance is attached, and that is, the manner in which compositions are applied to ships in dry dock. It is a fact well known to commanders and officers of steamers, that the time devoted to dry-docking and painting a vessel is very much grudged by the managers of large steamship companies, and the operation is generally a very hurried, and consequently a very imperfect one. It is no uncommon occurrence for a mail steamer to go into dry dock to be scrubbed, and very imperfectly scraped as the water leaves her, and for the painters' gang to follow immediately after the scrapers, thus giving the iron no chance to dry, and preventing the composition subsequently applied, from having a fair chance. Of course there are exceptions to this, but I have experienced it to be the rule.

Again, in a matter of so much importance, too great economy is not always the best policy, the number of coats applied should be regulated by the length of time that the ship is destined to be away, and the nature of the seas she is to ply in; but these are considerations frequently left out of sight by shipowners, and when the vessel returns loud complaints are made against the composition used, whereas a little more liberality in its use would probably have obviated the cause of complaint.

Another great mistake, frequently made, is chipping an iron ship with chipping hammers. This is a practice (in my opinion) to be avoided, it breaks the skin of the iron, and causes it to present a rough surface, favourable to the adhesion of animal and vegetable substances. An iron ship once chipped never recovers its pristine smoothness. Even in using the scraper great care should be used, and the officers of steamers and iron sailing-ships should be instructed to keep a bright look out upon the men employed on the stages, and forbid any hammering or rough scraping at all.

With reference to the composition used, the first consideration is to get a priming which while anti-corrosive, should contain no ingredients inherently antagonistic to iron, and this should be allowed fairly to dry before application of a second coat; this precaution, however, is frequently neglected, the great object being to get the ship on to her loading berth as fast as possible. I do not think I overrate the importance of this subject, when I say that the duties of steam-ship officers are important in dry dock, and require as much vigilance and attention as their duties on the bridge at sea, and conscientious officers will by no means neglect them.

The name of Anti-fouling Compositions is legion, and the difference of opinion as to their respective merits is great. I have found tallow and sulphur mixed and applied hot very effective for a short time, but it soon scales and comes off in large patches leaving the bare iron, and for a long voyage is useless. I believe that the compositions containing copper in any form are absolutely injurious to the iron. Although useful as anti-foulers, probably the best composition yet brought out is the Ferro Mangnesie Composition known as Foulger's Composition; this I believe to be the coating of the future, but whatever composition is used none will be effective unless the care I have referred to be used by those whose duty it is to superintend the cleaning and painting of iron ships.

It is unfair to the manufacturers of anti-fouling compositions to throw the entire blame of their non-efficiency upon the compositions themselves, where the instructions for applying them have been altogether neglected. Only the other day in the course of a conversation I had with one of Lloyd's surveyors the following circumstance was related to me. A large Liverpool steamer had just come into dock off a long voyage with her bottom as foul as a half-tide rock, she was coated with a well known composition, but it transpired that the anti-fouling composition had been used as a priming, and the priming put on over it; the fault was clearly the painters in the first place, and of the officers in charge in the second, always presuming that the casks were properly marked.

As a matter of fact we are only now beginning to learn the merits or rather the demerits of compositions. Iron shipbuilding is only in its youth, and sufficient time has not elapsed to enable a correct opinion to be formed of the effects of various ingredients upon the iron itself; the only safe plan is to adopt those compositions which are formed of ingredients which have an ascertained affinity for iron, and avoid those which have a deteriorating effect. There should be no reason why the life of an iron ship should not be with proper care, fully equal to, if not greater than the period assigned by the Psalmist to man.

Apologizing for troubling you at this length, and enclosing my card.—I beg to subscribe myself,

Yours truly,
A MAIL BOAT OFFICER.

To the Editor of THE MARINE ENGINEER.

SIR,—I was glad to read in your last number that your columns were open for the ventilations of the subject of Anti-corrosive and Anti-fouling Compositions for iron ships.

It has been my duty for the past ten or twelve years to investigate into the merits and demerits of the numerous compositions for preventing corrosion and fouling, as they have been brought out from time to time, and to report thereon. I shall be glad if you will give publicity to the result of my experience for the benefit of those who may be interested in this important subject.

In many instances the cause of failure of a composition has been due to the ship and dock owners rather than to the manufacturer. Ships are docked, the bottoms are washed down and scraped as the water leaves them, and the priming coat is immediately applied before the surface of the iron has had a chance to dry: the result being that the moisture on the surface of the iron is hermetically sealed with a waterproof coating formed by the application of the first or priming coat. Rust is consequently produced, and after a time scale is formed which drops off leaving the iron quite bare; corrosion now goes on at a rapid rate, and by the time the ship is redocked her bottom looks like a honey-comb.

Another cause of failure has been where the composition used contained copper in some form, and galvanic action has been set up, and after a time the iron became honey-combed, and corrosion went on increasing, eating its way into the iron, so that in a comparatively short period the plates became so deteriorated that they had to be replaced with new ones.

In other cases the composition used has decomposed in a short time by the action of the sea water, and the iron has been left bare. A composition made of zinc and tallow is now extensively used on sailing ships, but it soon decomposes and is only suitable for short voyages, and consequently it is highly recommended by dry dock owners.

My experience has taught me that no greater difficulty need be encountered in the preservation of iron ships from rust or fouling, than there was in the days of wooden ships, always provided due care is taken by the owners to allow sufficient time in dock for the work to be done well and to dry properly.

The surface of the iron, when in a foul state, should be scrubbed and scraped and allowed to dry; a priming coating of a good anti-corrosive paint or composition should then be applied, and this composition should be so compounded that it does not flake off, nor is in itself injurious to the iron, it should enter well into the pores of the iron to allay the progress of rust already formed.

Still another coat of such a composition should be applied on the top of this when dry, and finally the anti-fouling coating should be applied.

Upon the nature of this anti-fouling composition, really depends the success or non-success of the operation.

I have been at times obliged to listen to the most foolish remarks by the manufacturers of various compositions. Such as, for instance, "The compositions we make dry as hard and smooth as glass, nothing can stick to them." The fact is, that limpets and barnacles select hard and smooth surfaces to stick to, and vegetable matter also.

A good anti-fouling coating should be so compounded that it exfoliates from the surface immediately adhesion of any substance is attempted, but does not come off by the action of the vessel passing through the water. It should also be durable and without any ingredient that is injurious to the iron.

Some years ago I tested a composition which was in one instance applied to the bottom of a sailing ship, the *Winifred*, and she was properly done; she was abroad for TWO YEARS, lying for months together in badly fouling harbours. Nevertheless, on her return, upon examination of her bottom, she was found to be entirely free from fouling or rust.

The anti-fouling composition used in this instance was of an exfoliating nature, such as described above, and I am convinced that no surface, whether it be poisonous or otherwise, unless exfoliating, will prevent the adhesion of barnacles and weed.

If shipowners looked more after their own interests, and left less in the power of dock proprietors and their officials, there should be no difficulty in preserving the bottoms of their iron ships. A good and durable composition does not suit their purpose like one that would require to be re-done every voyage, and consequently a zinc and tallow composition is their friend, and they strongly recommend it.

Yours faithfully,
Ex Naval Officer.

To the Editor of the Marine Engineer.

Dear Sir,—We have read with pleasure your article on Anti-corrosive and Anti-fouling Compositions for ships' bottoms, in the current number of the Marine Engineer.

For some time past we have been engaged in bringing to the notice of shipowners our anti-fouling composition for ships generally, wood and iron, but finding great prejudice existing amongst ship-owners, and an unwillingness to grant those opportunities of a trial, which we sought, we determined to submit the composition to the Admiralty.

In due course we received a letter from the Secretary of the Admiralty inviting us to make trials on an iron vessel lying in Portsmouth Harbour. These trials were continued over a period of three years, at the end of which, the composition having stood the test, we received an order to coat the vessel entirely and for which we were paid.

The last trial was made in October, 1878, and on the vessel being docked for examination of bottom in April, 1880; (eighteen months after), the iron was found to be thoroughly preserved, the bottom free from vegetation, and the composition intact.

We will not dilate upon the merits of this composition, the trial speaks for itself.

We are, dear sir,
Yours truly,
Noldwritt & Murray.

6, Water-lane, Tower-street,
London.
September 20th, 1881.

LOSS OF LIFE AT SEA.

To the Editor of the Marine Engineer.

Sir,—The calamities that so frequently occur from shipwreck and other disasters at sea, involving such fearful sacrifices of human life as that from the wreck of the s.s. *Teuton* at the Cape, and the s.s. *Tararna* at New Zealand, and many other instances of a similar character, should cause the subject of "Loss of Life at Sea," and the means of averting such calamities, to be seriously considered by those who undertake the carrying of living freights from one part of the world to another, as also by the Government and its officials.

For ages past there has been a continuous sacrifice of human life from disasters at sea which might have been prevented by the adoption of means of a most simple and effective kind.

Vast sums of money, much skill and ingenuity are devoted to the means of destroying life, but very little consideration is given to the means of saving life, especially from disasters at sea.

In consequence of the fearful loss of life from the wreck of the s.s. *Atlantic* and the running down of the *Northfleet*, when nearly a thousand lives were sacrificed about eight years since, I was induced, while in Australia to give my attention as to whether some effective means could not be adopted to prevent such calamities in the future, which resulted in my invention and introduction of several articles for general use on ships which can be readily used for that purpose.

I was fully satisfied that it would not be advisable to design a lot of useless cumbersome articles to be carried about a ship for the purpose of meeting a contingency that may not happen, while it was possible to make the several articles of ship furniture such as mattresses, couches, seats, pillows, &c., of such a bouyant and convenient character as would not only answer the ordinary purposes required of them, but in time of danger are available for immediate and effective use as a means of saving life. I therefore determined, and have demonstrated conclusively, that the beds must be made the chief article of use for that purpose, and if vessels be fitted up according to the plan I propose there need be very little, if any, loss of life under ordinary cases of shipwreck. It is the simplest, most economical and only effective means that can be adopted to save the lives of passengers in time of sudden disaster.

As every man, woman, or child going to sea have to be provided with a bed, in the name of common sense and the instincts of humanity, why should they not be provided with a bed that would be of some service in time of danger, instead of the useless articles now generally used.

It was not only necessary that the beds, couches, seats, &c., should be made of such thoroughly buoyant material as will safely float its occupant in water, but it was also necessary that they should be so constructed as to be readily tied together for the formation of rafts or lashing outside of boats; and for that purpose have I specially designed them, so that it matters not whether there be ten, or fifty, or five hundred persons on board ship, if each is provided with a life preserving mattress, as I suggest, then there is not only enough bouyant material ready at hand to float all hands with safety, but the shipowners will be free of blame or moral responsibility for not having made provision to meet such cases of maritime disasters as so often occur, and with such fearful results.

I unhesitatingly assert that there is no necessity for this continuous sacrifice of human life by drowning from shipwreck, and the wholesale destruction of humanity that has been going on unchecked for years is a disgrace to our intelligence and civilization.

The best vessels afloat and the most skilful officers are liable to accidents, and it is when the largest vessels are wrecked that the great loss of life takes place. It is, therefore, incumbent on the owners of vessels to provide such appliances as practical experience has proved to be most effective.

When a public disaster, like that of the *Princess Alice* or the *Teuton* takes place there is usually displayed a large amount of practical sympathy to relieve the widows and orphans of the unfortunate sufferers, but how much better would it be if a little more practical philanthrophy was displayed to prevent such disasters from occurring, by having the vessels properly fitted with life-saving appliances.

I am in a somewhat invidious position in reference to advocating the cause of saving life from shipwreck, simply because it would appear to be advocating my own personal advantage; but I am, however, at a loss to conceive why the subject should be refused discussion in the public press on that account, and trust that your sense of justice to the cause of humanity, and the special advantages of safety that would accrue to seamen and passengers by having this question discussed and acted on, will ensure this letter a place in your valuable paper.

The question resolves itself into one of common sense, intelligence, and humanity, as against prejudice, ignorance, and foolhardiness. Nature has abundantly supplied mankind with material possessing such bouyant and healthy properties, that if utilized for bedding and other ship furniture, can be made the means of materially reducing the loss of life and averting the dangers of the sea, without materially enhancing the cost of fitting up of ships. It is surprising that so many should ignore the teachings of natural laws and the principles of humanity and self-preservation, by refusing to adopt such articles for saving life as practical experience have proved to be most effective.

I am, Sir, yours, &c.,
Thomas Cornish.
Inventor of Life Saving appliances.

109, Fenchurch Street,
London E.C.

The City of Dublin Steam Packet Company's vessels are being fitted up with the necessary apparatus for lighting on the Pintsch system.

Gravesend is, after the 4th inst., to be the port of embarkation for the Peninsular and Oriental Company's steamships, instead of Southampton. The new steamer *Rome* leaves on that day. Arrangements have been made with the London, Tilbury, and Southend Railway for the despatch of a special train from the Liverpool Street station of the Great Eastern Railway, at 11 a.m. every Tuesday, to Tilbury, whence passengers will be conveyed to the company's vessels in a commodious river steamer.

⁂ Any information regarding these or other patents will be gladly furnished on application.

The most flourishing branches connected with iron and steel are, according to Messrs. Bolling & Lowe's *Iron Trade Report* the shipbuilders and heavy engineering trades connected therewith. According to the most recent register at Lloyd's, it appears that the number of steamers built in 1879 was, iron, 270 tonnage, 463,414 tons; steel, 23, tonnage, 21,222 tons; total, 484,666 tons. In 1880, iron ships, 401, tonnage, 487,404 tons; steel ships, 30, tonnage, 38,164 tons; total, 525.568 tons. In progress of building 1st July, 1881, there were of iron, 550 ships of 900,000 tons; and of steel, 50 ships of 120,000 tons; giving a total of 1,020,000 tons an enormous increase upon last year's operations, nearly doubling the figures in about six months. The nnmber of steel boilers built was 1878-79, 220; 1879-80, 380; 1880 81, 500; and at the present moment there are 528 pairs of marine engines and boilers building of effective horse-power 500,000.

BOARD OF TRADE EXAMINATIONS.

Return of Engineers reported to have passed examination under the provisions of the Merchant Shipping Act, 1854, during the month.

EDITORIAL NOTES.

THERE has been much dissension amongst naval architects and other experts as to the question of how far steel ships pay for their extra cost of construction over iron ships. We have ourselves defined that this point will depend largely upon the average class of freights which they are in the habit of carrying. As a valuable datum to this controversy, we are glad to be able to refer to the results from a dead-weight carrying steamer engaged in the Bilbas ore trade. It was built of steel in 1877, at a cost of £18,350, that is an increase of £1,350 above what her cost would have been if she had been built of iron. By the lightness of the hull, obtained by the reduced scantlings of the steel, she has been enabled to earn £840 gross per annum in addition to what she could have earned from her carrying capacity had she been of iron. If from these gross extra earnings are deducted the cost of discharging the extra cargo and the extra insurance, &c., there is still left a yearly gain of £560 for the additional outlay of £1,350. This is not a bad return, amounting as it does to over 40 per cent. Our former remarks must, however, be borne in mind that this result, which may apply to every dead-weight carrying cargo vessel, will not apply to bulk cargo carrying vessels, such as cotton or grain, nor even to general cargo vessels, as the additional lightness of the hull gained by the use of steel would not in such cases add anything to its freight-carrying capacity.

THE Government have just discovered a mine of unrealised wealth. Engine work, as we all know, is mighty expensive, and as an engine cannot vanish into thin air, and, if well treated, is very little the worse for wear as year by year goes on, the engines of steamers thrown out of commission ought to be as serviceable as ever, barring any old fashion that there may be about them. As, however, cylinders are always cylinders, and pistons, cranks, and air-pumps have not varied much in construction during the lifetime of the last generation of ships, the engines therefrom should have at least a certain value and usefulness for further application. It has, however, never been the habit of the English Government to realize the value of such engines when the steamers have been paid off. This has been a great error, as the deterioration of engines or boilers is much greater when lying still out of use, than when in constant work. We may enumerate amongst ships which are entirely laid off, the *Victoria*, the *Howe*, the *Royal Albert*, the *Defiance*, the *Anson*, the *St. George*, the *Royal William*, the *Albion*, and the *Rodney*. The original cost of putting engines into these vessels amounted to £368,000. There are also engines worth originally as much more in steamers pronounced "incurable," in the sense of being unfitted for taking a place in our present iron-clad Navy. Surely these engines, amounting in their gross original value of over £700,000, are worth realizing, and if all such hulks, with all fittings, were promptly realized as they become out of date, the proceeds would go far to help the Naval Exchequer for the expensive experiments which are now so necessary.

THE voyage of the *Inflexible* is being watched with considerable interest. Some little disappointment has been felt that her speed on the measured mile was not better. In her run from Portland to Plymouth she has, however, done better, inasmuch, as she has made 12 knots the entire way, and only with 50 lbs. of steam instead of 60 lbs. in her boilers. As is frequently the case with new machinery, it warms to its work after some little time has elapsed. In the matter of steering also the vessel has much improved from greater experience in handling her. It is, however, the general opinion that her rudder is scarcely large enough, which probably will be remedied at Malta. The weather on leaving Portland was rather heavy, and the behaviour of the vessel was considered very satisfactory. The lower booms were forced adrift but were got on board and secured on the top of the poop. A further novelty under trial in the *Inflexible* is the water balance chamber. This chamber carries 70 tons of water, which is applied for the purpose of checking the roll of the vessel. This was suggested by the late Mr. Froude and promises to be very effective for the purpose.

WE have before us a circular from a north country sea-going Engineers' Association which is deserving of every attention and support. The value to individual members of any trade or profession by banding themselves together is now well recognized, not only does it give an efficient means for resisting an undue pressure for the reduction of wages, but as a means for insurance against death, injury, or legal proceedings, its value may be sensibly felt in the ordinary routine of work. The association in question, dating its head-quarters from Sunderland, already numbers 700 members, and eight branches of it very sensibly seeks to affiliate all sea-going engineers or other already formed Societies in connection to itself. This Association is in direct communication with an Australian Society of sea-going Engineers, numbering over 400 members. By means of these intercommunications the rate of wages in Australia is always known to the English Association, and the engineers making contracts in England for service at the colonies can be advised, if a member of the Association, what is the regular rate of wages obtainable on the station. Loss of clothes by shipwreck is also made up to the members of the Association by a payment of £5. This amount, though small in itself, is very welcome after such a loss, and a special payment is made to the widow in the case of the death of a member.

THERE is still hope of rendering a great deal of the comparatively light artillery serviceable against modern armour-plated vessels. The 9 in. gun has hitherto been regarded as obsolete and useless against armour, as the energy of the projectile, 3,500 foot-tons, is a mere trifle compared with the 27,300 foot-tons developed by the 16 in. or 80-ton gun. It has however, been discovered that the penetrating power of a projectile depends as much on the material and the shape of the penetrating face, as on its energy of motion. A shell of a special quality of wrought iron has been manufactured at Woolwich, which combines in a wonderful degree the qualities of hardness and toughness. A greater length of projectile with a much more angle of point than has hitherto been used, have been now experimented on, with most striking and startling results. The target representing an armoured vessel was penetrated, backing and all, and the results may be considered as doubling the effective power of modern artillery.

EXTENSIVE MASONRY WORKS AT THE DUBLIN CUSTOM HOUSE DOCKS.

(FROM A DUBLIN CORRESPONDENT.)

A PARTY of members of the Social Science Congress here have visited the Custom House docks and vaults. They proceeded to the north wall extension for the purpose of seeing a great block of concrete, 350 tons, forming part of the series of which a boundary wall of the extension is composed, put into its place. These works were commenced ten years ago. Over a thousand feet of the extension is complete, forming a roadway of 250 ft. wide. On the south side of this is the river. On the north side a tidal basin, already in use for shipping, which will be 2,500 ft. long when finished. The boundary walls of the quay on each side are formed of blocks of the size now deposited. The first of them was set on the 27th of May, 1871. The one now placed was the 326th block. Each is thirty-one feet high, and of proportionate dimensions otherwise. They have been all made at one side of the basin, the component parts being irregular masses of Dalkey granite, Portland cement, and gravel dredged from the river. The ,cement and gravel are mixed by steam machinery. The materials are put into a mould, framed of boards, where they remain until consolidated. These blocks are lifted from one side of the basin to the other by a large iron vessel, 1,600 tons burden, called a "Shears" float, which is furnished with steam engines, enormous iron arms in derricks, extending to a great height at one end, and iron chains and pulleys of massive size and peculiar construction. The hull and arms of the vessel were made in the yard of Harland & Wolff, Belfast. The steam engines are by Grendon, of Drogheda, and the deck machinery of cog wheels, to which the chains are attached and by which the requisite power is gained, is by Messrs. Courtney & Stephens. In the first part of the operation—the lifting of the block from where it was made—the pulleys from the arms of the shears are attached to four iron bars passing through the block, and the ends of which project through the upper part of it. The process of lifting is always begun when the tide is rising, and it takes place when the barge is "hove short" —to use a nautical expression—upon the block, like a ship upon her anchor, through the combined power of the rising tide and the machinery. In case of necessity, however, the machinery alone would do the work. The depression at the end of the vessel from which the shears extend, caused by the weight of the block, is balanced by pumping water into a compartment at the other end, so that she can be brought to an even keel. The shear's float, with this ponderous block suspended from her arms, was warped across the basin to a position next the wall which is being built, where she lay when the visitors arrived. It was then low water, and the moment the men got on board, the "breaks" on the machinery were relaxed, and the block slowly descended into the water, which was then about twenty-eight feet deep. The site at the bottom had been previously prepared by men who worked from a diving-bell. By movements of the vessel and her chains, and by wedges, the block was adjusted in its place with precision.

HER MAJESTY'S SHIP "INFLEXIBLE."

THE double turret ship *Inflexible*, Captain J. Fisher, steamed from her moorings on the morning of October 17th, shortly after 7 o'clock, for the trial of her engines on the measured mile in Stokes Bay; and as this was the first occasion of her leaving Portsmouth harbour since she was commissioned, she saluted the flag of Admiral Ryder, the Commander-in-Chief, on arriving at Spithead. The trial was conducted by Mr. Charles Iceley, on behalf of the Steam Reserve, and was watched by Mr. E. Newman, on behalf of the Dockyard Steam Department, while the practical management of the machinery was superintended by Mr. J. H. Heffernan, the chief engineer. The importance and novelty of the trial attracted a large number of interested witnesses of the behaviour of the engines and ship, among whom may be mentioned Captain Colomb captain of the Portsmouth Steam Reserve; Mr. James Wright, C.B., Engineer-in-Chief; and Mr. W. H. White, Chief Constructor at the Admiralty; Professor Sir William Thomson; Mr. R. Barnaby, Constructor at Portsmouth; Admiral Raby, V.C.; and Captains Hallowes and Beaumont. Admiral Ryder witnessed the steaming from his yacht, and at the conclusion of the trial he went on board and inspected the ship.

The propelling engines, were manufactured by Messrs. Elder & Co., of Glasgow, each of the twin screws is worked by independent compound engines of the inverted or hammer type, having each a high-pressure and two low-pressure cylinders. The high-pressure cylinders are 70 in. and the low-pressure cylinders 90 in. in diameter, the stroke being 4 ft. The steam from the low-pressure cylinders is exhausted into separate condensers, having a total cooling surface of 16,000 square feet; and in being condensed, it passes through an aggregation of tubes of ¾ in. external diameter, of which each condenser has no fewer than 6,650. The expansion is effected by link motions on the main slides. At starting, the engines are assisted by auxiliary steam gear, the valves of which are fitted to the receiver. Steam is furnished by 12 boilers, eight single ended and four double-ended, the latter being placed along each side of the middle line bulk-head.

Since the ship was commissioned, much has been done by Captain Fisher to improve not only her efficiency as a fighting engine, but her appearance; and as she proceeded to Spithead a great deal might be said, notwithstanding the general impression as to turret ships, in her favour from a purely pictorial point of view. The turrets and superstructures, which are painted black, are surmounted by a somewhat rakish white riband, while a yellow weather cloth, which runs in a line along the weather deck and the tops of the turrets, conceals the open spaces under the bridge, and gives the monster the appearance of a broadside ship. The weather was particularly fortunate for the steam trial. The sea was perfectly calm, a light breeze blowing with a force of four from the south-east, and consequently upon the starboad bow and port quarter, while the ship was making her runs upon the mile. Owing to there being considerable difficulty in getting up a satisfactory pressure of steam in the boilers, the preliminary cantering in the Solent for the purpose of coaxing the fires lasted until 10 o'clock, when the first run was made on the mile. It will, however, be seen that, although the blast was kept on throughout the trial, the average pressure of steam was not equal to the actual load of 60lb. on the safety-valves. There was, therefore, no waste, the engines utilizing all that could be passed through the cylinders, notwithstanding the fact that the propellers, which, on the light trim six hours' trial, had a mean pitch of 20 ft. 6 in., had had the pitch coarsened to 21 ft. 6 in. The following are the results of the four full-power runs:—

	Revolutions.		Speed.
	Starboard.	Port.	Knots.
First mile ...	71·96	70·30	12·371
Second mile	71·65	71·00	12·950
Third mile	72·55	71·49	12·766
Fourth mile	72·46	71·40	12·676
True mean speed			12·774

It was originally intended that two runs should be made upon the mile at two-thirds power, and two runs at one-third power. In consequence, however, of the delay which took place at the beginning of the day's work, the tide proved unsuitable. Dangerous shallows began to show themselves, and it was only by the pilot, Mr. Harding, making a *détour* to Cowes and rounding the middle buoy, that the last two full-power runs could be completed. The following are the mean results of the steaming:—

	Starboard Engine.	Port Engine.
Steam in Boilers, 58·25lb.		
Vacuum, Forward	27·12	27·31 inches.
„ Aft	27·37	26·37 „
Revolutions per minute	72·15	71·04
Mean Pressures, High ...	29·1	29·87lb.
„ Low	9·56	8·97lb.
Indicated Horse-power, High...	1,959	1,980
„ „ Low ...	2,128	1,967
Total Indicated Horse-power ...	4,087	3,947
Collective Horse-power	8034	
Speed of Vessel...	12·774 knots.	

So far as the performances of the engines were concerned these results where highly satisfactory. There was no priming, the vacuum was good, and there were no hot bearings. The collective horse power developed by the engines was also 30 horses beyond the contract, and 136·68 more than were obtained at the six-miles run with the same propellers, though 373 horses fewer than were obtained during a similar protracted run with the two-bladed propellers. In comparison, however, with the trial in December last the mean speed realized was somewhat of a disappointment to many on board. Had the trial fulfilled the ordinary stringent conditions of a measured mile trial, the difference in speed between 12·774 and 14.286 knots per hour would have been inexplicable. The trial however, was less for comparison of results than for the satisfaction of Captain Fisher before proceeding on his experimental cruise, and for the information of the Constructive Department of the Admiralty, though with regard to the latter purpose it is probable that, owing to an eccentricity in the steering, the *data* will be considered of small value. Although the *Inflexible* did not receive her powder and shot until after the trial, and had only 850 tons of coal on board, or about 300 tons short of her normal quantity, her draught was 24 ft. 2 in. forward, and 26 ft. 2in. aft, giving a mean draught of 25 ft. 2 in. This produced an immersion of the upper edges of her screws of 4 ft. 11 in., and brought the hull bodily down in the water some 2 ft. beyond her light draught, representing an increase of about 2,000 tons in the ship's displacement. Under this additional strain upon them the engines could not get away. Then the ship had been five months out of dock, so that, judging by what invariably takes place in similar circumstances, the bottom must have been foul with grass and other growths. But the most important drawback as regards speed remains to be stated. While making the first run on the mile from west to east it was found that in order to keep the ship in a straight line it was necessary to give her 18 degrees of helm. A similar phenomenon was observed during the steam trials of the *Northampton*, but in this case the required helm was permanent, and might have been necessitated by some defect of symmetry in the lines of the hull itself. In the *Inflexible*, however, the eccentricity in the steering was found to be variable, for on the first and third runs, which were made in like directions and under apparently similar conditions, the 18 degrees of helm were in one instance starboard helm, and in the other port helm. It will be seen that the revolutions of the engines did not exactly synchronize, but the difference of a revolution a minute would have no perceptible effect. The cause of the defect appeared to perplex everybody on board, some attributing it to the wind and others to the current; but, whatever the cause, it was estimated that the divergence of 18 degrees from amidships must have produced the loss of a knot in the way of the ship.

THE NEW S.S. "ROME" AND "CLYDE."

TWO splendid steamships, the *Rome* and the *Clyde*, which have just been added to the fleet of vessels, upwards of sixty in number, belonging to the Peninsular and Oriental Steam Navigation Company, were inspected lately by the directors. The steamers were berthed in the new and spacious Royal Albert Dock, which is at present the easternmost, and consequently nearest to the Channel, of the series of great docks on the north bank of the Thames. With the sailing of one of the new ships, the *Rome*, for Australia, the change of the port of embarkation for outward-bound passengers commenced, and from that day the company's steamers cease to go to Southampton, and passengers will be put on board at Gravesend. Arrangements have already been made with the London, Tilbury, and Southend Railway Company for the despatch of a special train from the Liverpool-street Station of the Great Eastern Railway for the conveyance of passengers to each steamer on the day of sailing. From the Tilbury riverside terminus of the railway passengers will be taken to the company's vessels in a river steamer. On the homeward voyage the company's steamers will call at Plymouth so as to give passengers an opportunity of saving a few hours by taking train to London. A feature in the internal arrangements of the *Rome* which will commend itself at once to most travellers is the placing of the best state-rooms, the saloon, and the music-room forward instead of aft of the engine-room. An arrangement which had its advantages in a sailing vessel, since the wind as the propelling force must, either through the stern ports or through the port-holes on one side or the other, reach the saloon fresh and untainted by the often malodorous air from between decks in the forward part of the ship, is so evidently unsuitable to the conditions under which steamers frequently make their way against a head wind or during a calm, that it is rather matter for surprise that passenger-carrying steamship companies have not generally adopted the plan of putting their best customers where they are least likely to be annoyed by the smell of cargo and engine oil. The *Rome* has accommodation for 160 first-class passengers, and it may be added that the fitting-up of the parts of the ship devoted to them appears to be all that could be reasonably wished for. The great dining saloon on the main deck, 50 ft. long, and the full width of the ship 44 ft. across, is well lighted and ventilated. The decoration of the walls with large square panels of Italian walnut, elaborately carved by Signor C. Cambi, of Siena, is something novel in a steamship. Instead of fixed bench seats, there are chairs which turn on pivots, so that passengers can take their seats or leave them, which is perhaps to most of more importance in the early days of the voyage, without disturbing others at the table. Over the dining saloon is the music room, an apartment 40 ft. long, very handsomely decorated and furnished, and, also on the upper deck, a comfortable smoking room. The state rooms are on the main deck, and near them are the bath rooms, with marble baths, and a constant supply of hot and cold water. Immediately aft of the engine rooms are saloons and cabins affording accommodation for fifty second-class passengers, for whose comfort, indeed, the provision made in the *Rome* is more complete than in the first-class quarters of the older vessels on many steamship lines. The great width of the upper deck leaves room on each side of the deck houses for a broad promenade, which will be reserved for the use of first-class passengers. The vessel has many watertight compartments, and nine separate pumps in the engine room, and there are nine boats, of which four are lifeboats and one a steam launch. Special provision, too, is made for extinguishing a fire. The principal dimensions of the *Rome* are—Length, 430 ft.; breadth, 44 ft.; depth, 36 ft.; gross tonnage, 5,100 tons; with cargo-carrying capacity of 4,000 tons. She is practically a four-decker, for there is a hurricane deck. This is 300 ft. long, and is connected with the full poop and forecastle by portable bridges. On the forecastle is a steam windlass for raising the anchor, and on the poop a steam warping engine, in addition to steam winches, four powerful steam cranes, and other appliances for rapidly taking in or discharging cargo. Messrs. Muir & Caldwell's steam gear is employed for steering. A refrigerating machine on the Bell-Coleman principle is carried. The ship is engined with two pairs of compound tandem engines of 1,000 horse-power nominal and over 5,000 horse-power indicated. There are two low pressure cylinders, each measuring 82 in. diameter, and two high pressure cylinders of 44 in. diameter. The steam pressure is 90 lb. to the square inch. Each piston rod weighs four tons, is 13 in. in diameter, and has a five-foot stroke. The massive crank shaft, of Vicher's steel, weighs 30 tons. Steam is generated in four double-ended and two single-ended boilers heated by thirty furnaces. She is fitted with four masts and two funnels. The builders and makers of the engines were Messrs. Caird & Co., of Greenock. The other new ship, the *Clyde*, which has been built and engined by Messrs. Denny Brothers, of Dumbarton, is in general arrangement similar to the *Rome*. She is, however, rather smaller, her dimensions being—Length, 390 ft.; breadth, 42 ft.; depth, 35 ft.; gross tonnage, 4,200 tons; and cargo capacity, 3,500 tons; with room for 1,100 tons of coal. She is fitted with ten watertight compartments. Her engines are of 800 horse-power nominal and 4,000 horse-power indicated. Accommodation is provided for 120 first-class and 48 second-class passengers. The saloon has been decorated from designs by Mr. Burgess, jun., of Glasgow. At a luncheon served in the large saloon of the *Rome*, Mr. T. Sutherland, chairman of the company, presiding, there were present, among others, Sir Louis Jackson, Sir George Chambers, Mr. Dodds, M.P., Mr. Du Plat Taylor, Mr. J. P. Knight, Mr. A. M. Bethune, secretary of the company, and Captain Cates, captain of the *Rome* and commodore of the company's fleet. Speaking of the progress of the Peninsular and Oriental Steam Navigation Company, the chairman said that in a very short time they would have a sister ship to the *Rome* in the Carthage, and before long a third of the same size to be called the *Shannon*, and three others, the *Ganges*, *Sutlej*, and *Thames*, of about the dimensions of the *Clyde*. This would make a total addition of something like 50,000 tons to their fleet. In order to keep pace with the improvements effected in ocean-going steamers they had within the last ten or eleven years sold vessels with an aggregate tonnage of about 80,000 tons, and had constructed new ships which, including those he had named, had an aggregate tonnage of 130,000 tons. When the new steamers were completed the total tonnage of the company's ships would be about 170,000 tons.

THE "CITY OF ROME."

THE steamer *City of Rome*, built by the Barrow Ship-building Company for the Inman fleet, arrived in the Mersey on the September 30th, after a series of trials in the Clyde, and has now taken her station on the line between Liverpool and New York. More than usual interest attaches to the incident owing to the fact that she is in point of capacity the largest vessel in the mercantile service and in engines the most powerful. Since her launch on June 14th, her progress has been watched with considerable interest by those concerned in nautical affairs, and though the present trials have not been as complete as was desired, they have proved entirely satisfactory so far as they have proceeded. A large company embarked on board the *City of Rome* from Greenock on Wednesday forenoon for the purpose of witnessing the trials of speed, the vessel having been taken round to the Clyde for that purpose, and for the adjustment of her compasses. The company included the Earl of Shaftesbury, Viscount Mandeville, Lord Headley, Sir James Ramsden, chairman of the Barrow Shipbuilding Company, Sir Henry Loch, Governor of the Isle of Man, Sir William Wiseman, Sir Peter Coats, Lady Edith Ashley, Mr. John Burns, chairman of the Cunard Company, and Mrs. Burns, Mr. Thomas Henderson, of the Anchor Line, Mr. C. W. Kellock, Mr. William Denny, Mr. Peter Denny, and many others interested in the construction and working of passenger steamers. A few short runs were made at easy speed, and the measured mile was covered under varying heads of steam, from easy up to three-quarter speed; but in the passage from Barrow, one of the minor bearings having become heated and fused, it was not deemed judicious to put the engines to their *maximum* power. Working at three-quarter speed, with 45 revolutions per minute, the measured mile was performed at the rate of 15¾ knots per hour; but as the engines at full speed will make 58 or 60 revolutions per minute, the trial gives assurance that the *City of Rome* will in practice attain her anticipated speed of 17½ or 18 knots per hour. In the series of tests the engines worked with great smoothness, and the readiness with which they could be manipulated is without parallel in implements of such huge dimensions. It was demonstrated by actual performance that the engines could be brought to a dead stop in two seconds by the turning of a single lever, and that from going full speed ahead they could be reversed to full speed astern in the incredible space of five seconds. The advantage of this promptness and handiness will be obvious in the event of any sudden emergency arising in the navigation of the ship. After the luncheon some of the visitors were landed at Wemyss Bay. The night was spent in cruising about Ailsa Craig for the purpose of exercising the engines, and on Thursday the progressive trials of speed were continued, with the results already stated. On Thursday evening the *City of Rome* sailed from the Clyde, running down Channel under easy steam at 14½ knots per hour, there being no desire to press the engines to their full capabilities until they had worked down to their bearings. Though there was a good breeze, she proved very steady and comfortable, as may be inferred when there was dancing in the grand saloon, which is furnished with a fine piano, while the dining saloon is fitted with a built in organ. All the principal apartments and the engine-room are lighted with the electric light (Swan's lamps), and the scene at night is brilliant as at-noonday.

In structural proportions and design the *City of Rome* presents a remarkable contrast to the *Great Eastern*, to which she stands next in magnitude in the mercantile marine. Brunel's vessel suggests the idea of a stately ark, with towering walls and ponderous hull, massive and stupendous rather than elegant. The conditions are reversed in this newer product of naval architecture. The *City of Rome* is of great length, of tapering form, symmetrical lines, and graceful mould, so that the inexperienced observer is scarcely able to realize her enormous dimensions. The difference of proportions between the two vessels supplies a singular illustration how scientific theory may be modified by practical experiment. In designing the *Great Eastern*, Brunel had no other guide than his scientific knowledge; there were no gradations between the puny vessels of five and twenty years ago and the leviathan he constructed; and he reckoned the length, beam, and depth on bases which the actual practice of later shipbuilding has not confirmed. The tendency of naval construction in the merchant navy is to lengthen the hulls, without in any appreciable degree augmenting the beam or the depth of the hold. This will be at once apparent by comparing the salient dimensions of these two typical vessels, the *Great Eastern* and the *City of Rome*. The length of the former is 680 ft., with her breadth of beam 83 ft., and depth 60 ft. The similar measurements of the *City of Rome* are, length 586 ft., while breadth of beam is 52 ft. 3 in. and her depth of hold 37 ft., so that while in length she closely approximates to her rival, in breadth and depth she is little more than half the magnitude. It is in these conspicuous differences of proportion that the disparity of tonnage is to be found. The *Great Eastern* is of enormously greater cubical capacity, as may be inferred from her breadth and depth; but, though less tall and bulky of hull, the *City of Rome* is still of great cargo capacity. Her tonnage is returned as being 8,826 tons; her displacement, on a mean draft of 26 ft., is 13,500 tons, and she has a dead-weight carrying power of 5,500 tons. The great length of the vessel and her beautifully modulated lines suggest to the beholder an impression of buoyant grace rather than of vast magnitude; yet her carrying power, notwithstanding her clipper bow, rounded stern, and trim masts, is greater than that of any other vessel afloat, except the *Great Eastern*.

This extreme length and comparative narrowness of beam might, perhaps, suggest some misgiving as to the strength of the hull. This doubt, however, is at once dispelled when the character of her construction is examined. From keel to deck the ribs and plates are of the strongest material, all knit together by angle irons and rivets, but the most distinctive feature of the design is the mode in which the hull is supported and stiffened by transverse sections. The bulkheads, of massive iron, extend from the keel upwards to the main deck, without any openings, except narrow ways, which may be closed by mechanical appliances at a moment's notice. These transverse sections serve the double purpose of strengthening the ship, much on the principle of the girder bridge, and of shutting out water in the event of accident. The largest distance between the bulkheads is only 60 ft., and it is calculated that more than one of the compartments might be filled with water without affecting the ship's flotation. The stern-post or frame is the heaviest single forging ever made for such a purpose, weighing 33 tons in the finished state. The framing of the vessel is of the ordinary type, though of exceptional size, each frame running from centre line to gunwale and being 60 ft. in length. She has two complete iron decks, with the lower deck complete for half its length; nine tiers of keelsons, the principal of which are carried in unbroken line through the engine-room; and the shell plating forms a complete skin, with every edge and butt fitted together with mechanical exactness.

The most interesting and striking feature of the vessel, however, is the engine-room. The problem the builders and engineers had to solve was how this stupendous ship, ponderous in her own weight, but still more ponderous when laden with 6,000 tons of cargo and probably 2,000 human beings, was to be propelled across the Atlantic at a speed of 18 knots an hour, that being the standard which the Inman Company set before themselves. It was an anxious and difficult study, but they are confident it has been solved. There was some thought of adopting twin screws, but it was finally determined to adhere to the older principle of a single screw, of 24 ft. diameter, driven by three sets of inverted "tandem" engines, working on three cranks, disposed at an angle of 120 deg. to each other. There are three high-pressure cylinders, 43 in. diameter, and three low-pressure cylinders, 86 in. diameter, with 6 ft. stroke. Steam is generated in eight cylindrical tubular boilers, fired from both ends, each 14 ft. diameter and 19 ft. long, the boilers being constructed for a working pressure of 90 lb. to the square inch. The engines are intended to work constantly at 8,000 indicated horse power, although capable of developing upwards of 10,000-horse power. The crank-shaft is a built shaft, and, together with the screw shaft, is made of Whitworth's fluid-compressed steel. The process of manufacture is believed to afford an absolute guarantee against flaws and blemishes. The shafts are cast in lengths, each from a hollow cylindrical ingot, which, while in the molten state is subjected to hydraulic pressure, thus excluding all gases, and consolidating the entire mass. The ingot is afterwards reheated and placed on a mandril, and is then forged and drawn by hydraulic power until it assumes the form of a double-collared shaft. The advantage of this process, according to its advocates, is, that not only is there better assurance of sound workmanship, but that the shaft is stronger and lighter; for instance, the *City of Rome's* crank-shaft weighs 64 tons, whereas, if of iron and solid, the weight would have been 73 tons.

The internal arrangements and appointments for the convenience of passengers and crew are of the most admirable character. The berths for the cabin passengers are spacious and airy, while those for the emigrants, of whom the *City of Rome* will carry an immense complement, are open, well lighted, and well apportioned. The saloons, boudoirs, smoking rooms, and drawing rooms are furnished in a luxurious style, with rich ornamentation and every appliance to render the voyage pleasant and comfortable. The vessel is, in fact, a floating palace, and though others of the great ocean-going steamers may rival her in this character, none excel her in luxury, while in capacity and engine power she is the present leader of England's mercantile marine.

The placing of this vessel on the station marks another epoch in the history of steam navigation, and illustrates the marvellous strides made in that science during the life of one British merchant. Mr. William Inman lived to see the *City of Rome* launched, but he was cut off by death a few weeks ago, before she was ready for sea. He was only 56 years of age at the time of his decease, yet during his comparatively brief life he witnessed—and, indeed, led—one of the most wonderful revolutions in maritime enterprise which history records. His boldness brought great prosperity to himself and his co-partners; but it was also attended by blessings to the world, and on the latter ground the facts deserve to be chronicled. The two main incidents of his career were that he was the pioneer in adapting the screw propeller to transatlantic navigation, and in tilizing steamships for the emigration trade.

AN ACCOUNT OF EXPERIMENTS MADE BY A BOARD OF UNITED STATES NAVAL ENGINEERS WITH SCREW PROPELLERS OF DIFFERENT MATERIAL AND DIMENSIONS APPLIED TO THE UNITED STATES FISH COMMISSION'S STEAMER "LOOKOUT" WITH THE HULL COPPERED AND NOT COPPERED.

By Chief-Engineer Isherwood, U.S. Navy.

From the Journal of the Franklin Institute.

(Continued from page 128.)

In the following Table No. 1 will be found the data of the experiments. The quantities therein given are so fully described as to need no further explanation,

The friction of the engine, *per se*, that is to say, the pressure required to work the unloaded engine, is taken at 2 pounds per square inch of the pistons of the two cylinders. The remainders of the indicated pressures, after deduction of these two pounds, are the net pressures upon the pistons.

In order to obtain a single expression for the indicated and for the net pressures, they have been reduced to what they would have been had the engine consisted of the large cylinder alone.

Explanation of Table No. 2.—(see next issue.)

In Table No. 2 will be found the distribution of the power during each of the experiments whose data are recorded in Table No. 1, the capital letters at the heads of the columns, in both tables, indicating experiments with the screws designated by the same letters.

This distribution is necessary in order to understand what portions of the indicated horses-power developed by the engine are expended in the different operations connected with the propulsion of a vessel by a screw.

Of the indicated horses-power a portion is consumed in working the engine, *per se*, that is to say, the unloaded engine; and this portion must first be deducted, because, until the friction of the engine is overcome, no power can be applied to the screw, or externally of the engine; for it is obvious, that until the friction of the engine itself is counterbalanced, the piston cannot move.

After the deduction of this power, the remainder of the horses-power, called the net horses-power, is applied to the crankpin and does external work. A friction attends the net power, additional to that of the unloaded engine and proportional to the net power, let the latter be what it may; and the power required to overcome this friction is the power absorbed by the friction of the load, the articulations of the engine moving under the net pressure producing greater friction on them than is due to the mere weight of the moving parts and to the pressure of the packings.

Then, there are the horses-power expended in overcoming the skin or surface resistance of the screw blades experienced from the water in which they move. This power can be calculated independently when the data are known.

There still remain to be determined the portions of the net horses-power expended in the slip of the screw and in the propulsion of the vessel. These are ascertained as follows: The sum of the powers expended in overcoming the friction of the load and in overcoming the resistance of the water to the surface of the screw blades being deducted from the net horses-power, the remainder is divided between the power expended in the slip of the screw and in the propulsion of the vessel in the ratio of the speeds of the two; the pressure exercised by the screw forward in propelling the vessel, and backward upon the receding mass of water, constituting the slip of the screw, being the same. Hence, if the aforesaid remainder of power be multiplied by the speed of the slip expressed in fractions of the axial speed of the screw, the product will be the power expended in the slip, which being subtracted from the above remainder leaves the residue as the power expended in the propulsion of the vessel.

On these general principles, the corresponding quantities in Table No. 2 have been calculated. For facility of reference, the quantities have been grouped and the lines containing them numbered.

Line 1 contains the dates of the experiments. Line 2 gives the speeds of the vessel per hour, in geographical miles of 6086 feet. Line 3 gives the slips of the screws in per centum of their speed, calculated from their pitches into the number of their revolutions made per hour, and from the speeds of the vessel on line 2. On line 4 are the thrusts of the screws in pounds during each experiment; these quantities are what would have been given by a dynamometer had one been applied directly to the screw shaft and fulcrumed on the vessel. They are calculated from the quantities on line 19, by multiplying the latter by 33,000 and dividing the product by the speed of the vessel in feet per minute. Line 5 contains the number of double strokes made per minute by the pistons of the engine, and of revolutions made per minute by the screw. The quantities on lines 1, 2, 3 and 5 are taken from Table No. 1 and added for the sake of completeness to Table No. 2.

Distribution of the Indicated Horses-Power.

Lines 13 to 19, both inclusive, show the distribution of the indicated horses-power among the operations contingent on the propulsion of the vessel by the experimental screws. Line 13 contains the indicated horses-power, the quantities being taken from Table No. 1; and line 15 contains the net horses-power applied to the crankpin, also taken from Table No. 1. Line 14 contains the horses-power expended in working the engine, *per se*, or unloaded, the quantities being the difference between those on lines 13 and 15; they can, however, be obtained independently by calculation, the data being the speed of the piston per minute in feet obtained from line 5, the area in square inches of the piston of the large cylinder alone, and the pressure on line 7. Line 16 contains the horses-power absorbed by the friction of the load; these quantities are obtained by multiplying those on line 15 by 0·075, that fraction being the coefficient of the friction of the load. Line 17 gives the horses-power expended in overcoming the resistance of the water to the surface of the screw blades. These quantities have been calculated on the assumption that a square foot of the helicoidal surface of the screws, moving in its helical path with a speed of 10 feet per second, has a resistance of 0·45 pound, which resistance increases or decreases in the ratio of the square of the helical speeds. Line 13 contains the horses-power expended in the slips of the screws, these quantities are calculated by multiplying the remainders of the quantities on line 15 after subtraction of the sum of the quantities on lines 16 and 17, by the quantities on line 3 expressed in fractions of the axial speeds of the screws. Line 19 gives the horses-power expended in the propulsion of the vessel, which power is all that is utilized of the entire power developed by the engine. The quantities are the remainders of those on line 15 after subtraction of the sum of the quantities on lines 16, 17 and 18.

Distribution of the Indicated Pressure on the Piston.

Lines 6 to 12, both inclusive, show the distribution of the indicated pressure. A single expression for this pressure being necessary, and the engine having two compounded cylinders—a small one and a large one—the desired single expression was obtained by reducing the experimental indicated pressure per square inch on the piston of the small cylinder, in the ratio of the areas of the pistons of both cylinders, and adding the quantity thus obtained to the experimental indicated pressure per square inch on the piston of the large cylinder. These are the quantities on line 6, and are taken from Table No. 1. Line 7 contains the pressure per square inch of the large piston alone, required to work the engine, *per se*. With both cylinders in use, this pressure was taken at two pounds per square inch of the pistons, and the equivalent, if applied to the piston of the large cylinder alone, was obtained by dividing 2 by the ratio of the areas of the two pistons and adding the quotient to 2, which produced the constant 2·7164 pounds per square inch, for the piston of the large cylinder alone, on line 7. Line 8 gives the net pressures applied to the crankpin, in pounds per square inch of the piston of the large cylinder alone; these quantities are the remainders of those on line 6 after subtraction of those on line 7. Line 9 contains the pressures, per square inch of the piston of the large cylinder alone, absorbed by the friction of the loads; these quantities are the products of those on line 8 by the fraction 0·075 which is the coefficient for the friction. Line 10 contains the pressures per square inch of the piston of the large cylinder alone expended in overcoming the resistance of the water to the surface of the screw blades. These quantities are the same proportion of those on line 8, that the quantities on line 17 are of those on line 15. Line 11 contains the pressures per square inch of the piston of the large cylinder alone expended in the slip of the screw. These quantities are the same proportion of those on line 8, that the quantities on line 18 are of those on line 15. Line 12 contains the pressures per square inch of the piston of the large cylinder alone, expended in the propulsion of the vessel. These quantities are the same proportion of those on line 8, that the quantities on line 19 are of those on line 15. Or, the quantities on line 12 are what remain after subtraction from those on line 8 of the sum of the quantities on lines 9, 10, 11 and 12.

The quantities on lines 20, 21, 22 and 23 are the per centum, respectively, which the quantities on lines 16, 17, 18 and 19 are of those on line 15. The quantities on lines 20, 21, 22 and 23 are also the per centum, respectively, which the quantities on lines 9, 10, 11 and 12 are of those on line 8. The quantities on lines 20, 21, 22 and 23 show, centesimally, the distribution of the net pressure and of the net power applied to the crankpin.

The quantities on line 23 express the relative utilizations of the experimental screws; that is to say, they express the per centum of the net power applied to the crankpin which the screws apply to the propulsion of the vessel. These utilizations are correct if the distribution of the net power be correct, but not otherwise. It is, therefore, of importance that the relative utilizations of the screws be obtained directly from data devoid of doubt. The quantities on line 24 express such results, and are obtained by dividing the cubes of the speeds of the vessel on line 2 by the net horses-power applied to the crankpin—line 15. The cube of the speed of the vessel expresses the useful work done, and the net horses-power expresses the power expended in doing it; the latter divided into the former gives the work done *pro rata* to power expended, therefore the larger the quotients of the divisions, that is, the larger the quantities on line 24, the greater will be the utilizations of the screws.

The quantities on line 24 afford the means of demonstrating whether the distribution of the power is correct; if it be, then the quantities on line 23 will have the same ratio to each other that the quantities on line 24 have to each other. To find if this equality exists, the quantities on line 24 were divided into those on line 23, and the quotients are given on line 25. If these quotients were equal, then the distribution of the power would be exact; if unequal, it is inexact to the extent of the inequality. When these quotients are examined, there must be recollected that they consist of two sets—one for the uncoppered hull (columns *A*, *B*, *C*, *D* and *E*), the other for the coppered hull (columns *F* and *G*); consequently, the equality referred to must be looked for only between the experiments of each set.

The fact that in the experiments with the coppered hull, its resistance was less than when it was uncoppered, makes its speed higher with a given net power than when uncoppered; and the quotients of the division of the cubes of the speeds of the vessel by the net horses-power will consequently be higher with the coppered than with the uncoppered hull. These higher quotients (experiments *F* and *G*, line 24) divided into the corresponding utilizations, or quantities on line 23, give accordingly less results on line 25 for experiments *F* and *G* than for the remaining experiments.

The near equality of the quantities on line 25 for experiments *A*, *B*, *C*, *D* and *E* with the uncoppered hull, and for experiments *F*

SCREW EXPERIMENTS.

and *G* with the hull coppered, prove the principle and the constants employed in calculating the distribution of the power to be correct. No nearer approach to equality than these quantities present could be obtained from delicate laboratory experiments. With this confirmation, the data and results of these screw trials may be accepted as absolutely exact.

(*To be continued.*)

ON THE PROGRESS AND DEVELOPMENT OF THE MARINE ENGINE.*

By MR. F. C. MARSHALL, of Newcastle-on-Tyne.

(*Continued from page* 157.)

WEIGHT.—The weight of machinery, water, and fuel carried for propelling ships has not had due attention in the general of engineers.

By the best shipping authorities the writer is assured that every ton of dead weight capacity is worth on an average £10 per annum as earning freight. Assuming, therefore, the weight of the machinery and water of any ordinary vessel to be 300 tons, and that, by careful design and judicious use of materials, the engineer can reduce it by 100 tons, without increasing the cost of working, he makes the vessel worth £1,000 per annum more to her owners. That there is much room for improvement in this direction is shown by the following statement, giving, for various classes of ships, the average weight of machinery, including engines, boilers, water, and all fittings ready for sea, in pounds per indicated horse power:

	Pounds per I.H.P.
Merchant steamers	480
Royal Navy	360
Engines specially designed for light draught vessels	280
Royal Navy, *Polyphemus* class (given by Mr. Wright)	180
Modern locomotive	140
Torpedo vessels	60
Ordinary marine boilers, including water	196
Locomotive boilers, including water	60

In view of the commercial considerations before-mentioned, in regard to merchant steamers, these figures confirm the idea that the weight of machinery on board such vessels has not received the attention its importance demands.

The ordinary marine boiler, encumbered as it is by the regulations of the Board of Trade and of Lloyd's Committee, does not admit of much reduction in the weight of material or of water carried when working. The introduction of steel has reduced the weight by about one-tenth; but it will be the alteration of form, to the locomotive, tubulous, or some other type, combined with some method of forced draught, to which we must look for such reductions in weight of material and water as will be of any great commercial value.

The engine may be reduced in weight by reducing its size, and this can only be done by increasing the number of revolutions per minute. It has hitherto been the practice to treat the propeller as dependent upon the size of engines, draught of water, and speed required. This process should be reversed. The propeller's diameter depends on the column of water behind, necessary to overcome the resistance in front of it due to the properties of the vessel. This fixed, the speed will then fix the number of revolutions, which will be found much greater than is usual in practice; and from this the size of the engines and boilers will be determined.

Great saving in weight can be effected by careful design, and judicious selection and adaptation of materials; also by the substitution of trussed framing and a proper mode of securing the engine to the structure of the vessel, as worked out in H.M.S. *Nelson*, by Mr. A. C. Kirk, of Glasgow, Fig. 13, and in the beautifully designed engines of Mr. Thornycroft, Fig. 14, in place of the massive cast-iron bedplates and columns of the ordinary engines of commerce. The American engines of the earlier time might also be profitably studied, not for imitation throughout, but to see what can be done towards lightening machinery, and at the same time securing efficiency and durability. Condensers may be profitably made of plate iron, brass, or copper, due care being taken to guard against galvanic action. The condensing surface needs further consideration; in many cases it is much larger than necessary; in which case massive castings of great weight are required, and large quantities of water carried, which are not really needed.

The same may be said of the moving parts. Solidity and rigidity are great virtues in a stationary engine or machine, and weight is necessary to the locomotive for the purpose of adhesion; but in the case of a marine engine mass and rigidity may, and frequently do, become serious evils. Firstly, unnecessary mass means needless weight to be carried, unprofitable load to be propelled, and the displacement of its equivalent in freight-paying cargo; and, secondly, it means rigidity, and the setting up of a state of heterogeneity in the whole structure, consisting of ships, engines, and cargo, instead of the homogeneity which is essential to a successful working machine. In fine, the hull and engine should be as much as possible one structure; rigidity in one place and elasticity in others is the cause of most of the accidents so costly to the shipowner; under such conditions mass and solidity cease to be virtues, and the sooner their place is taken by careful design, and the use of the smallest weight of material (of the very best kind for the purpose) consistent with thorough efficiency, the better for all concerned.

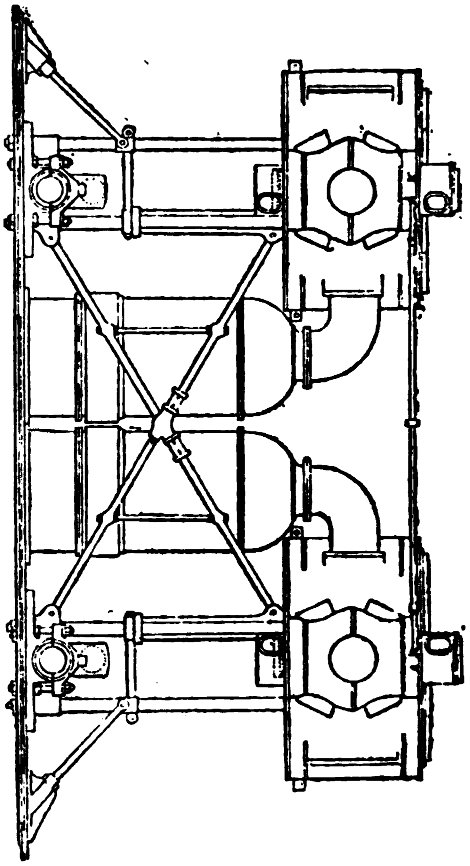

Fig. 12.

Fuel.—We come now to the question of the consumption of fuel. Referring again to Table I., we see that a considerable saving has been effected in nine years. The averages of Sir Frederick Bramwell's Table and of Table I. stand as in Table II.

This shows a saving equal to 13·38 per cent. in quantity of fuel consumed. It is right to mention that the percentage here stated by no means represents the actual saving effected in money value. The coal now supplied to steamers is of very inferior quality compared with that shipped as bunker coal prior to the coal famine of 1873 and 1874. During these years the refuse of the pits and pit heaps, and the poorest of black material, came into use, and this still holds its place firmly as bunker coal; at best, unscreened coal is supplied, where the very best screened coal was required prior to

---

1873. This very materially affects the question in hand, and the writer submits that it would not be unreasonable to take credit for a saving in money value of at least 20 per cent.

TABLE II.—*Comparison of* 1872 *and* 1881.

Item.	1872.	1881.
Working pressure, lbs. per sq. in.	52·5	77·4
Heating surface per I.H.P., sq. ft.	4·64	3·919
Piston speed, ft. per min. ...	376	467
Coal burnt per I.H.P., lbs. ...	2·11	1·828

The writer thinks it right to introduce at this point a letter with which he has been favoured by Mr. Alfred Holt, of Liverpool, bearing on this subject, as well as on other matters with which he will deal presently.

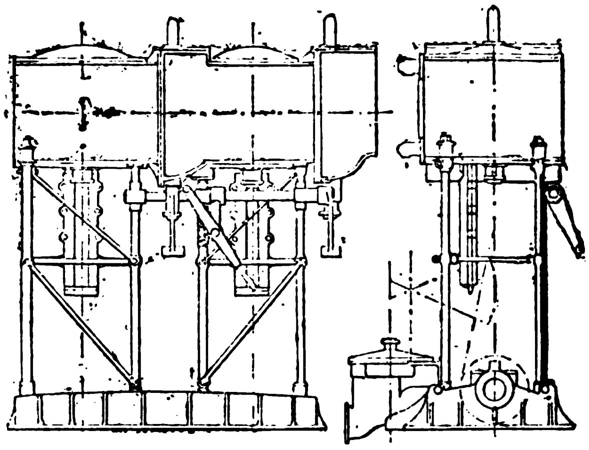

Fig. 13.

"1, India Buildings, Liverpool, June 18, 1881.

"Dear Sir,—In response to your letter of May 27, I now enclose the form you sent me, filled up with particulars of specimens of two of my best classes of ships. My vessels run in classes, so there is no occasion to give you particulars of individual ships.

"I do not think that quite so good a result as that shown in the form is generally attained on the average through the fleet; and having commenced lately to allow more steam in the high-pressure cylinders, a less economical performance naturally results.

"I think I should be able to obtain about 2·3 lb. per indicated horse power per hour over the whole, and I do not think that I have made anything more than a fractional advance in economy of fuel since 1868.

"The fact of the matter is I have not tried to do so, and I don't believe, so far as my observation extends, that mere economy of fuel is much cared for now; coals, which used to be the greatest, are becoming one of the minor disbursements of a steamer, and it cannot have escaped your notice that some modern steamers, careless of fuel, are actually abandoning both the compound system and high pressure.

"My opinion is, and for many years has been, that the compound system will come to be abandoned. I am endeavouring to feel my way to using the steam in one cylinder only, and so far the results have been encouraging; and I am now engining a 2,200-ton vessel on that system. I am also endeavouring to do without a crankshaft, the forward end of the screw-shaft carrying an ordinary crank with overhung pin. This experiment also, so far as I have got, promises satisfactorily (see illustrations next number).

"In my opinion the great improvement of the immediate future is to increase the steam production of our boilers. A ton weight of a locomotive boiler produces as much steam as 6 tons of an ordinary steamboat boiler.

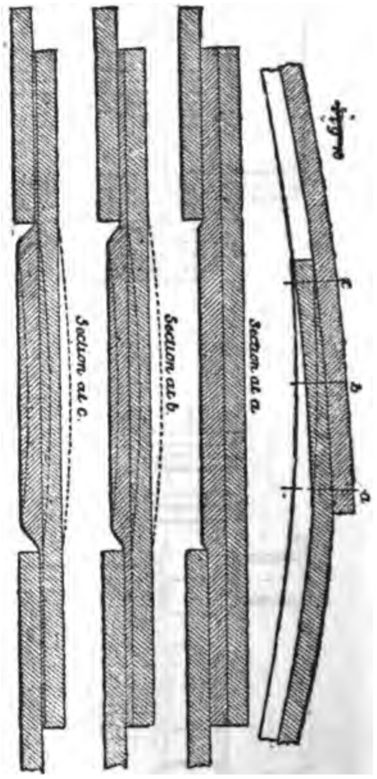
"Of course the solution lies in the possibility of (1) burning more fuel, and (2) taking the heat out of it. It is a difficult problem; a steam blast will not do it, and I am fitting a vessel with a rotary blower capable of a pressure of about 2 lb. on the inch, which shall eject air through a tapered blast pipe up the centre line of an ordinary funnel, so near the top that, before the cold ejected air destroys by its gravity the motive force it has received from the blower, and so deadens the current, it shall be out of the chimney. At the present time I am more hopeful than confident of the result, but I am convinced improvement in that line is shortly to be looked for. What a gain it would be to diminish the weight of our boilers to one-third, which is my aim in the boat alluded to.

"Yours truly,
"ALFRED HOLT.

"F. C. Marshall, Esq., Newcastle-on-Tyne."

This letter the writer considers one of great importance, coming as it does from one of our most enterprising shipowners, who is at the same time an experienced practical engineer.

It will be noticed Mr. Holt speaks of the coal account as one of the minor disbursements of a steamer. He does not give us the ratio which coals bear to the total disbursements, but from other reliable sources the writer finds that, according to the direction of the voyage, it varies from 16 to 20 per cent.—or say an average of 18 per cent.—of the total disbursements, in a vessel carrying a cargo of 2,500 tons. This will represent to-day about £3,000 per annum, and in 1872, at equal prices, the cost would have been £3,750—showing a saving of £750, equal to a dividend of say 3 per cent. on the value of the ship. Again, the cost of coal per mile run for such a vessel in 1872 would have been at least 16½d.; to-day it does not exceed 13d.

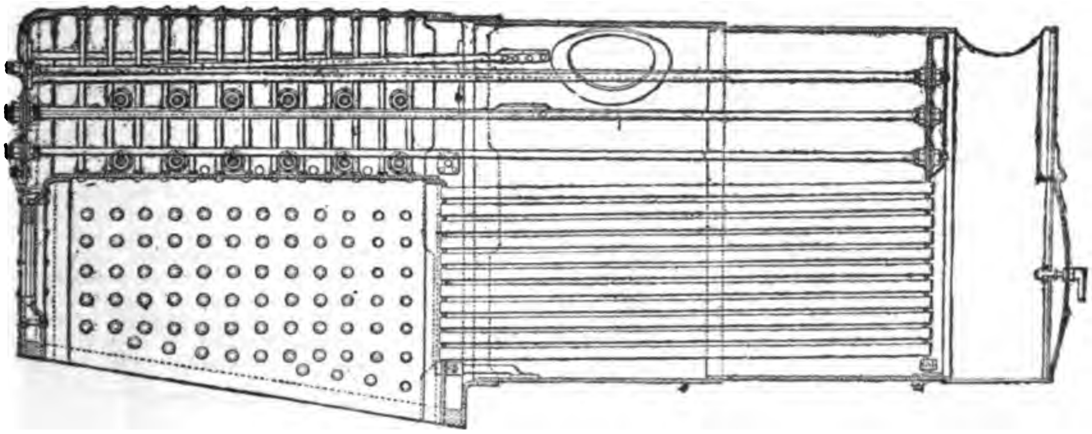


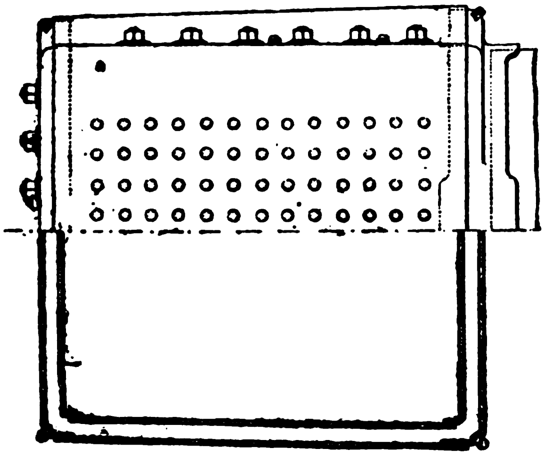
See page 155.

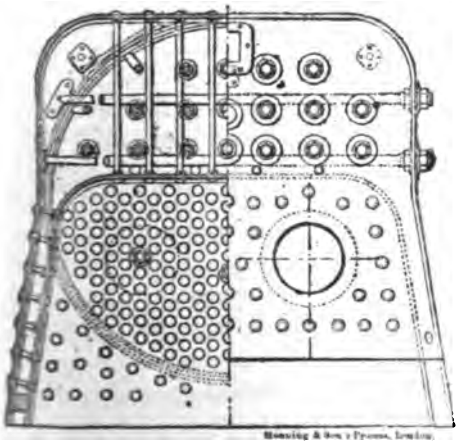
Viewed from the shipowners' stand-point this may be a minor consideration, but to the marine engineer it is important as indicating progress where progress is difficult, and taking it as such he is encouraged to further effort in the same direction.

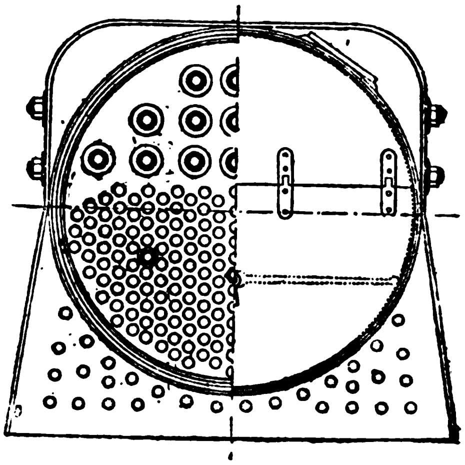
Efficiency.—The third part of this question must now be considered, viz., how to increase speed and power with safety and efficiency.

The marine boiler as now made is a very efficient machine. Tables I. and II. show that, with an increase of pressure, consumption has been reduced; but if the quantity of steam used be considered, in relation to the increased pressure, it will be seen that the boiler of to-day is little, if any, more efficient than that of ten years ago; as is shown by the following comparative Table of the calculated advantage due to using steam of the average working pressure given in Table I., or 77·4 lbs. over the average pressure of 1872, namely, 52·5 lb.









Menning & Son's Process, London.

See page 155.

The advantage is seen to be 13 per cent., which is almost exactly the same as the actual saving given in Table I., from which it would appear that our gain in consumption is solely due to higher pressure, and in no sense to increased efficiency of boiler.

TABLE III.

Calculated Net Coal and Steam used per Indicated Horse Power, for Steam of 52·5 lb. and 77·4 lb. Pressure; the same Terminal and Back Pressure being assumed in each case.

——	Effective Pressure, 52·5 lb.	Effective Pressure, 77·4 lb.
Working pressure (total) ... lb.	67·5	92·4
Number of expansions	5·15	7·0
Steam used per indicated horse power per hour ... ... lb.	21	18·17
Net coal required, per indicated horse power per hour ... lb.	1·73	1·501
Ratio of the net coal required, the amount for 67·5 lb. being unity	1	0·87
Coal per indicated horse power, taking 2·11 lb. as required at 67·5 lb.	2·11	1·835
Actual coal burnt, per Tables ...	2·11	1·828

If the evaporative performance of the marine boiler is to be increased, it must be by one of the four following methods: (1) Increase of heating surface; (2) better disposition of absorbing surface; (3) the adoption of thinner plates, or of a material having better conductive power for heat; (4) the adoption of a different and better form of boiler as a whole.

The present boiler has an evaporating efficiency of about 75 per cent., and cannot be much improved so long as air is supplied to the furnace by the natural draught, due to the temperature and height of chimney. The extent of efficient heating and grate surface is limited, and almost fixed, by the same cause.

To increase the efficiency from 75 to 82·5 per cent. would require about double the heating surface, the weight of boiler and water being also doubled, while the gain would only be 10 per cent. If it were attempted at the same time to increase the pressure, as well as the surface, relatively to the coal burnt, the addition would be somewhat less; thus, were there an increase of pressure from 105 lb. to 150 lb., then instead of double the quantity of heating surface, 1·75 of that due to the lower pressure would suffice.

Mr. Blechynden's formula, used in the writer's works for weights of cylindrical marine boilers of the ordinary type, and for pressures varying from 50 lb. to 150 lb. is as follows:

$$W = \frac{(P + 15)\,(S + D^2 L)}{C};$$

or

$$W = \frac{2\,S\,(P + 15)}{C}$$

when $S = D^2 L$, which is a common proportion.

Here W = weight in tons.
P = working pressure as on gauge.
S = heating surface in square feet.
D = diameter, in feet.
L = length in feet.
C = a constant divisor, depending on the class of rivetting, &c. For boilers to Lloyd's rules, and with iron shells having 75 per cent. strength of solid plate, $C = 13{,}200$.

This formula, if correct, and it is almost strictly so, would give the relative weight of boilers per square foot of heating surface, for 105 lb. and 150 lb. total pressure, assuming we wish to increase the efficiency 10 per cent. as follows:

$$\text{Weight at 105 lb.} = 105 \times \frac{1}{C}$$

$$\text{,, } \quad 150\text{ lb.} = 150 \times \frac{1{\cdot}75}{C} = \frac{263}{C}$$

$$\text{Hence the ratio of weight} = \frac{263}{105} = 2{\cdot}5.$$

In other words, the boiler with the higher efficiency would weigh two and a half times that with the lower efficiency. It appears, therefore, that increase of efficiency cannot be got to any useful extent by increase of surface, without such serious addition to weight as to render it impracticable, or at least unprofitable.

Next, will better disposition of heating surface, or the adoption of thinner or more conductive material, add to the evaporative efficiency?

It is difficult to see in what way much departure can be made from the present arrangement of surface. The introduction of the Fox corrugated furnace is the only step made of late years, and it promises in the future to be an effective form in which to place the material. Hitherto there have been difficulties connected with its use, but these have been in every case due to manufacture, and such as are incident to every new process. They have in no case arisen from the principle of corrugation, which must in time permit the furnaces, the best and most vital of the effective parts of the boiler, to be made of considerably thinner plate; and will thus increase to some extent the efficiency of the boiler. The use of metal of higher conductivity for the flame boxes and tubes, say copper for the one and brass for the other, would undoubtedly add greatly to the efficiency of these parts. The boilers of the Navy are invariably fitted with brass tubes, and but for the first cost of the material, and subsequent outlay for zinc, to prevent galvanic action in the iron, it would be a gain to adopt them generally.

(*To be continued.*)

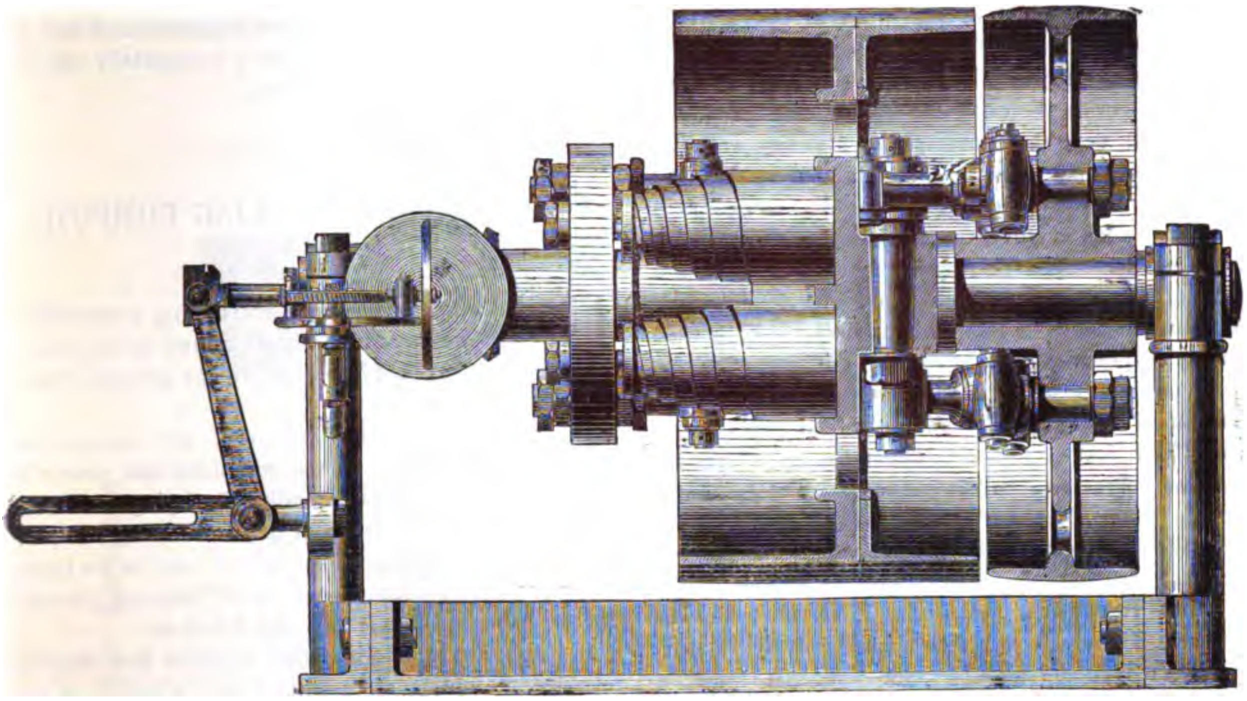
BOURRY'S DYNAMOMETRICAL GOVERNOR.

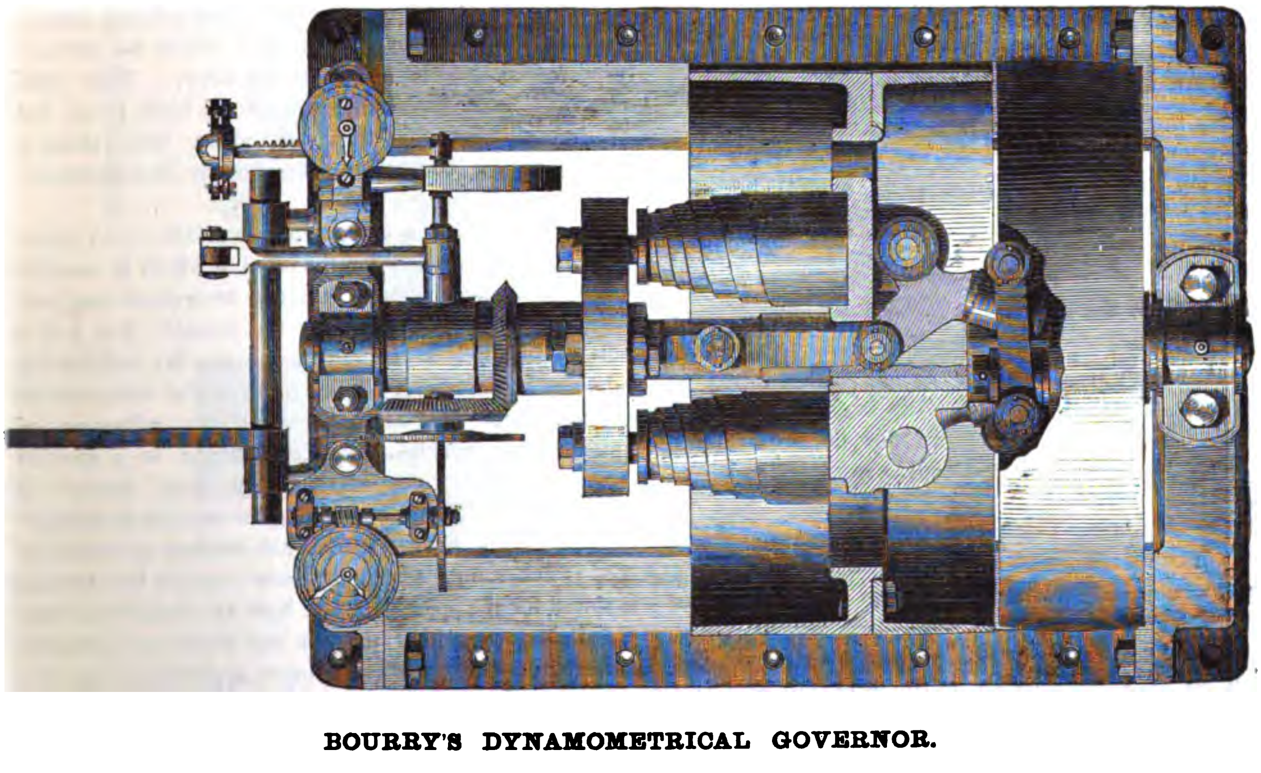
THERE are two great desiderata for the good regulation and easy working of any marine engine. The first of these is a governor which will check racing before the propeller leaves the water. The other is an elastic connection between the engine and propeller shaft.

The ordinary pendulum governor, or any other which depends upon a change of centrifugal force for its action, is perfectly incompetent to properly regulate a marine engine. This is obvious when the point is realized that to check racing the steam must be altogether cut off before there is any very sensible increase of speed. There is always sufficient steam remaining in the steam chest, cylinder and pipes, after the steam has been shut off, to enable the engine to run on whilst the propeller is out of water.

There are a few governors only, which are at present little used, that will effect such a preliminary regulation of the engine before racing has occurred. The present largely used plan for the engine to be watched and controlled by the attendant engineer, is exceedingly unmechanical and unworthy of our mechanical skill. Under the second head of an elastic medium between the engine and the propeller one or two plans have already been suggested, one in particular by Mr. Hamilton Pendred, but we do not know that they have ever been put into practical operation. The value resulting from such an apparatus must be very great, and the serious and frequent break downs of propeller shafts are invariably due to continued or sudden shock between the engine and propeller.

The inventions of Mr. Bourry, a Swiss engineer, and which we herewith illustrate, seem admirably calculated





BOURRY'S DYNAMOMETRICAL GOVERNOR.

to effect by the one apparatus both of the objects we have referred to.

Mr. Bourry's idea is essentially to convert the actual torsional resisting strain of the propeller into a direct pull in the line of the shaft. Springs of any convenient form can be inserted in this tensional pull so as to make elastic connection between the engine and propeller. At the same time the movement of a sliding collar or sleeve, not rotating with the shaft and moving with the moving end of the springs, can be utilized to operate a governor. Such a governor would gradually shut off steam as the strain decreased before any increased speed of the propeller could have developed itself. The movement also of this dynamo clutch can be used to operate dynamical indicating gear.

The mechanism for effecting this purpose is shown, in elevation and plan respectively, in our two illustrations. The first shows the apparatus as suited for stationary engine and factory purposes. The apparatus is here in the form of a counter-shaft mounted on independent pedestals and frame. One pulley (the narrowest) receives the power from the engine, whilst the other (the widest) transmits it to the plant or machine. These pulleys are connected only by a clutch. The clutch is in the form of links attached to pins on the arms of the driven pulley, which communicate the strain to bell cranks pivoted on the arms of the other pulley. The angle of each bell crank is attached to a fixed point on the driven part of the shaft by a volute spring, which enables the bell to give according to the strain. The second illustration shows the apparatus inserted in the line of the main shaft itself, as would be the case in the propeller shaft of a marine engine. A double crank is keyed to that part of the shaft bearing the propeller, and to the pins are attached two links connected to bell cranks, plainly seen in the plan. The bell cranks are centred on a fixed collar, and the other ends thrust by a pair of links upon another sliding disc on the shaft. These two collars or discs are connected by spiral springs of suitable strength. The action of the bell cranks under the torsional strain is thus to force the two discs apart, which is resisted by the action of the spiral springs. Any variety of resistance offered by the propeller is thus transmitted through the springs. There can thus be no possibility of shock in the propeller shaft or communicated to the engine.

From the sliding disc a combined rotation of a plate and a reciprocating movement is utilised to produce a variable speed of rotation of another disc, which can be used for the indication of the dynamometrical effect. At the same time a counting apparatus may be easily fitted so as simultaneously to indicate the speed of revolution.

Such an apparatus would give a most perfect and constant indication of the nett effort of an engine, and would thus at all times be a most valuable indicator. The whole arrangement is most ingenious and can be constructed of such strength that it is especially suitable for use in marine propeller shafts.

FOULGER'S ANTI-FOULING COMPOSITION.

THE value of a really good anti-fouling composition to the owners of iron vessels cannot be too highly estimated. This subject requires the personal attention of ship owners.

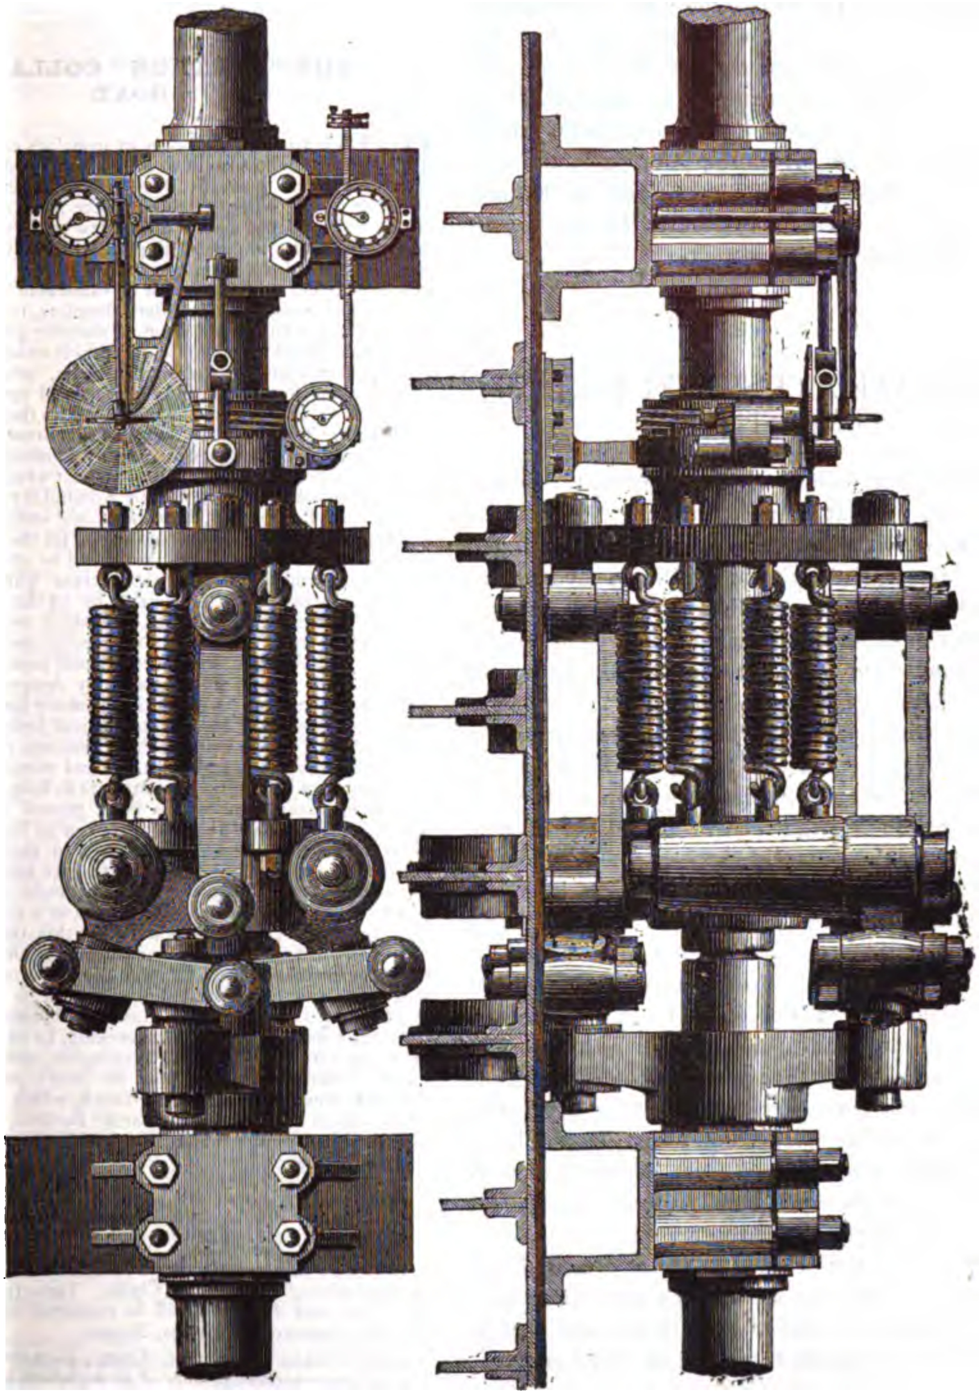
In the manner of application of any composition which they are inclined to test, too much care cannot be taken by them in superintending the laying on of such compositions, as the action of any anti-fouling composition can be entirely ruined by want of care in the laying on of the relative coats, and in the properly dry condition of the hull before any coat is laid on.

In pursuance of our intention to draw the different reliable anti-fouling compositions to the notice of our readers, we now direct their attention to Foulger's improved, formerly known as Vian's patent ferro-manganesic composition, as manufactured and supplied by Messrs. John Foulger & Sons, of Lime Street, E.C., who are the sole proprietors.

The value of this composition is, we believe, already generally known, some trials with which we are acquainted dating back as far as 1870. The chief objection to it has hitherto been its high price, but as the value of the chief ingredient has steadily decreased the composition has latterly been considerably lowered.

Messrs. Foulger's composition is divided into three different descriptions—1st, the priming which is essentially an anti-corrosive paint designed to prevent rust, and thus to protect the plates of the vessel. No. 3 is a purely anti-fouling composition with the exfoliating qualities so necessary. This part of the composition is constituted so as to prevent the adhesion of animal or vegetable substances. No. 2 is a species of intermediate composition, partaking partly of the qualities of No. 3, but having the especial characteristic of drying hard. It does not exfoliate so freely as No. 3, but stands scrubbing better, and for this reason is suited for the space between light and deep load line.

It is important that the iron hull should be perfectly clean and dry before the priming is applied, and equally necessary that each coat should be thoroughly dry before the following one is applied.



BOURRY'S DYNAMOMETRICAL GOVERNOR.

We find this firm have already supplied the composition largely to the Royal Mail Steam Packet Company for their inter-colonial vessels in the West Indies. As it is well known that these ports are most injurious in the matter of fouling and corroding of the hulls of iron vessels, it is therefore a proof of the exceptionally excellent character of the composition that it has under those circumstances given the best satisfaction. The application has also been largely made to ships of the Union Steamship Company, and it is reported that the fastest voyage ever made in that line was made by a vessel coated by Messrs. Foulger's anti-fouling composition.

VAN SPEYBROUCK'S ANTI-FOULING COMPOSITION.

ANOTHER anti-fouling composition that deserves attention is that manufactured by Messrs. Van Speybrouck, of Belgium. The agents for the United Kingdom, Messrs. Noldwritt and Murray, favoured us with a letter, which we published in our last issue, referring to a most successful trial of their composition. We can sympathize with them in the difficulty they have experienced in making shipowners grant an opportunity for a trial, but as the latter are realizing to a greater degree the necessity for a good anti-fouling composition, we should imagine they would now be more prepared to test the relative advantages of rival compositions for themselves.

The material recommended by this firm is homogeneous in its character and not of two or more diverse coatings. This, so far, simplifies the application of the paint, that there can be no confusion of coatings in the order of laying on. The coating is elastic, and will neither crack, chip, nor peel. It dries quickly, which is of considerable importance as a question of time, and also insuring that successive coats shall be dry before the laying on of the following one. It absolutely protects both iron and wood from decomposition or oxidation, and, at the same time, prevents all vegetable growth and the adhesion of barnacles.

We see, in the letter referred to, from Messrs. Noldwritt and Murray that the Admiralty's preliminary tests were spread over a period of three years, and that in the case of the composition applied in October, 1878, and redocked in April, 1880, it was found that the iron was thoroughly preserved and the bottom free from vegetation.

The coating is far better known in Belgium than in England as yet, and it has been largely used by the Belgian Government. It is cheap compared with other anti-fouling compositions, so much so as to render it suitable for painting funnels and the interior of iron ships, jetties, or any iron work specially liable to corrosion.

THE "BERTHON" COLLAPSIBLE BOAT.

RECENT trials of the boats of ironclads carrying guns of from 34 tons to 80 tons in weight have proved that ordinary boats are often, if not generally, damaged by the exhaustion of air produced by each discharge. Some of the boats of the *Neptune* were in this way rendered useless after a few rounds. But there is a far more formidable danger to ships' boats in action arising from the machine guns of the enemy, by which, (firing, as they do, a perfect stream of balls) everything that is vulnerable must be riddled in the first five minutes. In order, therefore, to provide boats that would withstand the concussion of monster guns, a 26 ft. folding galley was placed on board the *Neptune* in exactly the same position previously occupied by the wooden boats, which were destroyed; and on being shut up, whereby it presented very little surface to the disturbed air, it was found to withstand all the effects of the heavy discharges. But the other danger—that from the fire of machine guns—remained, though considerably diminished by the reduced dimensions presented by the Berthon boat when collapsed. It was then suggested to Mr. Berthon by Admiral Ryder, the Commander in-Chief at Portsmouth, that he should endeavour to provide for the big ships as he had already done for the torpedo launches—viz., construct for them boats that could be stowed under hatches and behind armour. The perfect success which has attended the bipartite dingeys which are carried by all the torpedo launches of England, France, and Austria, and which are to be supplied to those belonging to the Italian navy, encouraged the idea of making a large 31ft. cutter in three sections and capable of being stowed below. Such a craft was accordingly designed and built by Mr. Berthon at the company's works at Romsey for the *Inflexible*, and was placed on board the turret-ship just before she left Spithead for the West. It is built in three sections, each forming a complete folding lifeboat, and quite safe and seaworthy by itself. The dimensions of the entire boat are—31 ft. long, 8 ft. 3 in. wide, and 3 ft. 10 in. deep, and it has been proved capable of carrying upwards of 60 men with safety. It can be launched either united or in three parts and connected afloat, so that, should any injury occur to any one section, the other two are still available. Should the middle section, for instance, be destroyed, it could be detached, and by uniting the bow and stern sections a perfect though shorter boat be formed. In addition to all this, the entire body of the boat is divided into 24 separate watertight air cells, which render it insubmergible. The admirable behaviour of this boat in a very nasty sea was demonstrated in going out to Spithead, when Mr. Berthon was on board. Having obtained orders from the Admiralty only on the previous evening, he proceeded with a crew of 16 men from the Duke of Wellington, and soon encountered heavy, broken sea, which tried the boat's powers to perfection. Taken in tow by a large steam launch, which was swept fore and aft by almost every sea, the tripartite *Berthon*, with a long tow-line did not ship a pint of water, thus proving herself one of the driest crafts in existence.

FOUR new iron vessels are to be constructed for the Admiralty by shipbuilding firms on the Clyde. Three (named the *Misletoe*, *Watchful*, and *Arbacore*) will be entrusted to Messrs. Elder, and one (the *Arethusa*) to Messrs. Napier.

KAHNWEILER'S PATENT CORK JACKET.—The magnificent Inman Line steamer the *City of Rome*, which left the port of Liverpool on her first trip to New York, has on board 300 of Mr. Kahnweiler's cleverly-constructed cork life preservers, which have been supplied by Messrs. Watly & Co., of Preeson's Row, Liverpool, who are, we understand, the sole agents for Great Britain. The requirements of a life-belt are buoyancy, ease of adjustment, and the impossibility of displacement. These requisites are contained in this clever American invention, whilst the cost is about one-half of the ordinary life-belt.

LAUNCHES AND TRIAL TRIPS.

We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of THE MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Olivebranch.—On September 24th the second of two screw-steamers built to the order of Messrs. F. and W. Ritson, Sunderland, was launched from the yard of Messrs. William Doxford & Sons, Pallion. The steamer is 260 ft. in length, 36 ft. wide, and 18½ ft. in depth. She is both built and engined by Messrs. Doxford, has 33-in. by 62-in. cylinders, 42-in. stroke, is classed A 1, and will carry 2,200 tons deadweight. The vessel was christened the *Olivebranch.*

Reginald Hanson.—On September 24th Messrs. Short Brothers launched from their shipbuilding yard at Pallion, Sunderland, a screw-steamer, built to the order of Messrs. G. E. Wood & Sons, 30, Coal Exchange, London. The vessel is of the following dimensions:—Length, 216 ft.; breadth, 30 ft.; and 16 ft. 5 in. depth of hold, with a deadweight carrying capacity of 1,400 tons. She is constructed with a long raised quarter-deck, bridge-house over engine and boiler-room amidships, and topgallant forecastle, iron deck, water ballast, all fore and aft. She is intended for the general trade. The vessel was named the *Reginald Hanson.*

Ebbw Vale.—On September 24th there was launched from the Willington Quay yard of Palmer's Shipbuilding and Iron Company (Limited) a screw steamer, built to the order of Messrs. Morrell Brothers & Co., Cardiff. The vessel is 250 ft. in length over all, 33 ft. broad, and 18 ft. deep. She will be fitted with Palmer's engines, of 130-horse power nominal, and Emerson Walker & Co.'s patent windlass. The vessel was christened the *Ebbw Vale* by Miss Davidson.

Bretwalda.—On September 24th there was launched at Jarrow a steamer built for Messrs. Hall Brothers, of Newcastle. The dimensions are:—Length (over all), 330 ft.; breadth of beam, 39 ft.; depth of hold, 29½ ft. The vessel is so constructed that her decks are covered in from end to end, the upper deck being surrounded by an open rail; whilst she will have a freeboard of fully 10 ft. The steamer was christened the *Bretwalda.* She will carry about 3,600 tons, and will be propelled by powerful engines. The ceremony of naming the vessel was performed by Miss Hall, daughter of Mr. James Hall, one of the owners.

Empire.—On September 24th there was launched from the buildingyard of Messrs. R. and J. Evans & Co., Liverpool, a steamer for the firm of Messrs. Wm. Thomas & Co., of Liverpool, for the India and American trade. The dimensions are:—280 ft. long, 35 ft. 8 in. breadth, and 24 ft. 7 in. depth of hold, with a gross register tonnage of about 2,200 tons, and to carry about 3,000 tons, and is built to the highest class in English Lloyd's. She will have engines constructed by Messrs. D. Rollo & Sons, Liverpool, of about 1,000-horse power effective, on the compound surface condensing principle. She was christened the *Empire* by Miss Roberts, daughter of Robert Roberts, Esq., of Trefriw.

Zenobia.—On September 24th a screw steamer was launched from the iron shipbuilding premises of Messrs. Thomas Turnbill & Son, Whitehall, Whitby. The vessel was christened the *Zenobia* by Mrs. Turner, wife of the principal of the firm of Messrs. Turner, Brightman, & Co., London, to whose order she has been constructed:—Length, 286 ft.; breadth, 36 ft.; depth of hold, 24 ft. Built under the three-deck rule to class 100 A 1 at Lloyd's. Engines, 160-horse power, by Blair & Co., fitted with water ballast, iron lower-masts, steam winches, and patent windlass by Emerson Walker & Co.

Androsa.—On September 24th, Messrs Oswald, Mordaunt, & Co., launched from their shipbuilding and engineering works at Southampton, an iron sailing ship of 2,000 tons register, named the *Androsa*, built to the order of Messrs. E. F., and W. Roberts, Liverpool, and of the following dimensions:—Length, 272 ft.; breadth, 40 ft.; depth of hold, 24 ft. The ship is built with full poop, monkey forecastle, and large midship-house for crew. She is intended to class 100 A 1 at Lloyd's; also to take the highest class in the Bureau Veritas, The ceremony of naming the vessel was performed by Mrs. Gilles, wife of the captain. When fitted out the vessel will be commanded by Captain Gilles.

Dorothy Watson.—On September 26th, there was launched from the Union Co-operative Shipbuilding Yard, Sunderland, a wood schooner of the following dimensions:—Length, 86 ft. 7 in.; breadth, 21 ft, 1 in.; and the depth of hold, 9 ft. 1 in. The vessel is 99 21-100th tons register, and is classed nine years at Lloyd's. She has been built to the order of Mr. Walter Herron, of Blyth, and is intended for the Baltic and coasting trades. The ceremony of christening the vessel the *Dorothy Watson* was performed by Miss Cameron.

Ossoro.—On October 1st, Messrs Scott & Co., Shipbuilders, Cartsdyke, launched a small screw steamer of about 180 tons, built to the order of the Pacific Steam Navigation Company. On leaving the ways she was named the *Ossoro.*

Hughenden.—On October 5th, Messrs. William Gray & Co., launched from their yard an iron screw steamer of the following dimensions:—268 ft. by 35 feet. 6 in., by 19 ft. 9 in, to the order of Mr. T. Hudson, of West Hartlepool, intended for the American and Indian trade, to carry 2,500 tons. She is fitted with all recent improvements, including steam steering-gear amidships and screw hand gear aft. Patent windlass by Emerson and Walker, and four steam-winches by Clark, Chapman, & Gurney, Gateshead. On leaving the ways the christening ceremony was performed by Mrs. Roe, of Staincliffe, Seaton Carew, the vessel being named the *Hughenden.* The engines, which are 200-horse power, are to be fitted by Messrs. Blair & Co. (Limited), of Stockton-on-Tees. This is the fourth vessel built by this firm for Mr. Hudson within three years, and two others are now in course of construction at the same yard for that gentleman, to be named respectively *Hawarden* and *Hatfield.*

Sues.—On October 6th, a screw steamer was launched from Messrs. Palmer & Co's yard at Jarrow, named the *Sues.* This vessel has been built to the order of MM. d'Orbigny, and Fausten Fils, of La Rouchelle, in France, She is 285 ft. long, 36 ft. beam, and 27 ft. depth of hold. She will be driven by engines of 180-horse power nominal, and will carry 2,900 tons. The fittings are all of the most modern and improved type. This vessel is for the Atlantic and general trades, and is fitted with Messrs. Emerson Walker & Co's patent windlass.

Wasdale.—The other day another launch took place from the yard of the Whitehaven Shipbuilding Company, Whitehaven. The vessel, which was christened the *Wasdale*, has been built to the order of Mr. J. D. Newton, of Liverpool, and she is the largest sailing ship that has been built on the Cumberland coast. Her length is 275 ft.; breadth, 39 ft.; depth of hold, 24 ft. 3 in.; and she is 1,800 tons register. She is classed A 1 at Lloyd's, and 20 years in red (Liverpool).

Jessomene. - On October 8th Messrs. W. H. Potter & Son launched from their shipbuilding and engineering works, Queen's Dock, Liverpool, an iron sailing ship, of the following dimensions:—Length, 270 ft.; breadth, 39 ft. 6 in.; depth of hold, 24 ft.; tonnage, B.M., 2,050 tons: tonnage nett register, 1,900 tons; deadweight capacity, 3,100 tons. The vessel was named the *Jessomene* by Miss Jessie Kerr Fernie. The ship has been built to the order of Messrs. Henry Fernie & Sons, of Liverpool, being the fourth vessel that Messrs. Potter have recently constructed for them. She is classed 100 A at Lloyd's, and 20 years in red in the Liverpool Underwriters' book. This vessel will be placed in the loading berth for Melbourne, and will be commanded by Captain Fisher, late of the ship *Pythomene.*

Hong Kong.—On October 8th was launched the *Hong Kong*, at the Neptune Works of Wigham Richardson & Co. on the Tyne. The owners are Wm. Milburn & Co. The christening was performed by Miss Atkins, of Leamington, Warwickshire.

Ixia.—On October 8th there was launched from the yard of the Tyne Iron Shipbuilding Company (Limited), of Willington Quay, on Tyne, an iron screw steamer of the following dimensions, viz.:—Length between perpendiculars, 287 ft.; breadth, 37 ft.; and depth, 23 ft. 6 in. The vessel has been built to the order of J. Robinson & Co., of North Shields, and is named the *Ixia.* Her engines are supplied by the North-Eastern Marine Engineering Company (Limited), of Sunderland, and are as follows:—Diameter of cylinders, 33 in. and 63 in.; length of stroke, 39 in. She is fitted with all modern appliances, including Tysack's patent anchor.

York City.—On October 10th Messrs. William Gray & Co., West Hartlepool, launched an iron steamship, to the order of Messrs. Thomas Furness & Co., of West Hartlepool, for their line between that port and New York. Her dimensions are:—Length, 280 ft.; breadth, 40 ft.; depth, 22 ft. 6 in.; carrying capacity, about 3,000 tons. The engines, of 250-horse power, will be supplied by Messrs. Blair & Co., of Stockton-on-Tees. She will be furnished with all the latest improvements, including steering-gear patent windlass, and water condensers capable of supplying 500 head of cattle and a large number of small stock, fittings for carrying which will be arranged on an entirely new plan, enabling the steamer to carry general cargo on her cattle decks when not occupied by live stock. On leaving the ways she was named the *York City* by Mrs. C. Furness, of Brantford House, West Hartlepool.

Zuid Holland.—On October 10th, Messrs. Raylton Dixon & Co. launched from their Cleveland Dockyard, Middlesbrough, an iron screw-steamer of 2,270 tons gross register, and 220-horse power nominal, for the Rotterdam Lloyd's Mail Line between Holland and Java. The dimensions of this vessel are :—Length, 311 ft.; breadth, 37 ft.; depth, 27 ft. She is classed 100 A 1 at Lloyds, and will be fitted with cabin accommodation for first-class passengers. She carries Messrs. Emerson Walker & Co.'s patent brass cone windlass. This vessel is the sixth which has been built for the same line by Messrs. Raylton Dixon & Co., and is a sister ship to the *Utrecht* (s.), also trading between Rotterdam and Java. On leaving the ways she was christened the *Zuid Holland* by Mrs. John Bell, of Rushton-hall.

Schaldis.—On October 11th there was launched from the yard of Messrs. C. S. Swan & Hunter, an iron screw-steamer, built to the order of the Société Anonyme Anversoise d'Armement et de Transports Maritimes, Antwerp, of the following dimensions:—Length between perpendiculars, 285 ft.; breadth extreme, 36 ft.; depth of hold, 24 ft. She is fitted with double bottom in after hold and engine-room, and a large deep tank in fore hold, to be also used for cargo; four steam winches, windlass by Emerson Walker, and will be fitted with engines 35 in. and 68 in. cylinder 45 in. stroke, built by the Wallsend Shipway and Engineering Company. As she left the ways she was named the *Schaldis* by Miss Minnie Hunter.

Tredegar.—On October 13th a screw-steamer, built to the order of Messrs. Mosel Brothers & Co., of Cardiff, was launched from the Willington Quay Yard of Messrs. Palmer & Co. She was named the *Tredegar*. Her length is 240 ft.; breadth of beam 33 ft.; depth, 18 ft. The *Tredegar* is a sister ship to the *Ebbw Vale*, belonging to the same firm, which was recently launched at the same yard. She is fitted with Emerson & Walker's patent windlass.

City of Hamburg.—On October 22nd there was launched from the building-yard of Mr. James Laing, Sunderland, a handsome screw-steamer, built to the order of Messrs. Palgrave, Murphy & Co., of Dublin and London, of the following dimensions:—Length, 240 ft.; breadth, 32 ft. 6 in.; depth, 16 ft. 3 in. She will be classed 100 A 1 at Lloyd's, and will have Board of Trade passenger certificate. She has splendid accommodation for passengers, her saloon being very spacious, and fitted with polished hardwood. She is fitted with double bottom to contain 250 tons water ballast, divided into four compartments; main deck of iron, and all the latest improvements suitable for the various Continental trades in which her owners are engaged. The vessel is fitted with Emerson & Walker's patent windlass, with Higginson's steam steering-gear, and will carry 1,450 tons, with a speed of 10 knots. Her engines, of 150-horse power, will be supplied by the eminent firm of Messrs. T. Richardson & Sons, Hartlepool, and are the tenth pair supplied by them to the same owners, besides two pairs in process of construction. The vessel has been built under the joint supervision of Captain Carnegie, the company's marine superintendent, and their senior captain, J. Walsh. The vessel, on leaving the ways, was gracefully named *City of Hamburg* by Miss Margaret Laing, daughter of the builder.

Lindus.—On October 24th Messrs. Edwd. Withy & Co. launched from Middleton Shipyard, West Hartlepool, an iron screw-steamer built to the order of Mr. Joseph Fawcett, of Newcastle-on-Tyne. Her principal dimensions are :—Length B. P., 257 ft. 6 in.; beam, extreme, 34 ft. 6 in.; depth, moulded, 20 ft. 4½ in. She has T. Y. forecastle, bridge-house, long quarter deck, and a short poop for the cabin; has double bottom all fore and aft for water-ballast constructed on the "cellular" system. The decks, chart-house, engine skylight, cabin companion and skylight are built of iron. She will be fitted with 4 patent steam winches and donkey boiler, and will be rigged as a double topsail schooner. She has been built under Lloyd's special survey for the 100 A 1 class, and will be fitted with engines of 150 nominal horse power by Messrs. J. Richardson & Sons, of Hartlepool Ironworks. On leaving the ways the steamer was christened *Lindus*.

Angola.—On October 12th Earl's Shipbuilding and Engineering Co. (Limited) launched from their yard at Hull a fine iron screw steamer, named the *Angola*, which is intended for the mail and passenger service between Lisbon and the Portuguese settlements on the west coast of Africa. This is sister vessel to the s.s. *Portugal*, which Earle's Co. completed recently for the Empresa Nacional, of Lisbon. She is 290 ft. p.p., 35 ft. beam, and 25 ft. 6 in. deep; is spar-decked; built to class 100 A 1 at Lloyd's; is about 2,000 tons gross; will be brig rigged; has provision for 400 tons water ballast, and accommodation for 60 first-class passengers and 30 second-class, as well as third-class passengers. She will be propelled by compound engines of 220 nominal horse power, having cylinders 40 and 72 in. diameter by 45 in. stroke, and two large boilers, the working pressure of which is 85 lbs.

Virginian.—The new and powerful iron screw-steamer *Virginian*, built for Messrs. Fred. Leyland & Co., of Liverpool, for their American trade between Liverpool and Boston, has been launched from the yard of the Palmer Ship-building and Iron Company (Limited), Jarrow. The *Virginian* is the longest iron steamer or vessel of any class that has been built on the East Coast, and when completed will be one of the finest, most powerful, and capacious cargo and passenger screws turned out on the Tyne or neighbouring rivers. Her dimensions are :—Length over all, 435 ft.; breadth, extreme, 41 ft.; and depth of hold, 29 ft. 6 in. She is built to the highest class of the Liverpool Underwriters Registry, at the same time the scantling is considerably in excess of the requirements of the Registry. The steamer has three decks, all fore and aft; the upper one being ⅝ in. in thickness, with edges double, and the butts treble rivetted fore and aft, and sheathed with pitch pine. Extra care has been taken to considerably add to the strength of the bottom by means of additional depth of floor plates, and by extra keelsons at the bottom, bilges, &c. The hull is divided into eight water-tight compartments by seven transverse bulkheads of great strength. She has a long turtle back forecastle in which is provided excellent accommodation for the crew; a long midship deck house furnishes admirable quarters for the first and second class passengers and officers; while a large house aft affords protection to the store house and wheel-house, containing Hainston's patent steam steering gear, which will be worked from the wheel-house amidships by means of steel rods and bevel gearing carried aft underneath the upper deck. The vessel is to be rigged with four iron pole masts, with heavy yards on the two foremost masts. There will be 16 winches on the upper deck, one to each hold; and Emerson & Walker's patent direct acting steam windlass on the forecastle. The upper and main decks will be fitted up to accommodate cattle, and the great length of the steamer will allow ample space for 700 head; while in the hold there will be room for the stowage of over 4,000 tons of general cargo. Special provision has been made to preserve the cargo from damage from dampness, &c., by having a double ceiling and permanent dunnage, the latter in the bottom being placed six inches clear above the ceiling. The engines are made on Allibon's patent four-cylinder principle, having two high-pressure cylinders, each 29 inches in diameter, and two low-pressure cylinders, each 60 in. in diameter, with a stroke of 60 in. The engines are capable of working up to over 3,000-horse power. The crank shaft is made up of six separate pieces bolted together, an arrangement patented by Mr. Turton, of Liverpool. The shaft is 16½ in. in diameter by 20 ft. long. The shells of the boilers are made of Siemens-Martin's steel, and are constructed to bear a working pressure of 90lbs. to the square inch. The arrangements for launching so long and heavy a structure were made with the utmost care, every precaution being taken to prevent accidents. By a novel and ingenious contrivance the dog shores were knocked out by four heavy weights falling upon them. The weights, connected with a rope winch, were lead to the front of a platform erected at the head of the vessel, and the launching was performed by cutting the rope which freed the weights and allowed them to knock out the dog shores. The interesting ceremony of launching the *Virginian* was performed in the presence of several thousands of spectators by Mrs. C. M. Palmer, and among those present were C. M. Palmer, Esq., M.P., and chairman of the Palmer Company, the Mayor of Jarrow (Mr. O. H. Duffell), &c. A beautiful ebony and silver mallet and handsome chisel (placed in rich case) was presented to Mrs. Palmer by Mr. John Price, the general manager, with which the lady in a graceful manner launched the fine steamer. As the *Virginian* glided down the ways and took the water, which she did in fine style, the spectators cheered most lustily. After the successful launch, a number of invited guests adjourned to the drawing offices of the builders, where a luncheon was served in good style. Mr. C. M. Palmer, Esq., M.P., occupied the chair, and in proposing "Success to the good ship *Virginian*," said that the vessel was an evidence of the progress they were making in the construction of their mercantile marine, she being the longest steamer ever built on the East Coast. He had no doubt if they continued to make the progress in the future they had in the past few years, that in the course of time they would see ships so increase in dimensions that the *Great Eastern* would no longer be the largest ship in the world. In the manner of providing accommodation and luxurious comfort for passengers he thought the owners of their large steam-liners have shown more progress and enterprise than the managers of railways. Such steamers as the *Virginian* showed that the builders on the East Coast could turn out the highest class of work; equal to the builders of any other district. (Hear, hear, and applause.) He concluded by wishing speedy voyages to the *Virginian*, and that life might never be lost out of her, and that the Messrs. Leyland might receive that profits out of her which their spirit and enterprise deserved. (Applause.)—Mr. John Price (vice-chairman) proposed in eulogistic terms the health of Mrs. Palmer, who had so successfully launched the *Virginian*. The toast was drank with enthusiasm. Mr. C. M. Palmer in responding, referred to the novel arrangement by which the vessel was launched, and highly commended Mr. Robert Armstrong, the ship-yard manager, and his foremen and workmen, for the anxious care they had bestowed on their work. So long as the men and foremen and managers continued to work in harmony as they did in the Jarrow yard, and performed their work honestly and conscientiously, he had no fear of French bounties injuring the mercantile marine of England.

Tancarville.—An important event took place on the Tyne at Scotswood on October 22nd, in the launch of the first ship built above the bridge. An extensive shipbuilding yard was opened at Scotswood, adjoining the Suspension Bridge, in February of this year, by Messrs. Campbell, MacIntosh, & Bowstead. At first only 100 men were employed, but the number of workmen increased to nearly 600, and the spacious yard was completely furnished in every department of construction. The keel of the first vessel was laid in the middle of April, and was built to the order of Mr. C. Brown, shipowner, of Havre, for the purpose of general trade. The vessel was constructed under the spar-decked rule, and its internal arrangements are such as will afford, with alteration, accommodation for cattle and provide for passengers. Amidships and under the bridge there is a saloon, and above the spar deck there is accommodation for the captain and officers. There is provision in the forecastle for the firemen and seamen. There are provisions for water ballast in the after hold, and also in the main hold. The dimensions of the steamer are:—Length, 293 ft.; breadth, 36 ft. 9 in.; depth of hold, 27 ft. 6 in.; and the vessel will carry 3,200 tons deadweight. She is classed 100 A 1 at Lloyd's and highest class "Veritas." She is schooner rigged, with double topsails, and is furnished with four steam winches by Messrs. Clarke, Chapman, & Gurney, Gateshead, and patent windlass by Messrs. Emerson, Walker, & Co., London. She is further provided with teak chart-house and iron wheel-house amidships over hurricane deck, with two lighthouses on the look-out bridge forward. The steam gearing amidships and aft and the iron wheel-house are by Messrs. Higginson & Co., Liverpool. In the forward part of the vessel there it an anchor crane. The engines are by Messrs. Thomas Clark & Co., Elswick, and are of 270 nominal and 1,350 effective horse power. The steamer was built under the superintendence of Messrs. Ashlin & Ashbridge, consulting engineers and naval architects, Liverpool. The Scotswood firm have three other vessels in course of construction—one for Messrs. Bowstead & Co., of London, for Eastern passenger trade; one for Mr. Lund, of London, for Australian passenger trade; and another for Messrs. Wm. Milburn & Co., Newcastle. Two of these vessels are of large dimensions, one of the same size as the steamer launched recently, and the other 290 ft. in length. Immediately after the launch another keel was laid for Messrs. Wm. Milburn & Co.; and the firm hold other orders for steamers of larger dimensions, and their construction will be pushed forward as soon as possible. The number of workmen is, as we have said, nearly 600, and the firm will soon employ other 200. One drawback is experienced in the deficiency of working-class houses in the neighbourhood, but this will be speedily overcome. Between Scotswood and Benwell there is a very large portion of land admirably adapted for workmen's dwellings, and we believe that buildings will be commenced, to supply a much-felt want. The launch of the *Tancarville*—so the vessel was named—attracted much attention, and was witnessed by hundreds of people gathered in the shipyard and crowded on one ot the iron vessels in course of construction, and on all parts of the deck of the new steamer. There were two steam-tugs and river police boats in attendance, and the shipyard and offices were decorated with flags. About three o'clock, the supports having been removed, the steamer moved down the slipyard amidst the cheers of the spectators, and the vessel received its name from Mrs. Campbell, the wife of one of the partners, as it glided away. After the launch the visitors assembled in the office, where the health of Mr. Brown, the owner, with success to the ship, and also the health of the builders, was drunk. Mr. Campbell occupied the chair.—Mr. Hedley said he had great pleasure in proposing the health of the firm of Messrs. Campbell, MacIntosh, and Bowstead, and in congratulating them very much on the very successful launch all had witnessed. (Cheers.) That was No. 1—the first ship they had built above bridge—and she was, as the visitors had seen, a very large one. He hoped it was the commencement of a very successful business in that yard; and his wish was that the three partners might have health and strength to conduct in the way they had begun the business they had commenced there. (Cheers.)—Mr. Bowstead said he had to thank them on behalf of his partners and himself for the very kind manner in which they had drunk the health of the members of the firm. The greatest pleasure they had felt that way had been not merely the success of the launch, but the very kind wishes which had been expressed by so many of their kind friends and neighbours on that occasion. (Applause.)

County of Pembroke.—On October 22nd, there was launched from the shipbuilding yard of Messrs. William Doxford & Sons, Sunderland, for Messrs. William Thomas & Co., Liverpool, a sailing vessel of the following dimensions:—221 ft. long; 35 ft. breadth; and 21 ft. depth of hold; and of about 1,700 tons burthen, and of the highest class at Lloyd's. She was christened the *County of Pembroke*, by Mrs. Williams, wife of Captain Williams, who will command the ship.

Chittagong.—On October 24th, the *Chittagong (s)* was launched from the yard of Messrs. Raylton, Dixon, & Co., for Messrs. Patrick Henderson, & Co., of Glasgow, for their Rangoon trade. The ship is of the following dimensions:—Length, 285 ft.; breadth, 36 ft. 3 in.; depth, 23 ft. 3 in., and her carrying capacity about 2,200 tons, having engines of 180 h.p. by Messrs. Blair & Co. She has water ballast throughout on cellular principle, iron main and upper deck covered with teak, cabins in poop aft, long close bridge, and topgallant-forecastle, and, being built principally for the Rangoon trade, is fitted with special arrangements for loading, ventilating, and discharging. She has Harfield's patent steam windlass, and Bow and M'Lachlan's steam steering gear. Captain M'Kirdy, late of the British Indian Service, will command her, and his wife performed the christening ceremony.

Cordelia.—On October 25th, the *Cordelia* was successfully launched at Portsmouth. The christening ceremony was performed by the Hon. Mrs. Foley, wife of Admiral Foley, the Dockyard Superintendent. The *Cordelia* is in all respects a sister ship to the *Canada*, which was launched from the adjoining slip a month ago, and christened by the Crown Princess of Germany, and to the *Calliope*, the construction of which has just been commenced at Portsmouth. Her dimensions are 225 ft. in length between perpendiculars; 44 ft. 6 in., extreme breadth, and 21 ft. 6 in., depth of hold; while her load displacement is 2,383 tons. She will have a mean draught of 17 ft. 9 in., and will carry, instead of the present *Comus* armament of 14 guns, 10 guns of the new 6-inch breechloading type. She will be provided by Messrs. Rennie with a pair of horizontal compound engines, working up to 2,300 horses, and which are expected to realize a speed of 13 knots an hour, with 100 revolutions a minute.

LAUNCHES.—SCOTCH.

Thames.—On September 26th, there was launched from the yard of Messrs. James and George Thompson, at Clyde Bank, Glasgow, a screw-steamship of 4,200 tons and 5,000-horse power, for the Peninsular and Oriental Steam Navigation Company. The name of *Thames* was conferred by Mrs. George P. Thomson. The *Thames* will get her engines and boilers from Clyde Bank Foundry, and she will return to dock at Clyde Bank to be equipped and completed. She is 390 ft. long; 42 ft. broad; and 35 ft. deep; with engines of 750-horse power nominal. The vessel will accommodate 120 first-class and 48 second-class passengers, and will carry over 3,000 tons of cargo. The first voyage of the *Thames* will be on the Company's Australian line.

Antilles.—On September 26th, Messrs. Napier, Shanks & Bell, Yoker and Glasgow, launched a screw-steamer 270 ft. by 33 ft. 6 in.; and 19 ft. 3 in.; about 1,350 tons, built for Messrs. Scrutton, Sons & Co., of London, as an addition to the Direct West India Line. The *Antilles*, as the new vessel is named, has been constructed to Lloyd's highest class, with double bottom on the continuous girder system, and combines the most approved arrangements and appliances for the West India trade. Superior accommodation is also provided for a number of first-class passengers in a well-ventilated poop. The engines. 34 in. and 58 in. diameter, 36 in. stroke, are supplied by Messrs. James Howden & Co., Glasgow. At the launch the owners were represented by Thomas Scrutton Esq., David Caw, Esq., and Captain Ball. The naming ceremony was performed by Miss Campbell, of Bradford.

Cape Clear.—On September 30th, Messrs. Steele & Co., Shipbuilders, Greenock, launched an iron screw-steamer, built to the order of Messrs. A. Lyle & Sons, and intended for the Java sugar trade. She is a vessel of 2,200 tons, with engines of 200-horse power, and measured 290 ft. in length; 30 ft. in breadth; and 28 ft. in depth. It is understood that she is the first of a line of steamers proposed to be built by Messrs. Lyle, in addition to their magnificent fleet of sailing vessels. She was named the *Cape Clear* by Miss Lyle.

Professor.—On October 8th, Messrs. Scott & Co., Cartsdyke, Greenock, launched a screw steamer of 2,550 tons gross, which, as she left the ways, was named the *Professor* by Mrs. Alex. Gauld, wife of Mr. Gauld, of the Commercial Bank. The dimensions of the new vessel are:—Length, 350 ft.; depth, 28 ft.; and breadth, 37 ft. Her engines of 350-horse power, are to be supplied by the builders. She is fitted with a patent direct steam windlass by Emerson, Walker & Co., London. The *Professor* has been built to the order of Messrs. F. and J. Harrison, Liverpool.

Clydesdale.—On October 8th, Messrs. Blackwood & Gordon launched from their yard at Greenock a screw-steamer of 1,300 tons and 240 ft. long named the *Clydesdale*. This is the third new steamer built for the "Dale" Line, managed by Messrs. R. M'Kill & Co., Glasgow, and engaged in the Mediterranean trade. The *Clydesdale* is fitted with engines of 120-horse power by her builders.

Fooksang.—On October 8th there was launched from the building-yard of Messrs. Hall, Russell & Co. an iron screw steamer, named *Fooksang*, of the following dimensions:—Length, 255 ft.; breadth, 35 ft. 6 in.; depth 23 ft.; and 1,580 tons gross. This vessel has been built under special survey to class 100 A at Lloyd's, and will be fitted with compound surface condensing engines of 180 horse power nominal, steam winches, steam steering gear, patent steam windlass, water ballast, and all the most approved appliances for facilitating the loading and discharging of cargoes. The *Fooksang* has been built to the order of Messrs. Mathieson & Co., of London and China, and is specially fitted for the China trade, having large ports in 'tween decks for light and ventilation, with a light shade or sun deck extending the whole length of the vessel. As the vessel left the ways the ceremony of naming was performed by Miss M'Bain, daughter of the superintendent.

Nerbudda.—On October 10th Messrs. Russell & Co., Shipbuilders, Greenock, launched from their shipbuilding yard an iron ship of 1,550 tons nett, and of the following dimensions:—Length, 258 ft.; breadth, 38 ft.; and depth 22 ft. 9 in. The vessel, which has been built to the order of Messrs. Foley, Aikman & Co., Shipowners, London, is intended for the East India trade, and has been fitted up with all modern improvements for the rapid loading and discharging of cargo. On leaving the ways she was named the *Nerbudda*. After the launch the vessel was towed to Port Glasgow, where she will be masted and fitted out for sea.

John Ray.—On October 12th a steamer was launched by Mr. W. B. Thompson, from the Caledon Yard, Dundee. The vessel, which was named the *John Ray*, has been built for Messrs. M. A. Ray & Sons, of London. Her dimensions are—106 ft. long, 36 ft. broad, and 14 ft. deep, and the class is 100 A1 at Lloyd's. The vessel will be fitted with topgallant forecastle, bridge-house, and break poop, and will be provided with compound engines of 85-horse power nominal. The latest improvements have been introduced, such as water ballast tanks, steam-winches, steam-gearing, &c. The steamer is intended for the coal trade between London and the north of England, and is about 500 tons burthen.

Ardangorm.—On October 13th there was launched at Messrs. Ramage & Ferguson's ship-building yard, Leith, an iron screw steamer named the *Ardangorm*, 1,600 tons gross, and 2,150 tons deadweight capacity, for Messrs. M'Laren, Crum & Co., Glasgow. This vessel has been specially designed for the Mediterranean and East Indian trade, and has all the latest improvements, including steam-windlass, steam-winches, water ballast, teak deck, &c. Her dimensions are 260 by 35 by 19 ft. hold; and engines of 200-horse power nominal being supplied by Messrs. Walker, Henderson & Co., of Glasgow.

Harlaw.—On October 14th Messrs. Cunliffe & Dunlop launched from their engineering and shipbuilding works at Port Glasgow an iron screw steamer of 500 tons burthen, and 80 h.-p. nominal. Her dimensions are as follows:—165 ft. between perpendiculars; 24½ ft. beam; and 13½ ft. depth of hold. As the vessel left the ways she was named the *Harlaw* by Miss Dunlop, of Glasgow, and was immediately thereafter laid under the crane at the builders' wharf, where she will receive her machinery, which is also being constructed at Inch Works. The *Harlaw* has been built to the order of the Aberdeen Steam Navigation Company, and is intended for their cargo trade between Aberdeen and London, being fitted with all the latest applications for working. Her fittings include Muir & Caldwell's steam cranes and steering gear, and also M'Onie's steam windlass. Like the other steamers of this company the *Harlaw* is built to attain a high rate of speed.

Chi Yuen.—On October 17th there was launched from the building yard of Messrs. Lobnitz & Co., Renfrew, a screw steamer of the following dimensions:—285 by 34.1 by 24.6. As she left the ways she was named the *Chi Yuen*, by Mrs. Thomas Weir, of Shanghae. Immediately after the launch the vessel was taken into the builders' tidal dock, where she will receive her machinery. The *Chi Yuen* is the property of the China Merchants' Steam Navigation Company of Shanghae.

Illawarra.—On October 22nd, Messrs. Dobie & Co., launched from the Govan Shipbuilding Yard and iron sailing ship, built to the highest class, to the order of Messrs. Devitt and Moore, of London, for the Australian trade, and measuring fully 2,000 tons gross. As she left the ways, she was named *Illawarra* by Mrs. Carvosso, the wife of Captain D. B. Carvosso, well known in the Australian trade, who is in command.

Hermes.—On October 22nd, Messrs. Robert Duncan & Co., Port Glasgow, launched an iron sailing ship named *Hermes*, built to the order of Mr. R. R. Paterson, Greenock. The following are her dimensions:—235 by 37 by 21·6; about 1,600 tons. She is classed 100 A 1 at Lloyd's, and is intended for the East India trade.

Glenfarg.—On October 24th, there was launched from the shipbuilding yard of Messrs. Alex. Stephens & Sons, of Dundee, an iron barque, named the *Glenfarg*, to the order of Messrs. W. O. Taylor & Co., of Dundee. The *Glenfarg* is about 900 tons register, intended for the West Coast trade, and will be commanded by Captain John M'Glashan. A sister ship, to be named the *Glenshee*, is being built by Messrs. Stephen, for the same owners.

LAUNCHES.—IRISH.

Skelligs.—On September 22nd the ninth steamer, built by Messrs. Workman, Clark, & Co., was successfully launched from their recently-erected premises, Spencer Basin. This latest addition to our mercantile navy has been built to the order of the Clyde Shipping Company, and we understand that she is intended for the West of Ireland coasting trade, having special accommodation on the main deck for the transit of live stock. Her dimensions give her a gross tonnage of 500; length being 160 ft.; breadth of beam 25 ft. 6 in.; and depth of hold 12 ft. The rig is that of a fore and aft schooner, and like all Messrs. Workman, Clark, and Co.'s vessels, has been built under special survey to class 100 A 1 at Lloyd's. A raised quarter deck and top-gallant forecastle are among the leading features. In her build—and in this, as indeed in every detail of her construction—the greatest available skill and most improved methods have contributed to make her as perfect as possible. Messrs. Rowen & Sons, Limited, have had the order for the engineering requirements of the new vessel, and are about to supply her with the pair of compound, inverted, direct-acting, impact, condensing engines of about 100 horse-power, the cylinders being 20 and 42 in. diameter and 36 stroke, as well as a pair of steam-winches, and with brass cone brake windlass, Emmerson, Walker & Co.'s patent. In connection with the latter it may be mentioned that in the building and fitting out of this vessel, particular attention has been directed to the system of loading and unloading with the view to the adoption of one that would secure the maximum of both expedition and safety, and it is believed that in the arrangement now followed it will prove to be satisfactory in its working. The launch was witnessed by a number of friends of the firm, and as the ship glided from the slip she was gracefully christened the *Skelligs* in the usual orthodox fashion by Miss Pinkerton. Shortly afterwards the *Skelligs* was towed into Prince's Dock, where the engines and fittings will be put in their place. There are at present four other steamers on the stocks of this yard, one of them built to the order of the City Line of Glasgow, being over 4,000 tons, and measuring 400 ft. long, and the total tonnage of the quartette reaching over 7,300. This is a pleasing index to the activity of the trade in Belfast, and we are equally glad to know that the other large establishments are in a similar satisfactory state at the present time.

Shannon.—On October 6th a steel-built vessel was launched from the yard of Messrs. Harland and Wolff, Belfast. This new vessel has been built to the order of the Peninsular and Oriental Steam Navigation Company, and is intended for the Australian passenger trade. Her dimensions are:—Length, 450 ft.; breadth 42 ft. 6 in.; gross tonnage, 4,300. She is classed 100 A at Lloyd's, and her engines will be over 4,000-horse power. The christening ceremony was performed by Mrs. Kellock, the wife of the superintendent of the company, the vessel receiving the name of the *Shannon* as she glided from the slip.

LAUNCH.—FRENCH.

La Ville de Montévidéo.—On September 18th was launched from the shipbuilding-yard of Forges à Chantiers de la Méditerranée, at La Teyne, near Toulon, an iron screw steamer, built for the Compagnie des Chargeurs réunis du Hâvre. The dimensions are:—Length between perpendiculars, 294 ft.; breadth moulded, 35 ft.; depth moulded, 25 ft.; tonnage, net registered, 1,400 tons: She will carry about 3,000 tons, and is classed at the highest class of Bureau Veritas under special survey. She will be provided with direct-acting compound engines of 1,000 indicated horse-power by the same firm at Hâvre. Cylinders 34 and 64, with 40 in. stroke. Steam will be supplied from two large cylindrical boilers, with large heating surface and of superior construction for a working pressure of 80 lbs. The steamer is to be brig-rigged and spar-decked. She will be fitted with double bottom for water ballast, four steam-winches, and all the most recent and improved appliances for expeditious loading and discharging cargoes, patent windlass and patent steam-steering gear. In addition to superior cargo space for the conveyance of general goods, the vessel will be able to accommodate, in 'tween decks, 460 emigrants. A great improvement has been made in regard to those accommodations; a special feature in this vessel is that the berths are arranged in single instead of double tiers, each tier being separated from the next by a passage with large sidelight at the end. This adds greatly to the ventilation, light, and comfort of the passengers. The captain and officers are accommodated in houses amidships and aft. The steamer was christened *La Ville de Montévidéo* as she left the ways. She will form the third of a fleet of fine screw steamers ordered by the same firm at Hâvre.

LAUNCH.—GERMAN.

Wandrahm.—On September 28th there was launched from the yard of the Flensburg Iron Shipbuilding Company, in Flensburg, a screw-steamer of the following principal dimensions:—Length between perpendiculars, 258 ft.; extreme breadth, 34 ft.; depth of hold, 24 ft. 9 in. The vessel is spar-decked and classed in the highest class of Bureau Veritas, and she is built for the Hansa Steam Navigation Company in Hamburg. On leaving the ways she was named *Wandrahm* by Miss Catherine Jurgensen, and was afterwards taken to the sheer legs to get in her engines (160-horse power), which are also built by the Flensburg Shipbuilding Company.

LAUNCHES.—SWEDISH.

Bordeaux.—On October 21st there was launched from the Motala Company's yard at Lindholmen, near Gothenburg, a steel screw-steamer of the following dimensions:—Length over all, 203 ft.; breadth moulded, 29 ft. 6 in.; depth of hold, 23 ft. 2 in.; and with a carrying capacity of 1,000 tons deadweight. This steamer is built of Motala Bessemer steel for the Svenska Lloyd's Company, at Gothenburg, for their Mediterranean service, will be classed at Bureau Veritas, and has been designed specially for cargo with spar deck, the main deck being of iron. She was named the *Bordeaux*, and will immediately receive her engines of 110 nominal horse-power.

Kalmuck.—There was launched from the Motala Company's yard at Norrköping, in September last, a paddle river steamer named *Kalmuck*. This steamer is built for the river Wolgan, in Russia, and her dimensions are as follows:—Length, 263 ft.; breadth moulded, 28 ft. 6 in.; depth of hold, 8ft. 6 in. The machinery, of 80 nominal horse-power, is placed at the after end of the ship. A sister boat to the *Kalmuck*, the *Tartar*, left the yard a month ago.

TRIAL TRIPS.

Cilurnum.—On October 1, the trial trip took place of the *Cilurnum* (s), built by Messrs. C. S. Swan & Hunter, Wallsend, for Messrs, Elliott, Lowry, & Dunford, Newcastle, the day being fine and the trial proved highly satisfactory. The dimensions of the *Cilurnum* are 225 ft. by 36 ft., by 24 ft. 6 in. The engines are by Messrs. R. & W. Hawthorn, 34½ in. and 64 in. diameter, by 42 in. stroke, and the vessel attained an average speed of 11·63 knots at the measured mile.

Claymore.—On October 1, the new screw steamer *Claymore*, recently built by Messrs. James & George Thompson, for the Clyde and West Highland tourist traffic, went down the Firth to go through her official speed trials. The guaranteed speed of the *Claymore* was to be 13¾ knots, but on the measured mile on Saturday the mean speed attained was 14¾ knots, or one knot in excess.

Chancellor.—On October 5th the *Chancellor* (s), built by Messrs. Raylton Dixon & Co., of the Cleveland Dockyard, Middlesborough to the order of Messrs. Edward Harris & Co., Middlesborough, took her trial trip. She is of the following dimensions:—Length, 279 ft.; breadth 37 ft. 3 in., and depth of hold 24 ft. 6 in., with a carrying capacity of about 3,000 tons deadweight. She is built on the three-decked principle, having two decks laid, the main one of iron and the upper of wood. She has also water ballast in a double bottom in the after main and fore-holds, four steam winches patent steam steering-gear, &c., iron lower masts, and is schooner-rigged. Her cabins for captain and spare state rooms are placed in a short poop aft, and the accommodation for officers and engineers, under the bridge amidships. Her engines, of 180-horse power, are by Messrs. Thomas Richardson & Sons, Hartlepool, and during the trial gave every satisfaction, and Patent Windlass by Emerson Walker & Co., London.

Brunette.—On October 10th the trial trip took place of the *Brunette* (s), built for Th. Rodenacker, Esq., Dantzic, by Messrs, C. S. Swan & Hunter, Wallsend. Length, 202; breadth, 28½; depth 15½; with engines by Messrs. Black, Hawthorn, & Co., Gateshead. The vessel attained a satisfactory speed, and returned to Tyne Dock to load a general cargo.

Banner.—On October 10th the *Banner*, an iron screw steamer, about 300 tons B.M. ran her official trial trip on the Clyde, attaining a speed of fully 10 knots loaded. She has been built at Paisley for James R. Currie, Esq., by Messrs. John Fullerton & Co., and is intended for the coasting and Channel trade. Her engines are by Messrs. Scott Brothers.

Mounts Bay.—On October 10th, the spar-decked screw-steamer *Mounts Bay*, which was launched by Messrs. Schlesinger, Davis & Co., at Wallsend, about a month ago, had a trial trip. On getting out to sea the steamer's head was turned to the north, and after the engines had got into thorough working order, she was run nearly as far as Coquet Island, when she was turned and brought at full speed back to the Tyne Dock, without any hitch in the working of the machinery. The leading measurements of the vessel are as follows:—Length between perpendiculars, 290 ft.; breadth moulded, 37 ft.; depth of hold, 27 ft. 3 in. The engines for this vessel have been built by Messrs. Black, Hawthorn & Co., of Gateshead, and have cylinders 37 in. and 70 in. diameter, with a stroke of 45 in. Although something approaching a gale of wind was blowing, and the vessel so light in the water that her propeller was not much more than half immersed, an average speed of 10½ knots per hour was obtained, which was highly satisfactory under such unfavourable circumstances.

Wydale (s. s.)—On October 17th, this new steamer proceeded to sea from the Tyne, accompanied by a large party of gentlemen, and after a most successful trial trip returned in the evening to Pelaw, where she will load for Genoa. Her dimensions are—275 ft. by 36 by 23. She is three-decked, and has a central iron bulkhead running fore and aft in the holds. The main deck is of iron, with extra strengthening so as to suit her especially for the Atlantic and other ocean trades. Her cabin arrangements are extremely convenient, and reflect great credit upon the builders. She is fitted with Messrs. Brown and Harfield's steam windlass, and all other recent improvements. Her engines, which are 190 horse-power, were found sufficient to propel the ship easy at 11 knots, although the propeller was only partially immersed. During the trial, the ship was steered by Simey's direct-acting steam-steering-gear, the only noticeable features about which appeared to be its handiness and silence in working. The ship has been built to the order of Messrs. Pantland, Hick & Co., of Scarborough, who fully appreciate Messrs. Readhead's capabilities, both as ship and engine builders.

Ville de Brugie.—This small coasting steamer, built by Forrestt of London, to the order of A. Rickard, Esq., ran a satisfactory trial trip on the Thames, attaining the speed of 8¾ knots. She is built entirely of steel, having hold for cargo forward of the machinery, which consists of a pair of 8 ft. surface condensing engines, return tube, boiler, &c. Passenger accommodation is fitted aft, and there is the usual forecastle arrangement, &c. The vessel is yawl rigged, and sails for Algiers this week.

La Ville de Rosario.—This screw steamer, lately launched at La Teyne built by the Forges à Chantiers de la Méditerranée, proceeded to sea to make her trial trip on September 15th. The dimensions are 294 ft. by 35 ft. by 25 ft. The average speed of 12·50 was obtained on the measured mile instead of 11·50 stipulated by contract. The next day a trial of twelve hours' running was made to ascertain the consumption of fuel, and the result showed a rate of 1·70 lbs. per indicated horse-power, the engines indicating 1,150 horse-power, number of revolutions, 65. The result was very satisfactory to every one connected with the construction or with the ownership of the steamer, and the engines worked during the whole trip with perfect smoothness. The *Ville de Rosario* immediately left La Teyne and proceeded to Hâvre, where she will load for South America.

Terge Viken.—The trial trip of this steamer, which was launched a few weeks ago from the Motala Company's yard ot Lindholmen, near Gothenburg, to the order of Consul Peterson, of Moss, Norway, took place on the 8th inst. under very favourable circumstances. The *Terge Viken* left the next morning for Königsberg, which port was reached in 50 hours. In length the *Terge Viken* is 159 ft.; breadth moulded 24 ft. 10 in; depth of hold, 15 ft. 6in. She is built to class at London Lloyd's, with raised quarter-deck, and will carry 600 tons deadweight. The engines are on the compound surface-condensing principle, of 50 nominal horse-power, and will give the speed of eight knots on load line.

Brahma.—On October 15th the twin screw steel steamer *Brahma* left the yard at Lindholmen, near Gothenberg, where she has been built, for a trial trip in the bay. This steamer, which is built for a company in St. Petersburg for their petroleum trade between Baku and Astrakan across the Caspian Sea, is of the following dimensions:—Length over all, 252 ft.; breadth moulded, 28 ft. 6 in. The machinery, of 120 nominal horse-power, worked very satisfactorily, the speed attained was little more than 10 knots, with a boiler pressure of 64 pounds per square inch. The material in hull and boilers is of steel from the Motala Company's own Bessemer works. This is the fifth steamer for the Baku petroleum trade built at Lindholmen, and which have to be taken in two separate piecesa through the Marine Canal to Wolgan.

Reviews.

Iron Founding.—By Claude Wylie: Published by Thos. Reed & Co., Sunderland.

This is a practical book by a practical man, and has been much wanted in manufacturing circles. The moulder and founder learn their trade by years of constant observance and practice, but they will do well to learn and analyze, and reason upon the processes they are in the habit of conducting, so as to be ready in meeting unusual conditions, or in rectifying unexpected results. The student in mechanical engineering has hitherto been very much at a loss for such information as is contained in this text-book, and will obtain a great deal of valuable information from it. The subject matter deals with all varieties of compositions of moulding sands and loam, much of the information therein contained being likely to prove of great value even to manufacturers and founders themselves. The precautions to be observed in running metal into the moulds in order to ensure sound castings are amply dilated on and explained. The composition of the iron suitable for producing a definite quality of casting is duly set forth, and excellent information is given as to the management of the cupola and fans or blowers. That valuable material, malleable cast iron, is also treated of, about which not much information can be obtained elsewhere, and, altogether, there is no department of founding in which the details are not clearly and plainly described.

British Wild Flowers.—By Frederick A. Messer: Published by David Bogue, of Trafalgar-square.

Botany is a subject that is most difficult to be acquired, from the enormous variety of orders and families that have to be classified and retained in the memory. The eye should be a great assistance to the memory in recalling the arrangements and classifications of such orders, if they are presented in a clear and graphic table. This object Mr. Messer may be certainly said to have attained by his very graphic tabulation of the distinctive characteristics of the different orders in distinct columns of shrub, calyx, petals, fruit, and leaves.

Correspondence.

[*It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.*—Ed.]

To the Editor of The Marine Engineer.

Sir,—Your correspondent "Wave" in your September part does not seem to be aware there is a Sea-Going Engineers' Association, but I have not noticed any improvement due to it much, as the craft needs to be improved. They have lately taken unto themselves a solicitor; he may exchange some of his ideas for theirs as they seem to be men of very few ideas,

Yours,

Sunderland, October 12th, 1881. Landsman.

To the Editor of The Marine Engineer.

Sir,—"Young Third" may find the pitch of his propeller in the following manner:—Take a piece of half-inch board, and shape it so that it is a right-angled triangle, the hypothenuse of which is the widest part of propeller blade. If the propeller is a true screw the hypothenuse will be a straight line, but if of increasing pitch will be slightly curved, and the board must be made to fit this curve. Get whole circumference of propeller and say—As perpendicular of triangle is to whole circumference, so is base of triangle to whole pitch.

Yours,

Sunderland, October 10th, 1881. Wave.

To the Editor of The Marine Engineer.

Sir,—In your impression of October 1st, you state in your "Editorial Notes" in reference to the improvements in the Navy, that "greater inducements is to be offered to young engineers of good education who have served a practical apprenticeship with private firms." Now it seems that engineers for H.M. Navy are not admitted after 16 years of age, and must undergo a course of instruction in a Naval Dockyard, and that is the only way of gaining admission, so I am informed by the secretary of the Admiralty about a fortnight ago. I always understood that if you passed the necessary examinations you would be admitted. As I am serving my time in a private firm on the Clyde, and have been undergoing a course of instruction which I thought would be the means of me joining the navy.

Perhaps you would be so kind as to enlighten me a little on the subject, and I shall feel very grateful, as I am undecided how to act.

I am, Sir, your obedient servant,

D. L.

Glasgow, October 21st, 1881.

[Your information is quite correct as to the present regulations. It is to remedy this apparent injustice to pupils of private firms that the extension of admission to H.M. Navy by examination, is now under the consideration of the Admiralty.—Ed.]

ANTI-CORROSIVE AND ANTI-FOULING COMPOSITION.

To the Editor of The Marine Engineer.

Sir,—I have read the letters of "Ex-Naval Officer" and "Ex-Mail Boat Officer," on "Anti-Corrosive and Anti-Fouling Compositions" for iron ships' bottoms in your last number with a good deal of interest, as they were evidently written by men practically versed in the subject.

Being myself an old mariner, and now largely interested, in a pecuniary point of view as a ship-owner, in this all important question to ship-owners, I shall be glad if the subject obtains a thorough investigation in your valuable pages, for the benefit of those of your readers, who like myself, "want their money invested in good bottoms."

I fully endorse all that "Ex-Naval Officer" says of the slovenly manner in which, as a rule, the work of coating the bottoms of ships, is done by the dry dock people, whose aim, it would appear to be, is to get the paint *on* and *off* again as quickly as possible.

The firm of which I am a member appear to have no difficulty in the matter, due, I suppose to the strict instructions they give their superintendent, to have the work well done, and to see that ample time be allowed for the priming or anti-corrosive coats to dry before the application of the finishing or anti-fouling coating.

The vessels maintain their high rate of speed very uniformly on their voyages out and home, and their bottoms are clean and in good order when they return, but, above all, the iron plate sappear to be thoroughly well preserved from rust or scale.

The compositions used are very excellent in their anti-corrosive and anti-fouling properties, and they are also very durable.

I do not suppose that these compositions are very widely known, or most certainly there would be less complaint amongst ship-owners of the foul state of their ships on their return home after a long voyage. I trust, however, their merit will gain for the manufacturers the reward they desire and deserve.

I may perhaps be doing good to my neighbours if I describe the *modus operandi* adopted with our ships.

Starting with a new ship, care is taken that every particle of scale in the iron is removed from the plates, *by hammering, not scraping*. Several coats of the anti-corrosive paints, as mentioned above, are then applied one upon the other, each coating being allowed to dry hard before the application of the next. By these means no oxydation of the iron can possibly take place. The anti-fouling coating is finally applied, which does not dry hard, but remains tacky on the surface, I am informed, purposely so compounded in order to prevent the adhesion of barnacles to weed.

The next time the ship is docked she is scrubbed down—scrapers are generally not necessary, or, if used at all, care is taken that the foundation paints are not disturbed. Should they, however, have been rubbed off from any cause, the bad places are made good with the anti-corrosive composition until the surface of the ships' bottom is uniformly good again. The bottom is then done all over with one or two good coatings of the anti-corrosive and finished with the anti-fouling composition. After a time the bottom becomes thickly coated with a good preservative compound and no trouble is experienced so long as the use of scrapers is ignored, and ordinary care is taken when fresh applications of the compositions are required.

I am, Sir, Yours faithfully,
OLD SALT.

To the Editor of THE MARINE ENGINEER.

SIR,—Would you kindly insert this in your November number,
And oblige,
JAMES KEMP,
Chief Engineer, s.s. *Gordon Castle.*

Port Said, Sept. 30th, 1881.

Gordon Castle.—The Castle Line of Tea Steamers, s.s. *Gordon Castle* of a gross tonnage of 2,020 tons, having had new boilers, engines overhauled, and ship re-classed, sailed from Royal Albert Dock, London, September 18th, 1881. Mean draught of 20 ft. 6 in. encountered a heavy "gale" in the Bay of Biscay for two days, still averaged over 11 knots to Port Said; from Gibraltar to Port Said with fair steaming averaged nearly 12 knots per hour. Loaded with tea she ought to maintain a speed of 12 knots. Although pioneer, and smallest of Messrs. T. Skinner & Co.'s line of "tea clippers" to and from China, will be one of the fastest of their fleet.

4154 J. G. Thomson (communicated by W. J. F. Thomson) Valves.

4155 Construction and propulsion of vessels.

4156 A. Longsdon (communicated by A. Krupp). Floating batteries.

4157 F. H. & F. A. Hamilton. Deck lights.

4178 C. C. Abel (communicated by A. Estrade). Steam superheating apparatus.

4180 C. W. King. Steam boilers, fireplaces, and combustion chambers.

4189 E. Latham. Steam-winches.

4190 H. S. Swift. Steam-engines.

4192 J. H. Johnson (communicated by P. Archer). Ventilating ships.

4198 W. R. Lake (communicated by H. Reusch). Armour plates.

4210 S. Pitt (communicated by R. P. Pictet). Construction of boats and vessels.

4211 R. H. Brandon (communicated by Gatling Gun Co.) Marine gun cartridge feeder.

4236 H. J. Haddan (communicated by I. F. Baudet). Boiler incrustation preventive.

4253 J. McMillan. Feeding fuel.

4262 R. Verdin. Appliances on flats for transhipping salt or coal.

4263 G. Wainwright. Steam boiler dampers.

4265 P. G. B. Westmacott. Rotary valves.

4270 E. A. Brydges (communicated by G. Gregersen). Pneumatic construction of pier foundations.

4274 J. A. Timmis Stowing and lowering ships boats.

4275 J. L. Rastrick. Steam boilers.

4276 C. Pieper (communicated by A. Knaudt). Steam boilers

4278 H. Goatley. Sliding seats for rowing boats.

4295 H. E. Newton (communicated by J. Ericsson). Steam engines.

4321 J. Jones. Screw-propellers.

4335 W. R. Kinipple. Construction of submerged structure.

4337 W. R. Kinipple. Propulsion of vessels.

4345 J. Rigg. Transhipment of coal, salt, corn, &c.

4347 J. Shepherd. Smoke consuming fire-box.

4354 J. Carr. Screw propellers.

4359 D. Young. Rotating shaft speed indicator.

4416 F. Hudson. Steam generator furnaces.

4427 E. G. Manbey. Pipe joints.

4440 A. Budenberg (communicated by C. F. Budenberg & B. A. Schaeffer). Indicators.

4451 P. Brotherhood. Discharging torpedoes under water.

4476 A. Simey. Boat detaching gear.

4485 G. Stevenson. Steam boilers.

4510 P. Turner. Governors.

4517 M. Hedicke (communicated by H. Gravel). Propelling vessels.

4523 J. Gallic. Lubricators.

4529 F. H. T. Engel (communicated by J. Eggers). Automatic revolution indicator.

4537 S. Hallam & J. W. Shepherd. Feed water apparatus.
4545 G. Hill. Steam boilers.
4546 E. Crompton & J. S. Cochran. Steam boilers.
4547 E. Crompton & J. S. Cochran. Water-tight sliding bulk head doors.
4550 R. Mills. Steam generators.
4560 S. Fox. Steam boilers.
4573 W. R. Lake (communicated by A. Holmes). Life boats and oars.
4580 J. Schwartz. Sounding apparatus.
4582 A. M. Clark (communicated by J. de Chanzy). Supply of electricity for lighting on steam boats, &c.

⁂ Any information regarding these or other patents will be gladly furnished on application.

BOARD OF TRADE EXAMINATIONS.

Return of Engineers reported to have passed examination under the provisions of the Merchant Shipping Act, 1854, during the month.

NOTE.—E 1 C denotes Extra First Class; 1 C, First Class 2 C, Second Class.

September 24th, 1881.

ROBERT JACKSON, Registrar-General.
General Register and Record Office of Shipping and Seamen
32, Basinghall Street, London, E.C.

IN our last issue we reproduced a paragraph from the *Gazette* with reference to the new material invented by Dr. Dennys for coating the bottoms of ships, and it is encouraging to steam and iron shipowners to be able to state that the trials which have so far been made have proved highly satisfactory. The Straits steamer *Japan*, upon which a patch of the paint was applied some six months ago, has gone into dock, and the result proved eminently satisfactory to the dock authorities, the owners, and all who went to examine it, the portion so painted being almost clean, while the rest of the hull below the water line was foul with barnacles and other excrescences. The *Benmore*, of the same line, has just received a complete coating, while other vessels have been partially coated to give the paint a trial. Some other steamers which were experimented upon about the same time as the *Japan* will shortly be docked, when the resisting properties of the paint will have been fairly determined. We believe that this is not the result of a sudden finding, but the fruits of many years' work, and great credit is due to the energy and perseverance which have been shown by Dr. Dennys in an enterprise which we trust may prove as remunerative to the inventor as the present results seem to prove it to be useful to all steamship owners. We should add that plates coated without priming and submerged for six and a half months show no trace of any action of the iron. We understand that nearly all the shares of the proposed company have been privately bespoken, and that steps will at once be taken to put matters in train.—*China Express*.

EDITORIAL NOTES.

THE horrible disaster on the Solway Steamship only serves to point out more forcibly a firm conviction in our mind that all so-called accidents are referable to culpable negligence. There are two classes of people who are mainly responsible for all accidents, those who are indolent and those who are selfish. Though these failings are not, generally considered, very culpable or criminal, they are frequently as much the cause of great disasters, loss, and death to innocent people at large, as are the recognized evils of malice, hatred, thieving, or robbery. Nothing can excuse the carrying of a cask of inflammable oil or spirit on the deck of a ship, and more particularly on the deck of a steamer carrying passengers. No doubt it is often done without any consequent disaster, and, in this case, no harm was thought likely to come of it. That is how ninety-nine out of a hundred accidents are caused by those who are too indolent to think of probabilities and to provide against them, or by those who are too dishonestly selfish to take the trouble to carry out such precautions when known to be advisable. It may seem a hard thing to visit the consequences of such horrible disasters upon the stupid or selfish cause who did not think, or who having thought, did not consider it mattered; but all departure from honesty or thoroughness in work to the minutest details is grossly culpable.

THE electric light seems likely to have as large and varied an adaptation on board ship as on land. In fact, the conditions on board ship in the large engine power always running are exceptionally favourable to the cheap and easy production of the electric light. One of the chief drawbacks in the arrangements hitherto employed for the production of the light whilst in night action, has been the exposed situation of the lamp itself, and of the men directing its operation for the throwing of the beam in any required direction. Some very valuable and interesting modifications have just been introduced and experimented upon on board the *Sultan*. The modifications are introduced in the apparatus for throwing a beam of electric light to detect torpedo attack, so as to bring all the chief parts and the men in charge under cover. This is most important, as probably the first efforts of night attacking torpedo boats would be to disable the electric light and kill the attendants by their machine guns. The improved apparatus consists of a long vertical tube projecting up from between decks, and which can be elongated to a sufficient height when in action. This tube acts as a conductor to the beam of light from the electric light between decks. The top of the tube is covered with a hood containing a mirror, 3 ft. in breadth and 4 ft. in height, mounted on a horizontal pivot, so that the mirror can be adjusted at any angle of depression and elevation by gearing from below, as the hood can also be rotated round the tube, carrying the mirror with it. It is evident that the beam can be thus directed to any spot it is required to illuminate.

THE engine-room artificers are being brought into considerable prominence in the new arrangements of the engineer service in Her Majesty's Navy. Increased responsibilities are being thrown upon them, and consequently higher requirements. To obtain such men, however, who are always able to command high wages on shore, special inducements must be offered. We see that this is now being done in the matter of counting time towards increased pay. The engine-room artificers are also to be considered as qualified to take charge of the engines in place of an engineer officer when required, and, whilst in that position, is to get the allowances of the latter. The artificers are only to become qualified for such promotion after certain term of service, and after having obtained a certificate of competency to take charge of the engines. The preference for promotion to such responsible duties will thus always fall to those who are qualified by time and a certificate for the post. The holding of such post, we understand, to be only temporary during emergency, as the object of the present re-organization is to relieve the engineer officers of the mere mechanical drudgery of their office, and thus more clearly to establish them as gentlemen on a social equality with their brother officers of the other branch of the service.

In spite of anti-corrosive paints and protections, the hulls of our Indian troop-ships are found to be very much the worse for wear. So much so, that something like a panic as to their condition has set in amongst the dockyard authorities. These vessels were launched in 1866, and have lately been extensively repaired as to their decks, cabins, and above-water fittings. As, however, some anxiety has lately been felt at head-quarters as to the condition of their hulls under the water line, the *Euphrates* has been laid up and almost entirely gutted at Portsmouth. The result of the survey has shown that the work was not done a moment too soon, and, as a consequence, the *Serapis*, *Jumna*, and *Crocodile* are to be similarly laid up early in the spring, and the *Malabar* in the autumn. As this additional work will throw much strain upon Portsmouth dock yard, and the troop-ships will monopolize most of the long summer days, it appears that the other squadrons will come very short for repairs, and the need must be grave indeed to require such a monopoly of attention.

It is sad to realize, from the letter of Mr. Andrews to a daily contemporary, that there can be so much ignorant or malicious carelessness amongst sailors of any description in the matter of submarine cables. Such cables are an inestimable boon to all civilized nations, and would not imagine that there can be any sailor afloat who is not aware of the existence of such cables, and who does not know their value and feel the respect that is their due. And yet we find, from Mr. Andrew's statements, that cables are frequently broken by ships carelessly dragging their anchors across the line of the cable, or anchoring over it, although they are laid down conspicuously on their charts. Again, trawlers, when they have fouled the cable with their nets and brought it to the surface, do not even take the trouble to release it and lower it again, but have the ruthless barbarism to cut the cable as the easiest mode of release. In the case also of repairs being carried out at sea, the cable ships are necessarily fixtures, for the time being, to the cable at the point of splicing, and notice is put up conspicuously to that effect. And yet ships and fishing boats bear down upon these repairing vessels in apparently the most malicious way, obliging the telegraph vessel to cut adrift, and undo the work of hours or perhaps days. It is difficult to realize also what particularly animosity can be aroused by the buoys which are laid out by the telegraph people to mark positions of repair, or carrying the cable end during repair, and yet these inoffensive buoys are so frequently destroyed as to imply more than mere carelessness. These indefensible aggressions upon public convenience will probably, sooner or later, produce special legislation against them, but the best protection lies in the gradual but sure progress of knowledge and good feeling between nations, which we hope to see rapidly increase in our own generation.

THE ROTH PATENT SEA SAFE.

On Thursday, at the Royal Albert Dock, North Woolwich, there was an exhibition of Mr. A. D. Roth's patent for ensuring the safety of mails, specie, jewellery, and other valuables, in case of wreck, fire, or accident at sea. It presents the appearance of a pear-shaped buoy, strongly constructed of steel having a considerable amount of elasticity, which would be of advantage in case of its dashing against a hard substance. It is about seven feet high, and five feet across its widest part, and has two or three compartments, each of which is strongly secured inside the buoy. On the top is an automatic bell, which, with the luminous paint the "safe" is coated with, would make its position known by day or night. The safe, being made in various sizes, could be carried by any vessel either on deck or below, and, in case of accident, could be immediately set free, thus relieving the captain and officers of anxiety with regard to the valuables on board. The specimen safe shown on Thursday was surmounted by a bright nickel silver globe, which it was at first thought would help very materially to make the apparatus visible when floating about in the sea in bright weather; but the opinion was expressed that luminous paint would better answer the purpose. In addition to the security of property, the safe would act as a life-buoy, being fitted with hanging life ropes. It having a displacement of several tons, the safe would support a considerable number of people until rescued by the ship's boats or passing vessels. Mr. Roth was present to give explanations, and the weather being somewhat rough, the "riding" qualities of the safe were tested somewhat better than they would otherwise have been, though, of course, very far short of what would happen in the event of a wreck. Mr. Roth was much complimented upon his invention, which Captain Walker (late of the *Great Eastern*) has suggested would be of value, not only in saving life and property at sea, but in landing mails or despatches at any such places as the West Coast of Africa. The invention is certainly worthy of the attention of shipowners and underwriters.

AN ACCOUNT OF EXPERIMENTS MADE BY A BOARD OF UNITED STATES NAVAL ENGINEERS WITH SCREW PROPELLERS OF DIFFERENT MATERIAL AND DIMENSIONS APPLIED TO THE UNITED STATES FISH COMMISSION'S STEAMER "LOOKOUT" WITH THE HULL COPPERED AND NOT COPPERED.

By Chief-Engineer Isherwood, U.S. Navy.

From the Journal of the Franklin Institute.

(*Continued from page* 176.)

RESULTS.

The experiments allow the difference between the resistance of the hull when coppered and when uncoppered to be determined. The mean speed of the five experiments *A*, *B*, *C*, *D*, and *E*, with the uncoppered hull (line 2, Table No. 2) was 9·9741 geographical miles per hour; and the mean thrust of the screw, expressing the resistance of the vessel, was 1814·1283 pounds (line 4, Table No. 2). The mean speed of the two experiments, *F* and *G*, with the hull coppered, was 9·8442 geographical miles per hour, and the mean thrust of the screw was 1612·0248 pounds. The latter quantity increased in the ratio of the squares of the speeds 9·9741 and 9·8442 geographical miles per hour, becomes 1654·8370 pounds, which compared with the 1814·1283 pounds, shows that leaving off the copper from the exterior immersed surface of the hull, increased its resistance 12·5372 per centum over its resistance when coppered.

The experiments also allow the determination to be made of the power of the speed in which the resistance of the hull increased for the interval between the extreme experimental speeds of 9·5346 (experiment *A*) and 10·4190 (experiment *D*) geographical miles per hour. For this purpose, the mean of the speeds and of the corresponding resistances of the hull in experiments *A*, *C*, and *G*, in which the speed did not vary enough to sensibly influence the result, will be taken for one speed; the mean of the speeds and of the corresponding resistances of the hull in experiments *B*, *E*, and *F*, in which the speed did not vary enough to sensibly influence the result, will be taken for another speed; and the speed and resistance of the hull in experiment *D* will be taken for the last speed. The resistances of the hull, line 4, in experiments *F* and *G*, during which the hull was coppered, will be equated for those in the remaining five experiments during which the hull was uncoppered, by multiplying them by the 1·125372 in the immediately preceding paragraph.

The mean speed of experiment *A*, *C*, and *G*, was

$$\left(\frac{9{\cdot}5346+9{\cdot}6264+9{\cdot}7493}{3}=\right) 9{\cdot}6368 \text{ geographical miles per hour;}$$

and the mean corresponding resistance of the hull was

$$\left(\frac{1650{\cdot}9925+1688{\cdot}6734+\overline{1580{\cdot}2261\times 1{\cdot}125372}}{3}=\right) 1706{\cdot}0027 \text{ lbs.}$$

The mean speed of experiments *B*, *E* and *F* was

$$\left(\frac{10{\cdot}0974+10{\cdot}1929+9{\cdot}9390}{3}=\right) 10{\cdot}0764 \text{ geographical miles per}$$

hour, and the mean corresponding resistance of the hull was

$$\left(\frac{1851{\cdot}0375+1909{\cdot}3913+\overline{1643{\cdot}8234\times 1{\cdot}125372}}{3}=\right) 1870{\cdot}1139 \text{ lbs.}$$

The speed of experiment *D* was 10·4190 geographical miles per hour, and the corresponding resistance of the hull was 1970·5470 pounds.

The experiments with the closely approximating speeds have been grouped and their mean results taken, because the greater the number of observations included the nearer accurate is the final determination.

From the above it appears that the resistance of the hull for the increase of speed from 9·6368 to 10·0764 geographical miles per hour was in the ratio of the 2·0590 power of the speed. Had the resistance for the speed of 10·0764 miles been 1865·1949 pounds instead of 1870·1139 pounds, it would have increased exactly as the square of the speed; the difference of 4·9190 pounds is only 0·0026 per centum of the experimental resistance in excess.

There also appears from the above that the resistance of the hull for the increase of speed from 10·0764 to 10·4190 geographical miles per hour was in the ratio of the 1·5646 power of the speed. Had the resistance for the speed of 10·4190 miles been 1999·4435 pounds instead of 1970·5470 pounds, it would have increased exactly as the square of the speed; the difference of 28 8965 pounds is only 1·4664 per centum deficit of the experimental resistance.

Finally, there appears likewise from the above, that the resistance of the hull for the increase of speed from 9·6368 to 10·4190 geographical miles per hour was in the ratio of the 1·8472 power of the speed. Had the resistance of the speed of 10·4190 miles been 1994·1875 pounds instead of 1970·5470 pounds, it would have increased exactly as the square of the speed; the difference of 23·6405 pounds is only 1·1997 per centum in deficit of the experimental resistance.

It is obvious that the slight differences found between the experimental resistances, and what these should be according to the ratio of the squares of the speeds, are so small that they may be fairly attributed to errors of observation and assumption. In fact, the data evidently cannot be relied on as to any greater accuracy, and the conclusion is, therefore, warranted that within the experimental speeds the resistance of the hull of the *Lookout* at different speeds varied as the squares of the speeds.

In experimenting with different propellors for the purpose of ascertaining their relative economic merits, that is to say, the relative percentage which they apply to the vessel propulsively of the power they receive from the engine, care should be taken that in every experiment the same speed of vessel be maintained, which equality eliminates all question as to the law of variation of resistance of the hull in function of its speed. If that resistance increase as the squares of the speeds, then the accuracy of the results is not affected by variations of the vessel's speed because the slip of the same propeller would remain constant at all speeds, the reaction it obtains from the water varying always as the square of its revolutions in equal time. But if the resistance of the vessel increase in a higher ratio than the square of the speed, then the slip of the same propellor would be proportionally greater at higher than at lower speeds of the vessel, and the propellor experimented with at higher speed would, relatively to another experimented with at lower speed, give a less economic result than if it were experimented with at the same speed. At the higher speed there would be proportionally more power expended in the slip, and consequently more power expended in overcoming the resistance of the water to the surfaces of the propeller moving in it. In other words, at the higher speed of vessel the same propeller will apply to it propulsively a less percentage of the power received from the engine than at the lower speed, if the resistance of the vessel increase in a higher ratio than the square of its speed.

Assuming, in the case of the experiments with the screws of the *Lookout*, that the resistances of the vessel at the different speeds varied as the square of those speeds, an assumption warranted by the experimental results, the following would be the resistances of the coppered vessel for a speed of 10 geographical miles per hour, deduced from the experimental resistances at the experimental speeds in the ratio of the squares of these speeds to the squares of 10:—

Screw.	Resistance of vessel in pounds at 10 miles per hour.
A	1613·78
B	1613·24
C	1619·28
D	1613·02
E	1633·06
F	1664·06
G	1662·54
Mean,	1631·28

In the above determinations the experimental resistances with screws *A*, *B*, *C*, *D*, and *E* have been reduced in the ratio of 1·125372 to 1, as the vessel in those cases was not coppered, that ratio expressing the effect of the coppering.

An examination of line 23, Table No. 2, shows that screws *B*, *C*, *D*, and *E* had the highest economic efficiency; also, that their economic results were sensibly the same, as they all applied propulsively to the *uncoppered* vessel, 70 per centum of the net horse-power developed by that engine, that is to say, 70 per centum of the power applied to the crank-pin. And, if the proper correction be made for the diminution of the vessel's resistance due to coppering, these screws would have usefully applied to the *coppered* vessel 71·3117 per centum of the net horse-power developed by the engine. Now, screws *B*, *C*, *D*, and *E*, though having the same diameter and number of blades, varied largely in pitch and in the fraction used of the pitch, the pitches being 7·500, 7·500, 8·625, and 9 feet, and the respective fractions used of these pitches being 0·5283, 0·2703, 0·1994, 0·3549, showing that for a given diameter the pitch and fraction used of the pitch may vary considerably without affecting the economic performance of the screw. This arises from the fact that the losses of useful effect by the screw are, 1st, that which is due to its slip, and 2nd, that which is due to the resistance of the water on the surface of its blades; including, in 2nd, the direct resistance of the forward edges of the blades. And that the first loss cannot be diminished without the 2nd loss being increased, *pari passu* and *vice versa*. The slip depends on the proportion of the acting surface of the screw in a given time, relatively to the resistance of the vessel, and can only be lessened by adding more of such surface, which, with a given diameter of screw, can be effected by either diminishing the pitch or increasing the fraction used of the pitch. But, as the loss by the resistance of the water on the screw surface is in direct proportion to that surface multiplied by the square of its velocity, any increase of the acting surface is necessarily accompanied by increased loss due to this cause. The two kinds of loss are found experimentally to be so balanced in nature that, within very considerable limits, whatever can be diminished of one kind is attended by an almost exactly equivalent increase of the other kind.

Screw *G* applied to the coppered vessel, and having the same diameter as screws *B*, *C*, *D*, and *E*, with the pitch of 7·9 feet, which lies within the limits of their pitches, gave a utilization of 69·8750 per centum of the net power developed by the engine, instead of the utilization 71·3117 per centum, that would have been given by those screws had they been applied to the coppered vessel. This shows an inferiority of $\left(\frac{71{\cdot}3117 - 69{\cdot}8750 \times 100}{71{\cdot}3117} = \right)$ 2·0147 per centum for screw *G*, which is probably owing to the excessive fraction used of its pitch, namely, 0·5736, the largest fraction used in the cases of screws *B*, *C*, *D*, and *E* being 0·5283. The increased power required to overcome the resistance of the water to the surfaces of screw *G*, owing to the increased fraction used of its pitch over the largest fraction used with screws *B*, *C*, *D*, and *E*, was probably greater than the lessened power expended in the lessened slip consequent on the use of that greater fraction of the pitch.

(*To be continued.*)

ON THE PROGRESS AND DEVELOPMENT OF THE MARINE ENGINE.

By Mr. F. C. Marshall, of Newcastle-on-Tyne.

(*Continued from page* 180.)

We have now considered three of the means of increasing efficiency, but it is clear that anything that can be done with the present boiler is limited by one measure, namely, the power of the chimney. Mr. Perkins has shown us that in his boiler, with slow combustion, he can develop in his engine 106 indicated horse-power, from 600 square feet of surface, on a consumption of under 1·7 lb. per indicated horse-power, with a working pressure of 350 lb. per square inch, and weight of boiler and appurtenances—as the writer is informed—only half that of the ordinary form. But it may be doubted whether the tubes forming the furnace, and the rows immediately over the fire, would not very rapidly burn out from the expulsion of the water, under the heat of combustion of even the ordinary 20 lb. to 30 lb. of fuel per square foot of grate.

Mr. Perkins has, however, shown us in the working of his engine and boiler that cylinders can be worked at 350 lb. pressure and corresponding temperature, without oil or other lubricants than that of the steam itself; and that boilers can be worked at sea with pure water—themselves making up their own waste—and can be kept absolutely clean and free from injurious deposit. These are important gains to our knowledge, and may no doubt bear results in the future.

The application of forced draught to the furnace has been several times used in marine boilers within the last decade and promises more than any other method a way to largely increased efficiency as well as reduction in weight.

For nearly fifty years the locomotive boiler has been in operation, and, under the action ot the blast pipe, has been the most powerful evaporative machine in existence for its weight. As has been already noticed, it does the same work on under one-third of the weight of the marine boiler. In the case of a vessel of 3,000 tons, with engines and boilers of 1,500 indicated horse-power, the introduction of locomotive boilers with forced draught would place at the disposal of the owner 150 tons of cargo space, representing £1,500 per annum in addition to the present earnings of such a vessel. The engine space of such a vessel is shown in Figs. 19 and 20, with both the ordinary and locomotive form of boiler for comparison.

Mr. Thornycroft has for some years used the locomotive form of boiler for his steam launches, working them under an air pressure —produced by a fan discharging into a closed stokehold—of from 1 in. to 6 in. of water as may be required. The experiments made gave an evaporation of 7·61 lb. of water, from 1 lb. of coal at 212 deg. Fahr., with 2 in. of water pressure, and 6·41 lb. with 6 in. of pressure. These results are low; but it is to be remembered that the heating surface is necessarily small, in order to save weight, and the temperature of the funnel consequently high, ranging from 1,073 deg. at the first pressure and 1,444 deg. at the 6 in. With the ordinary proportions of locomotive practice the efficiency can be made equal to the best marine boiler, when working under the water pressure usual in locomotives, say from 3 in. to 4 in., including funnel draught.

It has fallen to the lot of the writer to fit three vessels recently with boilers worked under pressure in closed stoke-holds. The result, even under unfavourable conditions, were very satisfactory. The pressure of air would be represented by 2 in. of water, and the indicated horse-power given out by the engines was 2,800, as against 1875, when working by natural draught, or exactly 50 per cent. gain in power developed.

The boilers here alluded to were those which, for distinction, we will call the "Navy boiler," shown in Figs. 10 and 11 and give, under ordinary conditions, very excellent results. But they have the disadvantage of greater length and weight than the locomotive form, which, more than any other, in the writer's opinion, promises to meet the future requirements of the marine engineer. Two objections to its use on board ship have hitherto existed: first, it is supposed they must be deficient in steam room, and therefore very liable to prime; and, secondly, there is difficulty in keeping clean, and liability to become salted up.

The first objection is entirely one of construction, and need not exist. The boiler may be made with ample steam room by the addition of a steam dome, or by making the firebox casing higher than the barrel of the boiler, so as to be of sufficient capacity, without increasing the weight of water, as shown in Figs. 19 and 20. The second objection can be met, and is now met in most services, by the increased care now taken by all engineers of their boilers, both in working, and when in port. The construction of the boiler need not be such as to make it any less accessible than the present marine boiler; and there is no reason why the water need be worse than that used for locomotives on land. As a rule it is much better, when surface condensers are attended to. The principal difficulty is the "human factor;" and it must be admitted that marine engineers are much better educated and and more intelligent now than ten years ago, and are becoming more and more so. It is also to be considered that, should their responsibility be increased, they are the more likely to become fitted for it.

Great advantages are to be gained by the introduction of another form of boiler combined with forced draught, and the locomotive form is that presenting the fewest objections.

In referring to the examples given in Table I., it was shown that saving was effected equal to that calculated by the use of higher working pressures, indicating that further progress lies in the same direction; although the saving may be fractional, and cannot possibly equal past results for the same increment of pressure. Table IV. shows:

1. The quantity of steam and coal used at pressures varying from four to eleven atmospheres, assuming the ratio of expansion to be varied so as to produce the same terminal and back pressure.
2. The same, assuming six expansions and the same back pressure.
3. The same, assuming eight expansions and the same back pressure.

The total working pressure of to-day may be accepted as 105 lb., or equal to seven atmospheres. If it were boldly accepted that eleven atmospheres, or 165 lb., were to be the standard working pressure, the result would be a gain of 14·55 per cent., provided no counteracting influence came into play. Of course, there are forces which war aginst the attainment of the full extent of this advantage, viz., the greater condensation in the cylinders and loss in the receiver or passages.

In regard to the former, it may be questioned whether by steam jacketting the high-pressure cylinder, correctly proportioning the steam passages, and giving a due amount of compression in both cylinders, this may not be reduced far below the generally received notion; and the latter cause of loss may be considerably reduced in its effect by a more carefully chosen cylinder ratio. The ratio usually adopted, between 3·5 and 4 to 1, whether the pressure be 70 lb. or 90 lb., may well be questioned in view of the results shown in the case of Nos. 6, 15, and 17 in Table I. There, with a cylinder ratio of 2·95 to 1, the economic performance is very good, and equal to any with the higher ratio; and it may be added that the cases quoted are amongst the most reliable and trustworthy of the list.

A lower cylinder ratio has another advantage of considerable value, viz., that the working pressure can be much reduced as the boilers get older, while, by giving a greater amount of steam, the power may be maintained—at an extra cost of steam, of course, but not so great a cost as with higher ratios. This fact was mentioned by Mr. Macfarlane Gray in the discussion on Sir Frederick Bramwell's paper in 1872.

The starting has usually fixed the cut-off in the high-pressure cylinder at about 0·6, and the ratio of expansion has decided the ratio of cylinders. The use of separate starting valves in both cylinders obviates that necessity. The difficulties in the way of taking advantage of the higher economic properties of greater pressures than hitherto used on board ship, are, it is submitted, not insuperable, and it would be to the interest of all that they should be firmly and determinedly met.

The quantity of steam used in the compound receiver engine and and Woolf engine respectively, are stated by Mr. D. K. Clark, in his Manual of Rules, Tables, and Data to be:—

	Per Indicated Horse-Power.
Receiver engine	18 to 20 lb.
Woolf engine	20 to 21 lb.

It is a remarkable coincidence that the long voyage results given in Table I. exactly confirm Mr. Clark's figures. It may therefore be accepted as an average result that the Woolf engine, as usually arranged, will use 10 per cent. more steam than the receiver engine for the same power. Of the three-cylinder receiver type, the data are insufficient to form a definite opinion upon; but so far the general working of the Arizona is stated to be as good, economically, as any of the two cylinder receiver class.

It is only right to mention here that the results referred to are very seriously affected by the condition of the valves and gear at the time; and still more by the setting of the valves, and the relations of the admission, port-opening, release, and compression, to the movements of the piston. The efficiency of an engine may be reduced enormously by carelessness in this matter, and when efficiency is of such vital importance, these matters of detail cannot be too strongly urged upon steamship owners. It is not too much to say that nine-tenths of the engineers in charge of engines know nothing of the condition of their valves, and it is not till serious waste or mishap occurs, that they are thought of.

The surface condenser remains as it was ten years ago, with scarcely a detail altered. In most engines it remains a portion of the framing, and as such adds greatly to the weight of the engine. It is a question seriously worth consideration whether or no the surface of tubes can be reduced. The practice at present is to make the surface one-half the boiler surface as a minimum, that is, equal to about 2 square feet per indicated horse-power. In practice, the writer has found 1·4 square foot per indicated horse-power to maintain a steady vaccum of 27½ in. The only experiments on this subject of practical and accurate character are those conducted by Mr. B. G. Nichol, of this town, an account of which appeared in *Engineering*, December 10, 1875. It was found that when the water flowed through the tubes with a velocity of 100 ft. per minute, 1 square foot was quite sufficient to transfer 527 units of heat from the vapour of the condenser to the water, for each degree Fahr. of effective difference of temperature. Now in general we only have 200 units passing through for each degree of effective difference, so that even with water passing through at the slow velocity named, there is a large margin for the dirt in the tubes frequently found in condensers. Then again, an engine using 22 lb. of steam per indicated horse-power must require more surface than one using 17 lb.; and if 2 square feet be necessary for 22 lb., while, by increasing initial pressure, the quantity of steam can be reduced to 16 lb. per indicated horse-power, we should only require 1·45 square foot per indicated horse-power, to give the same vacuum, if the condensing water remained the same.

The method generally in use, of passing water through the tubes, is much more efficacious than exhausting through, as is sometimes done in Her Majesty's Navy. The circulation is never so perfect in the latter case, and much more water is carried. The ordinary plan gives more control over the quantity, and also better circulation of the water.

The air and circulating pumps, for engines of 1500 indicated horse-power and under, are, as a rule, worked entirely by levers attached to the low-pressure connecting-rod crosshead. They thus help to balance the piston and rods of that engine. The circulating pump is made single or double acting; the single acting has the advantage of adding to the balancing of the weights, and offers no obstruction to the flow of water; the double acting has the effect of checking the column at each stroke, and is not so easy in working.

The Gwynne centrifugal pump is extensively used for circulating and bilge purposes, and is a very valuable auxiliary to the main engine.

The extended use of steel offers great advantages for the reducing of weights, and especially in the form of hollow shafts, such as are now being manufactured by Sir Joseph Whitworth & Co. On this system, in a 10-in. shaft, a hole is run 4 in. in diameter, reducing the weight 16 per cent., while its strength is only reduced 2·56 per cent.; or, if the hole were increased to 5 in. the weight would be reduced 25 per cent. and the strength only 4·25 per cent.; and it is a question whether the weight could not be further reduced by giving a lower nominal margin of safety, which it would seem might be done on account of the greater elasticity of form, as well as elasticity and homogeneity of material. The surface presented by a steel shaft to the bearings is also—it is not too much to say—almost infinitely more perfect than the forged iron shaft with its reeds, open texture, and iron cinder, from which marine engineers suffer so much. The friction must therefore be greatly reduced.

The writer has just completed six pair of engines for three twin-screw ships, having steel shafts of 10 in. diameter, and has in each case run the engines at 120 revolutions per minute, while indicating 1380 horse-power from each pair, for ten to fifteen hours without stopping; and in no case has a single bearing or crank-pin warmed or had water applied, the surfaces on examination being perfect.

In these engines all working bolts, pins, and rods, except the piston and connecting-rods, are of steel, all rods in tension being loaded to 8000 lb. per square inch. The boilers are of the Navy type, made throughout of Siemens-Martin steel plates, rivetted with steel rivets, all holes drilled. Furnaces are welded and flanged; the tubes are of brass. In comparison with an ordinary merchant steamer's iron boilers of the double-ended type, they weigh, including water and all appurtenances, as follows:—

	Double-ended Type.	Navy Type.
Weight, tons	135	146
Indicated horse-power... ...	1400	2760
Draught...	Natural	Forced.

The use of steel castings is becoming considerable; they give great strength, but unfortunately the still persistent presence of blow-holes prevents their strength, and their wearing to a polished surface, being relied on to the extent that could be wished.

For our large steamers steel-built crankshafts must come more and more into use. The constant failure of iron cranks, even when built up, is too serious a question for the shipowner to let alone long. It is important to note Mr. Holt's remarks on his return to the old-fashioned mill-engine form of crank. The single bearing of great length on the end of a long length of screw shafting—the crank-pin with small surface velocity, the simple crank, made, as it can now be made, to be practically solid with the shaft—are all great steps in the way of simplicity; provided only shipowners care to adopt the single engine, which, even if 10 per cent. more costly in fuel, has much to commend it.

The cast-steel propeller blades introduced by Messrs. Vickers, are being more largely used; the reduction in thickness enables them to be much more easily driven.

The screw propeller is still to a great extent an unsolved problem. We have no definite rule by which we can fix the most important factor of the whole, namely, the diameter. Mr. Froude has pointed out that by reducing the diameter, and thus the peripheral friction, we can increase the efficiency; and this is confirmed by cases—of Iris reduced 2 ft. 3 in., and the Arizona

Ratio of net coal, that for 105 lb. being unity ...	1·053	1·043	1·021	1·	0·991	0·972	0·966	0·962
" " 60 " " ...	1	0·966	0·945	0·925	0·917	0·897	0·894	0·89

reduced 2 ft. This must of course be qualified by other considerations. The ship has by her form a definite resistance, and a certain speed is required; if the propeller be made too small in diameter, the ship will not be driven at the required speed, except at serious loss in other directions.

This question is too large and complicated to be dealt with here, and should, in the first instance, be made the subject of careful and extended experiment, on which a separate paper should be written. The writer's object is to point out the important bearing this question has upon the marine engine. We have shown the importance of the reduction of weight to the shipowner; the smaller the propeller the smaller the engine needs to be to drive it, and therefore the less the weight to be carried; but to produce the same result in driving the ship the propeller will need to be turned faster, and the faster it can be turned, consistent with efficiency and small wear and tear, the better. That we are a long way within our powers, in our ordinary practice, in this latter respect, is proved by the engines of torpedo vessels developing 470 indicated horse-power at 443 revolutions and 886 ft. piston speed per minute; the Iris developing 3857 indicated horse-power at 99 revolutions and 582 ft. of a 75 in. piston per minute; and the engines recently constructed, before alluded to, giving out 1400 indicated horse-power at 124 revolutions, and 724 ft. per minute of a 60 in. piston. To do this, however, the working parts must be carefully balanced, a matter very much neglected, and one which leads to great wear and tear in shafts, crank-pins, &c. Such effects, not being considered sufficiently in the first instance, are urged against the adoption of higher velocities, not specially in the piston, but what is far more important, in the speed of revolution, which, as experience is showing us, may be vastly increased to the advantage of all, and specially of the shipowner, whose interests it is the first interest of our profession to promote.

To sum up the whole. Progress has been made during the past nine years, and in the following particulars:—

1. The power of the engines made and making show a great increase.

2. Speeds hitherto unattainable are now seen to be possible in vessels of all the various classes.

3. The consumption of fuel is reduced by 13·38 per cent. on the average; and numbers of vessels are now working on much less coal than that average, while the quality of the coal is in nearly all cases very inferior, so that it is not unfair to take credit for 20 per cent. reduction.

4. The working pressures of steam are much increased on the average, and are still increasing; many steamers now being built for 120 lb. per square inch, while 90 lb. is the standard pressure now required.

As increased pressure means increased efficiency, there does not appear any reason why the standard of 150 lb. should not be sought as that of the future; combined with the adoption of the locomotive description of boiler and forced draught. Higher speeds of revolution appear to be desirable, with a view to very great reductions in weight of machinery carried. This implies careful balancing and adjustment of all working parts, as well as of the steam, to the work to be done.

The more general introduction of steel in all its varieties is enabling the marine engineer to adopt means tending throughout to lighten working parts, and to increase velocities, in a way he dared not attempt nine years ago.

In conclusion the writer begs to submit this paper to the Institution as a very imperfect *résumé* of the progress and development of the marine engine, and only as a sequel to that of his distinguished predecessor. His time has not permitted him to go fully into the many questions arising out of the subject, and he asks that it may be received only as a basis of discussion by the Institution, many members of which are much better able to deal with it than he feels himself to be.

The writer desires to tender his warmest thanks and acknowledgments to the numerous shipowners, manufacturing engineers' marine superintendents, and others, who have so freely supplied him with valuable information for this paper, some at considerable expense and trouble.

He has also pleasure in acknowledging the careful assistance rendered by Mr. A. Blechynden, M.I.M.E., in the preparation of the details and calculations of the paper.

ERRATUM.

"Page 155, Perkins boiler (see Illustration next No.)" should read "see Illustrations pages 255 and 256, Vol. 2." Illustration page 176, Fig. 12, should read 13, and page 178 Fig. 13, should read 14.

A BOAT destined to be propelled solely by electricity has just been completed, according to the French journal *Lumière Electrique*, The owner, M. Tellier, intends to launch it at Boulogne and to cross in it to Folkestone, in company with a friend. The boat is decked, and is about 18 ft. long by about 4½ ft. wide.

LIGHTFOOT'S DRY-AIR REFRIGERATOR.

WE understand that Mr. T. H. Lightfoot, of 116, Fenchurch-street, E.C., has made arrangements with the well-known firm of engineers, Messrs. Douglas & Grant, of Kirkcaldy, N.B., for the manufacture of his patent dry-air refrigerator. This machine, which was illustrated and described in our issue for October last, is now being constructed in various sizes, so as to be made applicable, not only for meat preserving on a large scale, but also for innumerable purposes in the manufactures, where a reliable and cheap cooling power is calculated to be of great utility. A special form is also being constructed for preserving ships' provisions, and the time is perhaps not far distant when the carrying of live stock on board of our large passenger boats will be superseded by fresh dead meat preserved by means of a dry air refrigerator, which would also be available for making the daily supply of ice required for table use.

ANTI-FOULING COMPOSITIONS FOR SHIPS' BOTTOMS.

IN pursuance of our desire to bring under the notice of our readers the most prominent and effectual anti-fouling compositions for iron ships, we have much pleasure in giving publicity to the following interesting facts relative to Gay's marine paints, which are fast coming to the fore on account of their never-failing properties for the prevention of corrosion and fouling, however long the voyage, or in whatever part of the globe.

In the preparation of the priming coats great care is taken that they shall be entirely anti-corrosive, and of such a character that the iron has an affinity for them, and they are consequently very readily absorbed, filling up the pores of the iron, to the exclusion of any corrosive influence from air or water.

The finishing, or anti-fouling, coating is so compounded that it does not dry hard, but is of an exfoliating character, which was so strongly advocated by some of our practical correspondents in previous numbers. It will be seen from a perusal of the following that the requirements mentioned by our correspondents as being essential for a good anti-fouling composition are fully borne out in Gay's Marine Compositions.

The proper protection for an iron ship against fouling is a coating having a constantly clean and self-freeing surface. Such a surface is essential, from the known fact that in parasitic life the young only are possessed of locomotion. Hence the adhesion of living organisms takes place during the earliest condition of fry, and therefore so long as there is any permanent surface for these minute pests to hold on to for their future growth and development, so long will some of the myriads which swarm in the sea be at hand ready to take advantage of any unprotected spot on the ship's bottom.

The same may be said of the minute spores of sea-weeds, and these can never detach themselves.

Such organisms and sea-weeds do not derive the slightest nourishment from the substance to which they adhere. Barnacles and sea-weeds are simply adherent, and whilst it is a very well-known fact that no nutriment is absorbed by either living shelled parasites or by vegetable algæ from the objects to which they are attached, it is very doubtful how far any noxious qualities of the material is injurious to young fry when they first settle upon it. Still more remote is the possibility of injury from such a source to either weeds or parasites when they have attained any considerable advance in age.

For this reason alone it will be seen that the most effectual antidote to the settlement or development of any vegetable or animal growths upon the hull of a ship is the maintenance of a *perpetually clean and renewed surface*, such as would be presented under the condition of a continuous dissolution or flaking, by which the molecules of the substance to which the organisms attach themselves should be quickly liberated from the mass of the protective coating and fall away from the ship's bottom.

Nothing, probably, can prevent the adhesion of parasites, vegetable or animal, on a permanent surface. Once attached, their rapid development takes place, until such is the obstruction to the speed of the ship when her bottom has become fouled, that a diminution of from one to three knots per hour is often the result.

Such retardation of speed is a most serious and reprehensible waste of money in the extra expenditure incurred for coal, wages, probable loss of good markets, and the necessity for frequent docking, outside the important question of the absolute corrosion and waste of the ships themselves. The loss alone for extra coal, under such circumstances, say for a ship of 1000 nominal horse-power, may be represented at something very considerable.

Upon an intimate knowledge of the foregoing facts, Gay's Anti-Fouling Composition was founded many years ago, and, notwithstanding attempts have been made from time to time to pirate it, its compound is still a secret only known to the manufacturer, and it stands pre-eminent for its practical and satisfactory results, as would appear from the numerous excellent testimonials we have read from practical mariners and others who have used it on their ships.

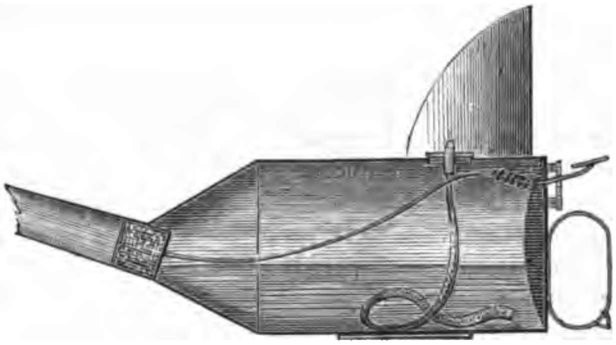
A remarkable instance of the value and durability of this composition is given by the captain of a ship—*The Winefred*—who testifies to a coating of it having been applied to the bottom of the ship, which went a voyage to Australia and the East Indies and back to Australia, and as it was found that she maintained her speed throughout, it was not considered necessary to re-dock her for two years, when she was examined. After that period, she was found to be entirely free from rust and fouling, and her bottom was well preserved.

These compositions are applied in the ordinary manner. No deleterious effects are experienced in their application. They cover well and dry quickly.

Messrs. Brown, Stevenson, & Co., of No. 11, Queen Victoria-street, City of London, and their appointed Agents are the sole vendors of these justly celebrated compositions.

GROOM'S ILLUMINATING OIL-FEEDER.

IT is a well-known fact amongst those who are acquainted with machinery and the oiling of it that more oil is wasted from oil-feeders than is actually put on the bearings at all. This arises very often from the difficulty of seeing where the spout of the oil-can is applied in intricate machinery, and the only way to make sure of some oil reaching the bearing is to pour a large quantity indiscriminatingly over the cap of journal, or, at least, in the neighbourhood of the bearing. Even when this is done, the engineer or attendant cannot be sure that the oil has really entered down the proper channels.



Groom's illuminating oil-can, illustrated herewith, is a very simple but useful invention, to enable the engineer or attendant to see what he is doing. A wick is placed in the can and brought through a burner situated on the top of the can. A reflector is also fixed partially around the light, so as to throw the illumination exactly on the point where the spout of the feeder is being directed. Absolute accuracy can thus be used in supplying the oil, and the light on the can prevents the necessity for any other lamp when oiling in the dark portions of the engine-room or anywhere in the hold. If the light is not required it need not be used, but the advantage of having a light inseparably connected to the feeder, and just throwing the light where required, should render this feeder invaluable to sea-going engineers.

DONOVAN'S BOAT-LOWERING APPARATUS.

THE apparatus hitherto so generally used for lowering out boats is now universally accepted as being antiquated and far from fit for the purpose to which it is applied. The shocking loss of life in the case of collisions or the sudden foundering of iron vessels shows plainly that the time now elapsing between piercing of the hull and the sinking of iron vessels is so short that the utmost care should be taken, and no expense grudged by ship owners to render the lowering of the boats as prompt and secure as possible.

In the matter of the fixing of the boats on chocks inboard when not in use, much valuable time is often lost in casting loose the lashings. How can such lashings be dispensed with, as otherwise the boats may easily be carried away or stove in by heavy seas?

Captain Donovan, a North-country seaman of great experience, has invented a very simple apparatus that seems fully to meet the requirements that we have pointed out, and to render the lowering of the boats an easy, safe, and expeditious operation on the most sudden emergency.

When the boats are not in immediate use they are carried inboard on special chocks, which form part of Captain Donovan's apparatus. The outside chock is movable on a pin or hinge, where it springs from the main standard. A quadrant, *a*, Fig. 1, is also attached to this chock and passes through a slot in the main standard. It is secured in each standard by a pin, or catch, which are operated simultaneously by the rod, *b*.

The lashings also are secured by links, through which a pair of bolts on the deck are run. These bolts are connected by arms and a link, *d*, so that they must be released simultaneously. As the outside chocks fall, and the lashings are released, the boat is free to swing outwards, and thus at once hang from the davit-tackle ready for lowering. The crew should seat themselves whilst the boat was still on the chocks.

The lowering away is now performed from the boat itself by a man stationed at either end, the fall-tackle

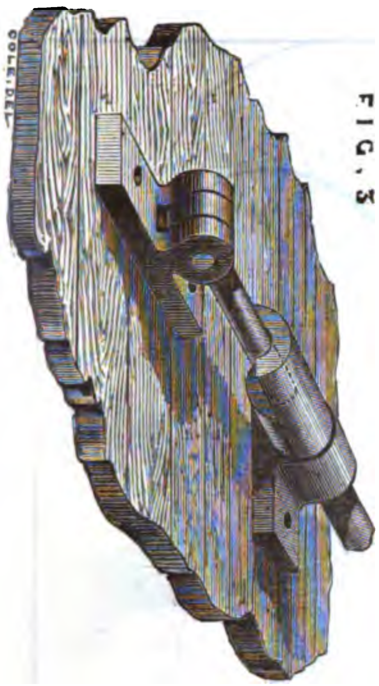


FIG. 3

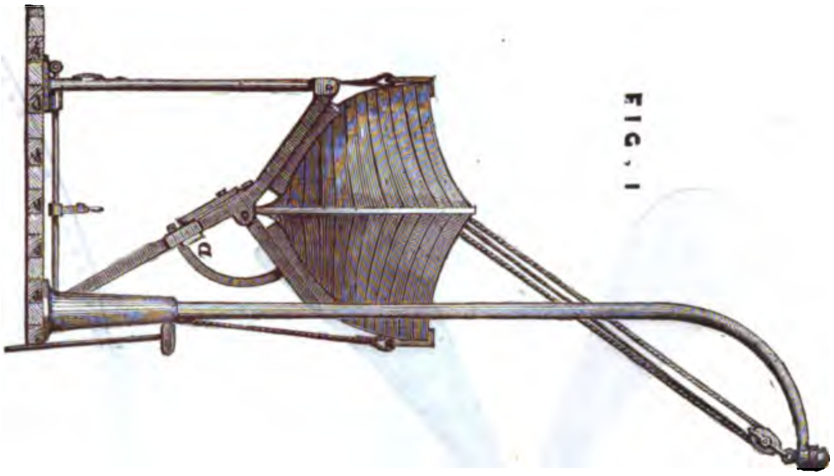

FIG. 1

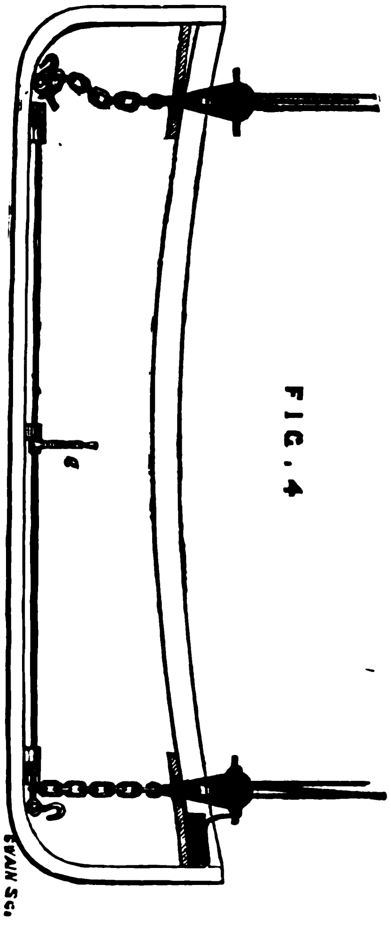

FIG. 4

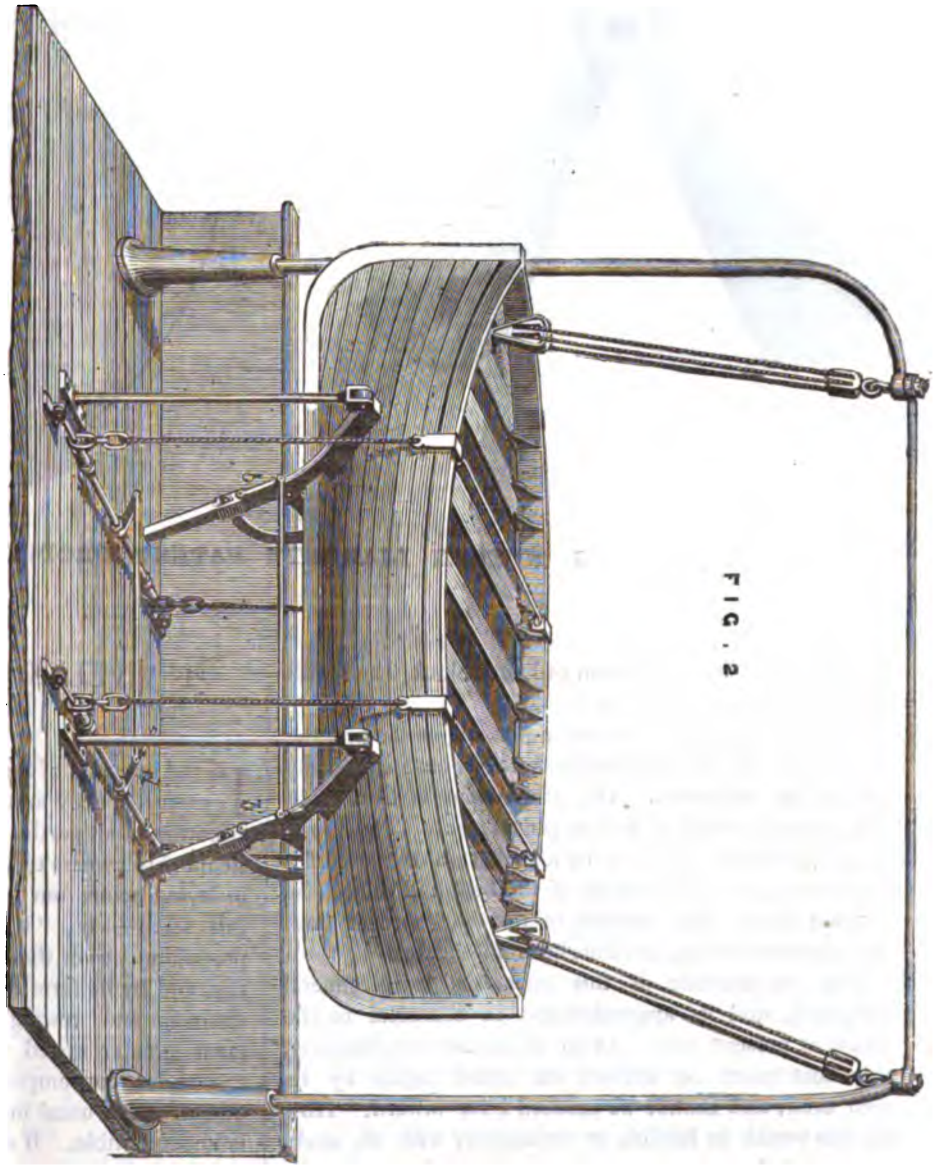

FIG. 2

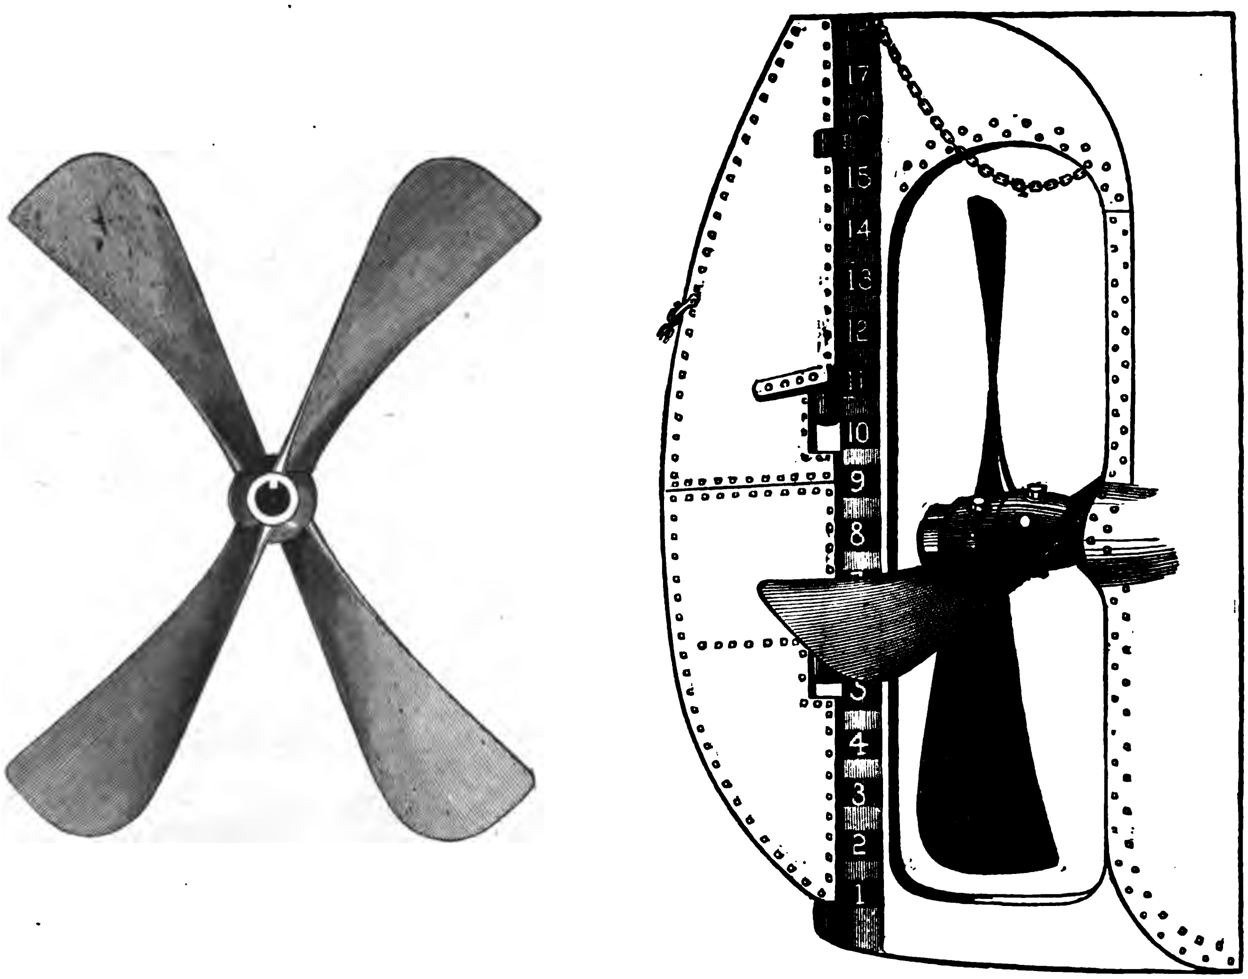
DONOVAN'S BOAT-LOWERING APPARATUS.



J. EVELYN LIARDET'S PATENT PROPELLER.

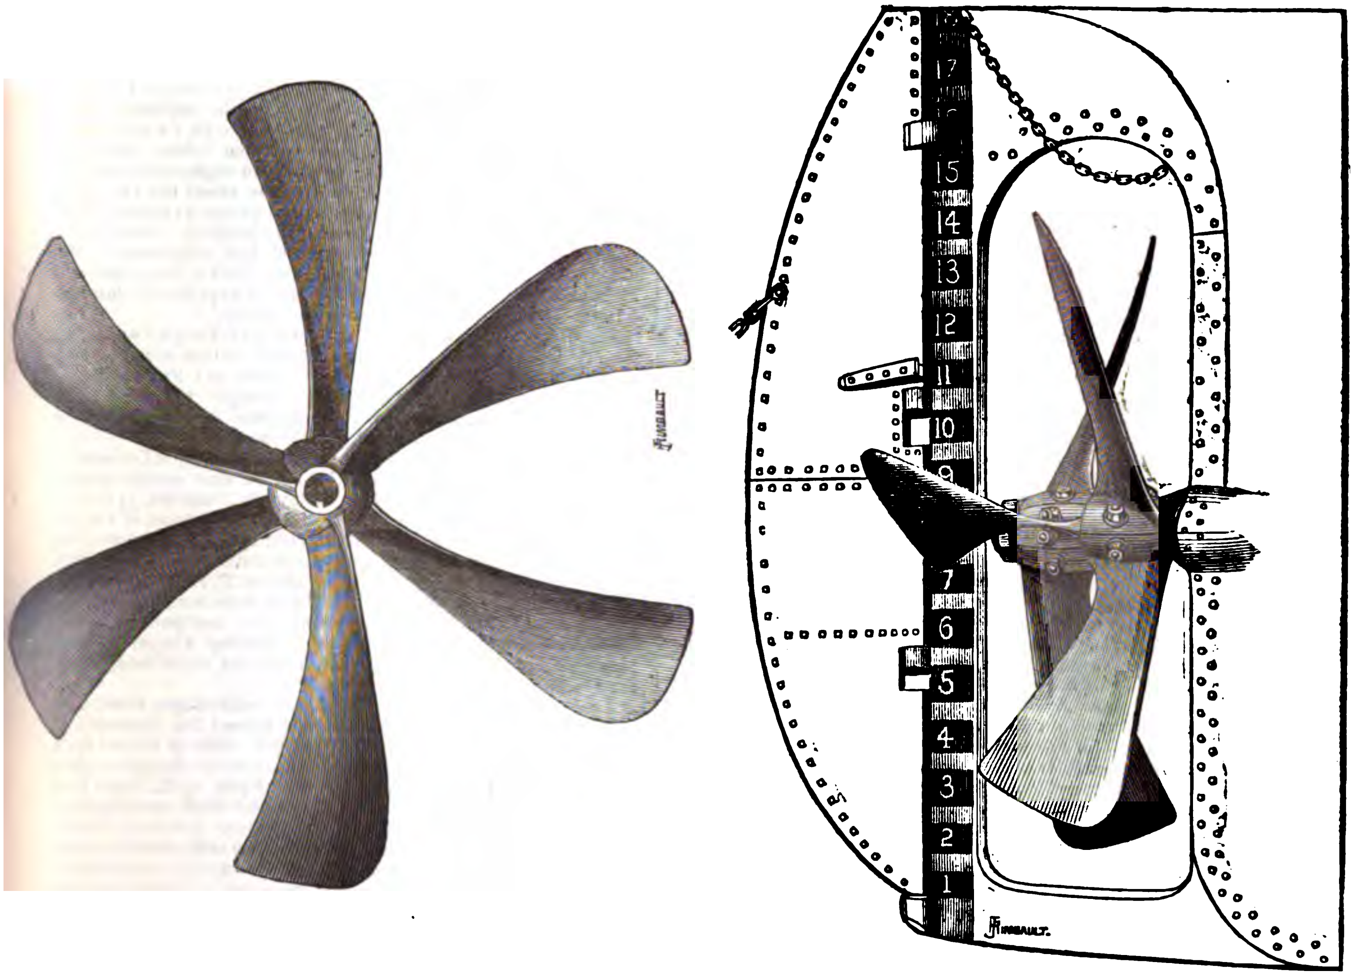
being lowered away from an ordinary block fitted with belay pins at the bottom of the falls.

When the boat reaches the water, or just before, the attachment of the fall-blocks can be instantaneously released at both ends. The attachment is by a chain link, through which a bolt or pin is shot. The pin is hinged, but held in place by a socket on the end of a bar running the whole length of the boat and rotated by a hand-lever. The rotation of this bar releases both pins simultaneously, and thus both fall-tackles.

The characteristic of this apparatus is its general simplicity, and its approximation in character to the tackle at present used. As far as we can see, however, the boat must be hoisted on board again by its own crew, and cannot be assisted from inward. How far this would be feasible or satisfactory with ill, weak, or wounded passengers or crew in the boat, we can scarcely give an opinion.

J. EVELYN LIARDET'S PATENT PROPELLER.

IN the interests of Steam Navigation, Trade, and Commerce, speedy and comfortable passages, we call the attention of all parties interested, especially that of screw steam-ship owners to this propeller. We have pleasure in laying before our readers the advantages claimed for this screw—viz., "it cuts solid water, and gives more propelling power than any other in use. It gives little slip, and by its form forces off the used water, instead of churning and towing it as other propellers do. It gives greater speed with fewer revolutions, and with a smaller consumption of coal in comparison with others. The usual unpleasant and destructive vibration is imperceptible. If ship owners are willing to incur the expense of a hollow and solid shaft working together, one-half of this propeller can be worked to the right and



J. EVELYN LIARDET'S PATENT PROPELLER.

one-half to the left simultaneously, without the liability to break, and it thus fulfils all that is claimed for screws so fitted. The Patentee (Mr. Evelyn Liardet) is satisfied that such *expensive* and *complicated machinery* is *unnecessary*, and, by fitting his propeller as a fixture on the ordinary shaft, so that each blade cuts solid water, all the force that can be obtained from the ship's engines for propulsion is produced without alteration of any kind in the ship. The key way is cut in the boss, and the only expense is the propeller, at a cost not in excess of an ordinary screw." Mr. Evelyn Liardet is well-known to the Mercantile Marine, he being the Inventor and Patentee of the Double Grip Anchor and Spring, and Double Acting Windlass. We regard his description as a common sense one, and comparing it with the diagrams before us, and the models we have séen at No. 14, Fenchurch-street, we express our confidence in this propeller; we are informed that every trial of it has been a success. It may be cast in the solid metal, or with removable blades in the usual way. It possesses another important feature of handiness, one-half only being fitted and removed at a time, half the weight has to be handled in so doing.

At the next Steam Yacht Races in 1882, no doubt the best types of propellers will be fitted to the yachts, and we hope this screw will be among them as, even in the Yacht Fleet, the trials of the various screws cannot fail to have its significance.

Mr. Evelyn Liardet's screw was well tested on Monsieur Baudet's Electric Ship, at the Palace of Industrie, Paris, and answered so well that *Le Yacht* and several French papers refer to it as being well taken up in France, and it is to cross the channel, fitted to Monsieur Baudet's Electric Boat.

We shall give special attention to the Trials of Screw Propellers, and we are impressed an official Government Trial of all the best known screws would be of great service, similar to that by the United States Government, noticed in our issues since August 1st.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of* THE MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Peconic.—The *Peconic*, a brig-rigged iron steamship, built to the order of the Mediterranean and New York Steamship Company, of which Messrs. Phelps Brothers & Co., of Liverpool, are the managing owners, was launched on Oct. 21st from the shipbuilding yard of Messrs. Thomas Roydon & Sons, Queen's Dock, Liverpool. This vessel which is of 1,798 tons gross, has been built on the double bottom system, with water ballast tanks fore and aft. Her dimensions are:—Length, 289 ft.; breadth, 34 ft. 4 in.; depth of hold, 24 ft. 5 in. She is being fitted with engines by Messrs. Fawcett, Preston & Co., and will be supplied with steam-steering gear by Messrs. Bow, M'Lachlan, & Co., Paisley. The *Peconic* has been constructed with a view to the transit of fruit, having ventilators specially adapted to that object. The ceremony of christening was performed by Miss Phelps.

Britannia.—On Oct. 25th, the *Britannia*, a brig-rigged steamship, built to the order of Messrs. Cyprien, Fabre & Co., of Marseilles, was launched by Messrs. Thomas Royden & Sons, Queen's Dock, Liverpool. The dimensions of this vessel, which is capable of carrying a deadweight of 3,300 tons, are as follows: —Length, 337 ft.; breadth, 40 ft.; depth of hold, 27 ft. She will be fitted by Messrs. George Forrester & Co., Vauxhall Foundry, with engines of the inverted direct-acting compound surface-condensing type, having cylinders of 40 in. in diameter for high pressure, and 76 in. for low pressure, supplied with steam at 85 lbs. pressure from two circular boilers. She will likewise be supplied with Harrison's patent steam-steering gear. The *Britannia* will, in addition to cargo space, have accommodation for eighteen first-class passengers.

Stefanie.—On Oct. 25th, there was launched from the yard of Messrs. Caird & Purdie, Barrow-in-Furness, an iron screw-steamer of the following dimensions:—245 by 35 by 17. She has been built to the highest class at Lloyd's, with water-ballast fore and aft, and all the latest improvements, to the order of Messrs. Burrell & Son, for the Adria Steamship Company. She was named the *Stefanie* by Miss Elizabeth Burrell, eldest daughter of the manging owner.

Akaroa.—On October 25th, Messrs. Osbourne, Graham & Co. launched from their shipbuilding yard at Hylton an iron sailing vessel named the *Akaroa*, built to the order of Messrs. Shaw, Savill & Co., of London, for their Australian and New Zealand trade. The dimensions of the vessel are 220 ft. by 36½ ft. beam, and 22½ ft. depth of hold, and she will register about 1,300 tons. The vessel has a full poop, containing the accommodation for the captain, officers, and a few first-class passengers; a commodious teak-house, amidships for the crew, and an open topgallont forecastle. She will be rigged as a barque, and furnished with a complete East India outfit.

Senora Cue.—On Oct. 26th, a screw-steamer was launched from the yard of Messrs, Hodgson & Sons, Cowpen Quay, Blyth. The vessel, which will be fitted with all the latest improvements, is of the following dimensions:—Length, 220 ft.; breadth, 30 ft.; depth of hold, 18 ft. 6 in. The steamer's carrying capacity is estimated at 1,400 tons, and she is classed 100 A 1 at Lloyd's. She is intended for the Spanish coasting trade, to carry first and second-class passengers, and will be fitted with engines of 130 horse-power, by the well-known firm of Messrs. Black, Hawthorn, & Co., of Gateshead. The ceremony of naming her was performed by the wife of Senor Cue, inspector to the company (Hispano Francisco), for whom the vessel has been built, who stepped forward and wished success to the *Senora Cue.*

Ganges.—On October 26th, the Peninsular and Oriental Steam Navigation Company's new steamer *Ganges* waslaunched at Barrow-in-Furness. The *Ganges*, which is built of steel, is 4,100 tons gross register, and will have engines of about 5,000-horse-power indicated. She is 390 ft. long, has 42 ft. beam, and is 35 ft. deep, and will carry 3,000 tons of cargo. The *Sutlej*, a sister ship to the *Ganges*, will be launched shortly, and both vessels will be utilized for the India, China, and Australian mail services.

Grafton.—On November 5th, the launch of the screw-steamer *Grafton*, built to the order of the Grafton Steam Shipping Company, London (Managers, Messrs. E. W. Morgan and Co.), took place at the Shipyard of Messrs. Robert Thompson & Sons, Southwick, Sunderland. She is of the following dimensions, viz.:—Length, 270 ft.; breadth, 36½ ft.; depth, 24½ ft. She has been built on the spar deck rule, under the special survey of Lloyd's to class 100 A1. She has water ballast on the improved cellular bottom principle, and has a large smokehouse aft for convenience of captain and officers, and a spacious cabin below. Engineers are accommodated under spar deck next to engine-room, and crew in forecastle under the spar deck. The vessel has four steam winches and donkey boiler, large patent gangways abreast of each hatch (four in number) for speedy discharging. Schooner rig, double topsails, and all the latest and best improvements, and engines of 180-horse power, by George Clarke, Esq., Southwick Engine Works, Sunderland. As she left the ways she was christened by Mrs. Morgan, wife of the managing owner.

Carisbrooke.—On November 5th, Messrs. W. Gray& Co. launched from their north yard, at West Hartlepool, an iron steamer, having been built to the order of Messrs. Pearson and Foster, Whitby. She has the following dimensions:—Length, 262 ft.; breadth, 34 ft. 6 in.; depth, 19 ft. 8 in. The engines are to be fitted by Messrs. Blair and Co., Limited, Stockton-on-Tees.

Coningsby.—On November 5th, Messrs. W. Gray & Co. launched from their south yard, West Hartlepool, an iron screw-steamer of the following dimensions:—Length, 262 ft.; breadth, 34 ft. 6 in.; depth, 19 ft. 8 in., to the order of Mr. A. Gladstone, of the firm of Gladstone and Cornforth, West Hartlepool, and intended for Indian and general trade, to carry 2,400 tons. She is to be fitted with engines of 160 horse-power by Messrs. T. Richardson & Son, of Hartlepool, and with all the latest improvemepts including four steam-winches and steam-steering gear and patent windlass. On leaving the ways the christening ceremony was performed by Miss Lillie Nicholson, of Bootham, York, the vessel being named the *Coningsby.*

Teutonia.—On November 5th, Messrs. Schlesinger, Davis, & Co., of Wallsend, launched a screw-steamer, named the *Teutonia*, built to the order of Messrs. Ward & Holzapfel. She is classed 100 A at Lloyd's, and is of the following dimensions:—Length between perpendiculars, 290 ft.; beam, 37 ft.; depth, 25 ft. 9 in.; deadweight capacity, 3,400 tons. She his fitted with water-ballast in double bottom, has two iron decks, topgallant forecastle for crew, long bridge amidshipswith accommodation for officers and engineers, and short poop aft with accommodation for captain and passengers. The engines of 100 horse-power nominal, 1,000 horse-power effective, will be put on board by Messrs. Thomas Clark & Co., of Elswick. The christening ceremony was performed by Mrs. Holzapfel.

On November 5th, there was launched from the yard of Messrs. J. T. Eltringham & Co., at South Shields, an iron paddle-steamer of the following dimensions:—Length, 100 ft.; breadth, 18 ft.; and depth of hold, 9 ft. 6 in. She as been built to the order of Messrs. J. Hepple & Co., of South Shields, and is intended for towing purposes. As soon as the vessel was launched the boilers were put on board at Messrs. Eltringham's Quay, and she was subsequently towed to Messrs. Hepples' works to receive her engines, which are on the side lever principle, 35 in. cylinder and 40 horse-power.

Darjiling.—On November 5th, Messrs. Oswald, Mordaunt, & Co., launched from their shipbuilding and engineering works at Southampton, an iron sailing ship of 1,950 tons register, named the *Darjiling*, built to the order of Messrs. E. Bates & Sons, of Liverpool, and of the following dimensions:—Length, 268 ft.; breadth, 29 ft. 6 in.; depth of hold, 24 ft. The ship is built with full poop and monkey forecastle, large midship house for crew, and all the latest improvements for working the ship. She is intended to class 100 A 1 at Lloyd's, and 20 years in the Liverpool Underwriters' Registry. The ceremony of naming the vessel was performed by Mrs. Mordaunt.

Popenjoy.—On November 8th, there was launched from the yard of her builders, Messrs. Raylton Dixon & Co., a steamer, built for great speed either as a first-class yacht or a quick passenger steamer, which could shortly be fitted for either purpose. She is 222 ft. long over all, by 31 ft. beam, and 16 ft. 6 in. depth of hold; has a carrying capacity of 720 tons deadweight, and can be fitted with berths for 50 or more first-class passengers, either in deckhouse, poop, or 'tween decks. Her engines, by Messrs. R. & W. Hawthorn, of Newcastle, are capable of developing 1,350 indicated horse-power, which will give her speed at sea of 13½ knots. She was christened the *Popenjoy, pro tem.*, on leaving the ways, by Miss Amy Gertrude Nixon, the youngest daughter of the builder.

Principia.—On November 8th, a screw-steamer, built to the order of Messrs. Newton Brothers, Burton-on-Trent and Hull, was launched from the yard of Palmer's Shipbuilding and Iron Company (Limited), Jarrow. The vessel is 316½ ft. long, 32 ft. in breadth, and 28 ft. deep. She will be fitted with Palmer's engines of 300 horse-power nominal, the cylinders of which will be 38 and 70 in. respectively in diameter, and the stroke of the piston 48 in. The steamer is intended for the Indian and general trades, and will be supplied with every requisite for the rapid loading and discharging of cargo. The deadweight carrying capacity of the vessel, which is built to take the highest class at Lloyd's, is 3,000 tons. The ceremony of christening was performed by Miss Lily Newton, the name of the vessel being the *Principia*.

Elemore.—On November 8th, there was launched from the yard of Messrs. S. P. Austin & Son, Wear Dockyard, Sunderland, an iron screw-steamer, built to the order of Messrs. Sharp & Co., King-street, Newcastle, of the following dimensions:—Length over all, 223 ft. 6 in.; extreme breadth, 31 ft.; depth of hold, 15 ft. 2 in.; gross tonnage, about 980; nett tonnage, about 610; constructed with short full poop and break, bridge house and topgallant forecastle, iron decks, double bottom for water ballast. She will be fitted with compound surface condensing engines by the North-Eastern Marine Engineering Company (Limited), of 110 horse-power nominal. Emerson & Walker's patent windlass, and three steam-winches. As she left the ways she was named the *Elemore* by Miss Sharp, daughter of Mr. Robert Sharp, junr.

Silver Lining.—On November 9th, a barquentine, named the *Silver Lining*, was launched from the yard of Messrs. Upham Bros., Brixham, the ceremony of christening the vessel being performed by Miss C. Upham, second daughter of the builder. Her dimensions are:—Length of keel, 125 ft.; breadth, 27 ft.; depth, 14 ft. 11 in. Her registered tonnage is 350 tons, she is of 600 tons burthen, and is the largest vessel ever built in Brixham.

Sury Wongse.—On November 19th, the iron screw-steamer *Sury Wongse* ("Glorious Son of the Sun"), built by Messrs. Wigham, Richardson, & Co., was launched at Low Water. She is built to the order of a gentleman resident in Siam. It is the first steamer owned in that country. Her dimensions are:—Length, 248 ft.; breadth, 28½ ft; depth, 17 ft. She is fitted with Emerson, Walker, & Co.'s Patent Windlass.

Claremont.—On November 21st, from the shipbuilding-yard of T. and T. W. Smith, North Shields, there was launched a screw-steamer named the *Claremont*. Her dimensions are as follows:—Length, 180 ft.; breadth, 29 ft.; and depth, 13 ft. The engines will be of 100 horse-power, and will be fitted up by Messrs. Douglas & Grant, of Kirkcaldy. Her gross tonnage is 672, and she is classed 100 A 1 at Lloyd's. The *Claremont* has been built to the order of Messrs. Fisher, Renwick, & Co., Newcastle, to be employed in the Bilbao trade, and was christened by Mrs. Renwick. The *Claremont* was towed from the Tyne to the Clyde to have her engines put in.

Magician.—On November 21st, an iron sailing ship was launched from the building-yard of Messrs. Richardson, Duck, & Co., South Stockton, of the following dimensions, viz.:—Length over all, 264 ft.; length, b.p., 244 ft.; breadth extreme, 39 ft.; depth in hold, 24 ft. 3 in.; tonnage, gross, about 1,724; tonnage, nett, 1,667. She is classed 100 A 1 at Lloyd's and 20 years Liverpool, and has been built under special survey. The vessel has a full poop for the accommodation of first-class passengers and captain and officers, a topgallant forecastle, and deck-house amidships for crew, galley, &c. The ship has been built to the order of Messrs. Nevins, Welch & Co., Liverpool. As the vessel was leaving the ways she was named the *Magician* by Miss Burgess, daughter of the Rev. A. Burgess.

Archimede.—On November 22nd, Messrs. Alex. Stephen & Son launched a very fine mail steamer of about 3,000 tons, built to the order of Messrs. I. and V. Florio & Co., of Palermo, for whom Messrs. Stephen built two similar steamers last year. The vessel, which was named *Archimede* by Mrs. Whitson, Fitzroy-place, takes the highest class in Lloyd's, and combines all the most recent improvements in construction with a fine model, and the graceful—though now somewhat uncommon—cutwater bow, and figurehead. When launched, the *Archimede* had on board her machinery, consisting of compound surface-condensing engines, with cylinders 48 in. and 90 in. diameter by 48 in. stroke, and ample boilers, suitable for a pressure of 75 lbs. She has a double bottom on bracket principle for water-ballast, and is provided with all the best appliances for working ship and cargo; while the passenger accommodation is handsome, airy, and finished in excellent taste and style.

Athabasca.—On November 22nd, Messrs. M. Pearce & Co. launched, at Stockton-on-Tees, an iron screw-steamer of the following dimensions, viz:—Length, 300 ft.; breadth, 38 ft. 6 in.; depth, 27 ft., gross register tonnage about 2,522 tons, carrying capacity of about 3,800 tons. The steamer is specially adapted for the Atlantic trade, and will be classed 100 A 1 at Lloyd's. She is built off the three-decked rule, with double bottom for water-ballast, short full poop, bridge house, t. g. forecastle, and is fitted with four steam-winches, patent windlass, steam-steering gear, &c., &c. Her engines are of 300 horse-power, by Messrs. Blair & Co., of Stockton, on the compound direct acting surface condensing principle. As she left the ways Mrs. M. Pearse christened her *Athabasca*. She will be registered at Liverpool, and has been built for Messrs. Wm. Tapscott & Co., of that city.

Ruphar.—On November 22nd, the iron screw-steamer *Ruphar*, built to the order of Messrs. Joseph Robinson & Co., North Shields, was launched from the yard of the Tyne Iron Shipbuilding Company (Limited), Willington Quay. The vessel, which has all the latest improvements, is classed 100 A 1 at Lloyd's. Her dimensions are:—Length, 287 ft.; breadth, 37 ft.; depth, 23 ft. 6 in.

Eleanor.—On November 23rd, a powerful paddle-wheel steamer, the *Eleanor*, intended for the London and North-Western Railway Company's service on the Holyhead and Greenore station, was launched by Messrs. Laird Brothers from their Birkenhead Ironworks. The *Eleanor* is the eighth vessel built by Messrs. Laird for this company, and is constructed entirely of steel manufactured at their Crewe works. Her dimensions are:—Length, 253 ft. 6 in.; beam, 30 ft.; depth in hold, 14 ft. 6 in.; with a tonnage of 1,118 tons O.M., and she will be fitted with two distinct sets of compound oscillating engines, which can be worked either together for regular work, or immediately disconnected by steam gear and worked independently for manœuvring the vessel in difficult circumstances. They are of about 2,000 indicated horse-power, and are expected to drive her at a very high speed. The passenger accommodation is contained in a full poop, entirely shut off from that part of the deck where the cattle are stowed. Fittings are provided for about 400 head of cattle, besides sheep; and special care has been devoted to the ventilation of the holds and 'tween decks, while the arrangements for the embarkation and landing of the cattle are adapted to make this as rapid and humane as possible. Protection from weather is given by a hurricane deck. The ceremony of christening was performed by Mrs. Bateson, wife of Mr. John Bateson, one of the directors of the company.

Catanian.—On November 23rd, Messrs. Edward Withy & Co. launched from Middleton Shipyard, West Hartlepool, an iron screw-steamer, built to the order of Messrs. Hugh Blaik & Co., of Leith. This vessel is No. 102 in the builders' yard, and is the fourth built for the same owners. Her principal dimensions are:—Length b.p., 285.0; beam extreme, 36.0; depth of hold to Lloyd's height of floor plates, 24.3½; and depth moulded, 25.2. She is built as a three-decked cargo boat to Lloyd's highest class, and has topgallant forecastle and long bridge-house, with water-tight ends, double bottom all fore and aft on the cellular principle, main deck of iron throughout, and upper deck of wood, four hatches and steam-winches, steam-capstan, windlass, and steam-steering gear; engines, of 200 nominal horse-power, will be supplied by Messrs. T. Richardson & Son, of Hartlepool Ironworks. As the steamer left the ways she was christened *Catanian* by Mrs. Henry Withy.

Saxon.—On November 23rd, Messrs. Turnbull & Son launched from the Whitehall Shipbuilding-yard, Whitby, an iron screw-steamer, built to the order of Messrs. Rowland & Robinson, of that port. The vessel, which was christened the *Saxon* by Mrs. Robert Wellburn, is of the following dimensions:—Length, 260 ft,; breadth, 34 ft. 6 in.; and depth of hold, 18 ft.; her deadweight carrying capacity, about 2,200 tons; engines of 140 horse-power, by Blair & Co., Stockton-on-Tees. She is intended for the Mediterranean and Black Sea Trade.

Jacob Christensen.—On November 23rd, Messrs. Raylton, Dixon, & Co. launched from their Cleveland Dockyard, a steamer named the *Jacob Christensen*, which has been built to the order of owners in Copenhagen. Her dimensions are:—270 ft. long by 34 ft. 9 in. breadth of beam, and 24 ft. 3 in. depth of hold. She will have a gross tonnage of about 1,800 tons, and a deadweight capacity of 2,500, at a draught of 22 ft. She is built on the three-deck rule, having main and other decks laid, and the latter of iron; water-ballast in large chamber in main hold forward of the engine-room, being in every respect a sister ship to the *Lesseps* (s) built by the same firm two months ago. She will be fitted with engines of 160 horse-power by Messrs. T. Richardson & Sons, of Hartlepool, and completed with first class outfit and most latest appliances for vessels of this class.

LAUNCHES.—Scotch.

Dredger No. 5.—On Oct. 24th, Messrs. H. M'Intyre & Co.

launched their shipbuilding yard at Merksworth, Paisley, the largest single dredging machine which has been constructed on the Clyde. This dredger, which has been built for the Dublin Port and Docks Board, is capable of dredging over 5,000 tons per day from a depth of 40 ft. below the surface of the water, or about double the amount guaranteed under the contract. The machinery has been constructed by Messrs. Fleming & Ferguson, Paisley, and consists of a pair of C.S.C. engines of 1,350 indicated horse-power for driving the dredging gear; auxiliary engines for hoisting and lowering bucket ladder, heaving chains by winches, warping hopper alongside; four powerful crab winches for shifting and feeding dredger when at work; steel-mounted buckets and tumblers, fitted with steel corner-pieces and bushes of same material. The ceremony of naming was performed by Miss A. Y. Fleming, of Paisley.

Cantonnais.—On Oct. 25th, Messrs. Scott & Co., Shipbuilders, Greenock, launched from their shipbuilding-yard, Cartsdyke, an iron screw-steamer, of 306 tons burthen, and engines of 60-horse power, and fitted with Emerson, Walker & Co.'s steam windlass. On leaving the ways the steamer was named the *Cantonnais*. This is the second of a fleet of six to be built by the Messrs. Scott to be used in connection with the French mail service in Cochin China, and she is similar in all respects to the *Phuoc Kien*, recently launched by them.

Stamboul.—On Oct. 26th, Messrs. A. M'Millan & Son launched from their dockyard at Dumbarton, the French mail steamship *Stamboul*, 2,200 tons and 1,700-horse-power. This steamer is to form one of the celebrated fleet of Messrs. Fraissinet & Co., Marseilles, and is intended for their Mediterranean mail, passenger, and cargo service. She has cabin passenger accommodation in the full poop for 40 passengers, and 24 passengers second-class have their saloon and rooms in the forward 'tween deck. The *Stamboul* received her name from Miss Allport, daughter of Mr. Dennison Allport, of the Royal Mail Steam Packet Company, London. The machinery is being supplied by Messrs. Denny & Co., Dumbarton. Messrs. M'Millan have another steamer yet to launch to complete their contract for four steamers tor Messrs. Fraissinet.

Saigan.—On Oct. 27th, Messrs. Caird & Co., Greenock, launched a steamer of 1,500 tons of the following dimensions:—Length on load water-line, 247 ft. 9 in.; beam (moulded), 31 ft. 6 in.; and depth (moulded), 21 ft. The steamer, which has been built for the Messageries Maritimes of Marseilles, will be supplied by the builders with engines of 250-horse power. On leaving the ways she was named the *Saigan*.

Santa-Cecilia.—On Nov. 3rd, Messrs. John Elder & Co. launched from their Fairfield Works, Govan, a steel screw steam yacht, of which the following are the principal dimensions:—Length between perpendiculars, 140 ft.; breadth, 22 ft.; depth, 12 ft. 3 in.; tonnage according to yacht measurement, 300 tons. The engines, which were fitted on board by the builders, are on the compound principle, with 18 in. high pressure and 36 in. low pressure cylinders, with 21 in. stroke, the steam being supplied at 100 lbs. pressure by one cylindrical boiler. The yacht, which has been built to the order of Lieut.-General Lord Alfred Paget, on leaving the ways, was named the *Santa-Cecilia*.

Duncrag.—On November 3rd, Messrs. Russell & Co. launched from their Port Glasgow yard a barque of the following dimensions.—Length, 200 ft.; breadth of beam, 32 ft. 6 in.; depth of hold, 19 ft. 7 in.; and of 900 tons. The new barque, which is named the *Duncrag*, has been built for Messrs. Dunn & Co., of Glasgow, and is the seventh vessel built by Messrs. Russell & Co. on identical lines.

Highland Chief.—On November 5th, there was launched from from Ramage & Ferguson's shipbuilding yard at Leith, an iron sailing barque of 900 tons nett register, for Messrs. Crane, Colvil, & Co., of Glasgow. Her dimensions are:—194 ft. by 32 ft. 6 in.; and 19 ft. 7 in. hold; and she is classed 100 A 1 in Lloyd's book. As the vessel left the ways it was named the *Highland Chief* by Miss Wear, of Felton, Northumberland.

Antonio Lopez.—On November 8th, Messrs. Denny Brothers launched from Leven Shipyard, Dumbarton, a screw-steamship for the Spanish mail service. She was named *Antonio Lopes*, by Miss Kate Risk, of Provanmill, Millerston. Her dimensions are:—Between perpendiculars, 370 ft.; breadth, moulded, 43 ft.; depth, moulded, 30 ft.; gross tonnage, about 3,430. She has been constructed of Siemens-Martin steel, under special survey of Lloyd's, and classed in their Registry 100 A 1, three-decked. She is built with a continuous cellular water-ballast bottom, with solid floors, on the system so extensively practised by Messrs. Denny, and will be fitted for 156 first-class passengers, 72 second-class, while accommodation for emigrants or troops to the number of 1,200 will be provided. The vessel will be fitted by Messrs. Denny & Co. with compound surface-condensing engines of about 4,000-horse power indicated, the cylinders being 57 and 102 in. in diameter, and length of stroke 60 in.

Odin.—On November 8th, Messrs. Lobnitz & Co. launched from their building-yard at Renfrew an iron screw-steamer named the *Odin*, and it was immediately placed in the builders' dock to receive the engines and boilers. This steamer will carry 2,000 tons cargo, and will have engines of 165 horse-power nominal of the compound surface-condensing type. The vessel will be commanded by Captain Sorensen, and the ceremony of naming the steamer was performed by his wife as the vessel moved off the ways. This steamer was launched under the Norwegian flag, and is understood to be the pioneer of a fleet of steamers which is likely to be soon afloat under the same flag.

Loch Torridon.—On November 9th, Messrs. Barclay, Curle, & Co., launched from their building-yard at Whiteinch, a four-masted sailing ship, 2,000 tons register, and of a deadweight carrying power of 3,200 tons. She is the property of the General Shipping Company, managed by Messrs. Aitken, Lilburn, & Co., and will take the berth as their December packet for Melbourne. On leaving the ways she was named the *Loch Torridon* by Mrs. Aitken, the wife of the managing owner.

Jolani.—On November 9th, the *Jolani*, an iron screw-steamer of 1,560 tons, built by Messrs. Murdoch & Murray, Port Glasgow, for Messrs. Raeburn & Verel, Glasgow, was launched. She is intended for the Eastern trade, is classed 100 A 1 at Lloyd's. She is built on the three-deck rule, with water-ballast in both holds, steam-windlass, steam-steering gear, lighthouses, &c., and will be fitted with compound surface condensing engines of about 170 horse-power nominal by Messrs. Kincaird, Donald, & Co., Greenock. The ceremony of christening was performed by Mrs. J. B. Verel, the wife of one of the managing owners.

Risveglio.—On November 10th, Messrs. H. M'Intyre & Co. launched from their shipbuilding-yard at Merksworth, Paisley, the *Risveglio*, an iron screw-steamer of 750 tons. She is built to the order of Signior Carlo Raggio, Genoa, and is intended for coasting traffic in the Mediterranean. She is classed 100 A 1 at Lloyd's, has water-ballast fore and aft, and all the latest improvements. Her machinery will be fitted on board by Messrs. Hutson & Corbett, Glasgow.

Ludgate Hill.—On November 9th, Messrs. Dobie & Co. launched from the Govan shipbuilding-yard the third of the steel twin screw-steamers, built by them for the Twin Screw Line of Liverpool, to the highest class, and measuring about 4,200 tons gross. As the steamer left the ways she was named *Ludgate Hill* by Miss Alexander, Clairmont-gardens. Owing to the continued inefficient supply of rivetting and caulking hands in the Clyde, this steamer has for a length of time been kept back in her progress towards completion of construction. She has proceeded to Clyde-villa Crane to be masted, and also to receive her machinery, which is being supplied by Messrs. James Howden & Co., engineers.

Sevilla.—On November 10th, Messrs. H. Murray & Co. launched from their Port Glasgow shipbuilding-yard, an iron screw steamer of about 800 tons deadweight capacity. This vessel, which has been built to the order of Messrs. H. Lamont & Co., Glasgow, was named *Sevilla* by Mrs. Boswell Sandeman, Ferndean, Lenzie. The *Sevilla* has been built to the highest class at Lloyd's, and is fitted with about 140 tons water-ballast in double bottom, three steam-winches, and all the latest improvements. Immediately after the launch she was towed to Glasgow to receive her engines of 100 nominal horse-power, which are being supplied by Messrs. Hutson & Corbett, Kelvinhaugh Engine Works, Glasgow. She is intended for the fruit and ore trades.

Clynder.—On November 12th, Messrs. Russell & Co. launched from their shipbuilding-yard at Cartsdyke, Greenock, a barque of 1,100 tons, built to the order of a Glasgow firm. The barque which, as she left the ways, was named the *Clynder*, is 220 ft. in length, 34½ ft. in breadth, and 21 ft. in depth. She is to be engaged in the Sydney trade.

Jean Dupuis.—On November 12th, Messrs. Scott & Co., shipbuilders, Cartsdyke, launched from their yard an iron screw-steamer of 308 tons burthen, with engines of 60 horse-power. This steamer is the third of a fleet of six to be built by the Messrs. Scott, and is similar in all respects to the *Phuoc Kien* and *Cantonnais*, already launched, and now almost ready for sea. On leaving the ways the steamer was named the *Jean Dupuis*, and was afterwards taken to Victoria Harbour to be fitted out. These steamers, as already intimated, will be used in connection with the French Mail Service in Cochin China.

Bothnia.—On November 12th, a steamer was launched from the yard of the Campbeltown Shipbuilding Company, of the following dimensions:—Length, 215 ft.; breadth, 32 ft.; depth, 15 ft.; with long quarter deck, midship house, and topgallant forecastle. The steamer has been built under special survey to class 100 A 1 at Lloyd's. She is provided with water-ballast, steam-winches, and every modern improvement for securing safety, combined with economy and rapid dispatch. The steamer has been built for the Baltic Steamship Company (Limited), of London, of which company Messrs. Weguelin, Eddowes, & Co. are the managers. As she left the ways the vessel was christened the *Bothnia* by Mrs. Eddowes, wife of one of the managers, and at once proceeded to Greenock, where she will be fitted with engines and boilers of the most modern type, by Messrs. Kincaid, Donald, & Co., of Greenock.

Catharine, DE., 453.—On November 19th, a large fishing-boat was launched from Messrs. Scott's shipbuilding-yard, Dundee. She has been built for a Broughtyferry crew, and is named the *Catharine, DE.*, 453. The following are her dimensions:—Length of keel, 53 ft.; width of beam, 16 ft. 8 in.; burthen, 37 tons. She is divided into compartments for the different kinds of fish, and has a cabin and a forecastle for the accommodation of the crew.

Neptune.—On November 23rd, a new iron twin-screw dredger of 700 tons, built and engined by Messrs. W. Simons & Co., was launched complete from their works at Renfrew. It is named *Neptune*, of Fleetwood, and is the property of the Lancashire and Yorkshire Railway Company, and is intended for the improvement of the ports in connection with their line. The *Neptune* is fitted with compound engines of 100 horse-power, and two boilers, and is the second dredger constructed by this firm for the Lancashire and Yorkshire Railway Company.

Leonora.—On November 23rd, the London and Glasgow Iron Shipbuilding and Engineering Company launched from their yard at Grovan an iron screw-steamer, built to the order of Messrs. J. T. Nickels & Co., Liverpool. The vessel, which was named the *Leonora* by Miss Goodwin, will form an addition to the fleet of vessels sailing under the flag of the Linea de Vapore Serra, Bilbao, trading between Liverpool and Havana. The *Leonora* is a well-proportioned vessel of about 2,600 tons, with the following dimensions:—Length, 345 ft.; breadth, 37 ft.; and depth, 25 ft. 9 in. She is classed 100 A 1 at Lloyd's, and also carry 1 3-3 L1.1 Bureau Veritas. Besides having extensive cargo-carrying facilities, the new ship will also be constructed to accommodate a limited number of passengers. She will be fitted by her builders with compound surface-condensing engines, of the most approved description, of 300 nominal horse-power.

Scotia.—On November 23rd, a steamer was launched from the shipbuilding-yard of Messrs. S. and H. Morton & Co., Leith. The total length of the vessel is 337 ft.; breadth of moulded beam 40 ft.; moulded depth 26 ft. 6 in.; and about 2,500 tons burthen. The vessel, which was named the *Scotia*, will be employed in the goods and emigrant Transatlantic trade between Marseilles and New York.

Omniopolis.—On November 24th, Messrs. Scott & Co. launched from their building yard at Bowling, a screw-steamer of about 300 tons, for coasting trade. The vessel, which is named the *Omniopolis*, takes the highest class in Lloyd's, being built under special survey, and under the superintendence of Mr. James Donaldson, consulting engineer. The engines, on the compound surface-condensing principle, are being supplied by Messrs. J. and T. Young, Ayr.

LAUNCH—IRISH.

Mary Armstead.—On November 8th a three-masted schooner was launched from the shipbuilding-yard of Mr. Paul Rodgers, of Carrickfergus. The vessel's dimensions are:—Length, 93 ft.; breadth 22 ft.; depth of hold, 9¾ ft. She will register under 100 tons, and carry above 200 tons, and she is classed 12 years A 1 at Lloyd's. The ceremony of christening was performed by Mrs. Cox, Ramoan Rectory, Ballycastle, who named the vessel the *Mary Armstead*. The *Mary Armstead* has been built to the order of Messrs. James Fisher & Sons, of Barrow-in-Furness. She is intended for the general coasting trade, and will be commanded by Captain Jones.

LAUNCHES.—SWEDISH.

Nanna.—On November 11th, there was launched from the yard of the Motala Company, at Lindholmen, near Gothenburg, a screw-steamer named *Nanna*, built of Motala Bessemer steel, to the order of Mr. John Giertsen and others, in Bergen, Norway. The *Nanna* is built to class at London Lloyd's, with raised quarter-deck for the Mediterranean and Baltic trade; and is of the following dimensions:—Length, 159 ft.; breadth, moulded, 24 ft. 10 in.; depth of hold, 15 ft. 6 in.; with a carrying capacity of 600 tons dead weight. She will immediately receive her engines of 50 nominal horse-power.

Polyxene.—In October last, there was launched from the shipbuilding yard at Motala a steel screw-steamer of the following dimensions:—Length over all, 85 ft.; breadth, moulded, 16 ft.; draught of water, 6 ft. The vessel was named *Polyxene*; is built to the order of Grefere Knuth, of Knuthenborg, Denmark. At a later made trial trip the engine of 25 nominal horse-power gives the ship a speed of 8·97 knots, with a coal consumption of 216 lbs., instead of 8·75, with 225 lbs., stipulated by contract.

TRIAL TRIPS.

Behera.—On October 25th, this vessel, having been fitted with new engines by Messrs. James Jack & Co., of Liverpool, ran a trial trip from the port of Alexandria. The *Behera* was built by Messrs. Samuda Brothers, of London, in 1865, and was engined by Messrs. John Penn & Son, of Greenwich; her total cost being £85,000. She had new boilers, and was completely refitted in London in 1872 by the same firms, and, till within the last twelve months, was continuously engaged in the postal service between Alexandria and Constantinople, as one of their fastest and most reliable vessels. On one occasion, when engaged on special service, she made the run from Alexandria to the Dardanelles within forty-eight hours. The new engines are constructed by Messrs. James Jack & Co., of Liverpool, and are of 300 nominal horse power, working up to 1,500 indicated horse power, they are precisely similar to those in the *Charkieh*. The results of the run on October 25th realized every expectation. The highest speed obtained was 13·4 knots with sixty-seven revolutions and 70 lb. of steam and 27 in. vacuum, the indicated horse power at this speed and pressure being over 1,500 lb., and the consumption of coal at the rate of nineteen tons per twenty-four hours.

Cachapoal.—On October 25th, the steamer *Cachapoal* took her trial trip. Her dimension are—Length, 320 ft.; beam, 40 ft.; depth of hold, 21 ft.; tonnage O,M., 2,519 tons; and fitted with a set of Messrs. Laird's direct-acting inverted compound engines, having cylinders 45 and 80 in. in diameter, with 4 ft. 6 in. stroke, supplied with steam at 75 lb. pressure from four cylindrical boilers, and calculated to develop about 2,000 horse power. She was built by Messrs. Laird Brothers, to the order of the Compania Sud Americana de Gapores. She started, at 11 a.m., from the Birkenhead dock, proceeding down Channel to Point Lynas, making a long circle to the northward, and was kept underweigh the whole day, returning to the river at 9 p.m., the engines making up to 65 revolutions, developing over 2,000 imperial horse power; speed over 14 knots made for two hours consecutively. No signs of heated bearings, and everything satisfactory; engines working smoothly.

Spartan.—On November 3rd, the screw-steamer *Spartan*, of the Union Steamship Company, made her trial trip in the Clyde. She is the largest vessel yet constructed for the Cape of Good Hope service, her dimensions being 365 ft. long, breadth, 43 ft.; depth, 32½ ft.; and gross tonnage 3,750. She will carry 150 first, 50 second, and 100 third-class passengers. The saloon is 43 ft. square and is in the centre of the vessel, and elegantly fitted up. She is one of four vessels which the company are adding to their fleet. The trial trip was eminently satisfactory.

Schaldis.—On November 7th, the trial trip took place of the *Schaldis* (s), built by Messrs. C. S. Swan & Hunter, Wallsend-on-Tyne, for the Société Anonyme Anversoise d'Armemant et de Transports Maritimes, John W. Hunter, managing director. The *Schaldis* is of the following dimensions:—Length between perpendiculars 285 ft.; breadth, 36 ft.; depth of hold, 24 ft.; is classed 100 A 1 under special survey of Lloyds, is fitted with engines 35 and 68 in. diameter and 45 in. stroke, made by the Wallsend Shipway & Engineering Co. (Limited), and will carry about 3,000 tons dead weight, and is intended for the Indian trade. She is fitted with Emerson, Walker & Co's steam-windlass. The steamer made an average speed of 11·53 knots at the measured mile, and the trial of ship and machinery was highly satisfactory.

Bretwalda.—On November 7th, the new type of cargo steamer, the *Bretwalda*, which was launched a few weeks ago from Palmer's Shipbuilding-yard at Jarrow, to the order of Messrs. Hall Brothers, had her trial trip. The vessel is 330 ft. long, 39 ft. broad; and 29½ ft. deep; and is capable of carrying 3,600 tons. Her chief feature is that she has an awning deck, being covered in from stem to stern, with an open rail, so that should the sea sweep over her, the water will find no lodgment. She is intended for the general carrying trade, but is fitted up so as to be able to carry cattle or horses on the main deck, where accommodation could be provided for 300 animals. She is fitted with every appliance for economizing labour, including steam gearing, and has ample means for ventilating and feeding the cattle, and for condensing the water for them. She has a freeboard of fully 10 ft., and the load-line has been fixed by Lloyd's. She is suited either for the American or East Indian trades. Several seafaring men were on board, in addition to a number of gentlemen, and after the engines had been tried and the compasses adjusted, she steamed away on her first voyage.

Spartan.—The Union Steamship Company's new ship *Spartan* was taken out on November 11th for her official trial at the measured mile in Stokes Bay, and attained a mean speed of over 14¾ knots. She will leave with the Cape mails on the 17th inst.

Candace.—On November 14th, the new iron auxiliary steam-yacht *Candace*, 400 tons, went out on her official trial on the Firth of Forth, with the most satisfactory results. After leaving Leith she was steamed down to the new measured mile at Gullane, a few miles west of North Berwick, and had the first trial over it that has ever been made by any vessel. With her two-bladed Bevis feathering propeller set at a pitch of 14·3 a speed of 12·245 knots was attained; but, on subsequent runs, when the pitch was altered to 15·3, the result was even better. A run was afterwards taken out to the Bass Rock, and the steaming and sea-going qualities of the vessel thoroughly tested. The *Candace* has been built for Mr. Lysaght, of Bristol, by Ramage & Ferguson, Leith, who also built the *Titania*, three years ago, for the same owner.

Ivanhoe.—On November 19th, this steamer, which was launched a few weeks ago from the shipbuilding-yard of Messrs. Murdoch & Murray, Port Glasgow, for Messrs. George Hood & Co., Glasgow, made her final trial trip. On running the measured mile at Skelmorlie, on the Firth of Clyde, she attained a high rate of speed, the engines working most satisfactorily, and reflecting great credit on Mr. William Kemp, of Govan, near Glasgow, who supplied them. This steamer is intended for the Spanish trade, and is equipped with every modern improvement. She is now loading at Glasgow for Valencia.

Supply.—There was a six hours' full-power trial in the Solent on November 23rd, of a somewhat novel craft, called the *Supply*, which is intended for Her Majesty's service as a tank vessel for the supply of water to ships on the Bermuda Station. She was built by Messrs. Laird Brothers, of Birkenhead. Her dimensions are 104 ft. between perpendiculars; 19 ft. 6 in. in extreme breadth; and 8 ft. 9½ in. in depth of hold; while her load displacement is 250 tons. She is propelled by a single screw, which is driven by a set of vertical compound engines having cylinders of 13 in. and 24 in. respectively, with a stroke of 1 ft. 3 in., and contracted to indicate 120 horse-power. The vessel is provided with powerful pumps capable of delivering from 80 to 100 tons of water per hour, and is fitted with steam fire-engine and towing appliances, which will greatly add to her usefulness on the station. At the trial, which was made by the officers of the Steam Reserve, the tanks in the fore-part of the hull were full of water, which made her draught 8 ft. 6 in. forward, and 7 ft. 2 in. aft. The mean pressure of steam in the boilers was 68½ lb., the revolutions of the engine were 162, and 119 horse-power was developed. The average speed registered by the patent log was slightly over eight knots, but the mean of six runs on the measured mile gave a speed of 7·574 knots an hour, which, in view of her trim, is satisfactory.

Steam Pinnace.—The series of trials during the last month of the steam pinnace purchased by the Government from the Herreshoff Manufacturing Company, of Bristol, Rhode Island, United States, were conducted at Sheerness in the presence of Rear-Admiral T. Brandreth, A.D.C., the new Controller of the Navy, Mr. A. J. Dunstan, chief inspector of machinery at Sheerness Dockyard, the principal officers of the Medway Steam Reserve, and the leading officials of the engineering department of Sheerness Dockyard. The Admiralty have two of these pinnaces to test, with a view to their introduction into the Navy. They are 33 ft. in extreme length, and 8 ft. 9 in. in extreme breadth, with a mean draught of 1 ft. 7 in. The displacement is about 9,000 lb. The weight of the vessel, including the machinery, is about 6,000 lb. The boiler used is Mr. Herreshoff's patent safety coil boiler, by means of which 60 lb. of steam can be got up within six or seven minutes. The engines are of the simplest design, being of the compound type. There are two cylinders connected at right angles, as this gives the engine more perfect control of the vessel as regards stopping, &c. The pinnaces are supposed to carry 1,120 lb. of coal and a small tank to hold the water required for the engines, which is comparatively little, as the engine is condensing while at work, this being accomplished by the steam passing through a pipe secured to the bottom of the boat and passing round the stern to the boiler again. The trials of the engines were very satisfactory, and the conclusion arrived at generally is that the vessels are considerably superior to the Navy pinnaces in many respects, and more especially in speed, but it is feared that they are not built strong enough to carry the torpedo gear and heavy weights required in Navy pinnaces. Mr. Herreshoff, the inventor of the pinnace, who is blind, was present at the trials.

Phosphor Bronze.—A private trial trip of this steam launch, the property of the Phosphor Bronze Co., Lim., London, took place in the Thames on Tuesday, 22nd ult. This small vessel is built entirely of phosphor bronze, and her length is only 35 ft., her beam about 6 ft., and she attained a speed of about 12½ miles per hour, which, considering her size, is a remarkable performance. The chief object of the Company in having so small a craft built was to test the rigidity of the phosphor bronze sheet and angle-pieces used in her construction prior to having boats built on a larger scale, the result having been beyond the Company's expectation as regards rigidity, absence of vibration, and the speed attained. We understand that the cost of phosphor bronze boats will not much exceed those made of steel, and the metal is not subject to corrosion like iron or steel, and retains its value. We expect to hear soon of several steam-launches, torpedo-boats, &c., being built of phosphor bronze.

Servia.—On November 17th, the *Servia* arrived in the Mersey, the largest and latest addition to the Cunard line, and one of the finest specimens of marine architecture in the world. She was launched last March from Messrs. J. & G. Thomson's yard on the Clyde, and would have been at work earlier but for the discovery of a flaw in her crank-shaft. This has been remedied by the removal of two of the cranks and the substitution of two others made of Vickers's steel, and built on to the sternmost crank, which was proved to be sound. On her trials before leaving the Clyde, it was shown that her engines indicated 10,385 horse-power. They are composed of three cylinders, one high-pressure of 72 in. diameter, and two low-pressure of 100 in., with a stroke of 6 ft. 6 in. The trials were numerous, and four of them at the measured mile gave a mean of 17·629 knots per hour. The time occupied for each mile was 3 min. 29 sec., 3 min. 23 sec., 3 min. 23 sec., and 3 min. 22 sec. The speed in each case respectively was, therefore, 17·225 knots per hour, 17·734, 17·734, and 17·823. In a run of 14 miles from the Clock Light to the Cumbrae she ran at a speed of 17·58 knots, or about 20 statute miles per hour. The highest speed at the measured mile reached a rate of 20½ statute miles per hour. The propeller made 53 revolutions with steam at 80 lb. pressure out of an available 90 lb. The trials were made in the presence of Mr. John Burns, the chairman of the Cunard Company, who also made the journey round to the Mersey to note her behaviour at sea. He was accompanied by the Marquis of Ailsa, Mr. James Dunn, of the Admiralty, and Mr. Thomas Gray, of the Board of Trade. The weather was unpleasantly rough, but the waves had comparatively little effect upon the vessel when in motion. Her great length of 530 ft., with a breadth of 52 ft., gave her unusual steadiness, and presage a smooth journey across the Atlantic. The presence of Mr. Dunn at the trials naturally directs attention to the qualities of the *Servia* as a vessel for purposes of war, supplemental to the regular Navy. It has been found by experiment that eight feet of coal will stop a shot from a 64-pounder, and that a shell will explode harmlessly in far less. The engines and boilers of the *Servia* are surrounded by water-tight compartments available for the reception of coal 10 ft. in thickness. This would give complete protection to the vital parts of the ship. Besides this, the whole length of the vessel is divided by nine water-tight bulkheads, each of which is, to all intents and purposes, a separate ship, provided the doors are closed at the time of danger. Contrary to the usual practice, the doors can in this case be closed by a lever on the main deck. The ship itself is built of steel, and has a double skin, so that were the outer plates broken the ship would still be safe. The upper, main, and lower decks are also of steel, covered with pine on the upper deck and teak below. It is held that both for ordinary safety, as well as for war purposes, steel will give greater resistance, by reason of its elasticity, than iron in the event of concussion. It offers one chance more than iron, because it will rebound where iron will crack. For transport service the *Servia* would offer exceptional advantages. She has capacity for storing coal enabling her to steam 22,290 knots without entering a port at a rate of 12 knots per hour, or 17,000 knots at a rate of 14 per hour; or, in other words, she could cruise for two or three months at a fair speed all the time. It is satisfactory to know that the Admiralty has at present a list of upwards of 200 ships, all of which have complied with the conditions of the department, so far as construction is concerned, though they may not all be as efficient for war purposes as the *Servia*. A large number of others are building at the present time in accordance with the same rules, and it is anticipated that the Admiralty will, at an early date, secure the use of the majority of them in case of necessity. There is, we believe, at present armament for 30 vessels ready for shipment at 24 hours' notice—an armament consisting, so far as ships of the character of the *Servia* are concerned, of six 64-pounders and four 40's, or ten guns with men to work them. The British mercantile marine consists now of ten-and-a-quarter million tons, four-and-a-half being steam and five-and-three-quarters sailing. The whole of the foreign tonnage amounts to eleven-and-a-half million tons, of which two-and-a-half millions are steam and nine millions sailing. These figures show very clearly the necessity, as well as the opportunity, for procuring fast-going cruisers for the defence of our mercantile marine, and the necessity will be emphasized by the fact that the agents of the French, German, and Russian Governments are following in the footsteps of the Admiralty, and collecting information as to where ships are to be bought in this country that may be turned to account as fast-going cruisers, armoured, with coal in water-tight compartments, and armed with long-range guns. It is fortunate that the requirements of the Admiralty do not interfere with the comfort or safety of the ordinary passenger nor with the cargo-carrying capacity of the vessel. The safety of the ship is indeed materially increased by compliance with these conditions; and the water-tight compartments which the Admiralty design for the storing of coal for defensive purposes are available for cargo or accommodation for the crew. The comfort of the passenger is consulted in the *Servia* by a variety of contrivances, including berths of unusual width, and by the adoption of the electric light in the saloons and smoking room, as well as the engine-room and stokehold. The electricity is generated by one of Brotherhood's three-cylinder engines, directly acting on an electro-dynamic machine, and producing 640 revolutions per minute. The electricity generated is sufficient for 117 of Swan's incandescent lights and two arc lights on deck for loading purposes.

Empire.—The new steamship *Empire*, which has been built by Messrs. R. and I. Evans & Co., to the order of Messrs. W. Thomas & Co., went on her trial trip on Thursday, November 3rd, having on board a select company of gentlemen interested in the vessel. Her dimensions are 280 ft. long, 35 ft. 8 in. in breadth by 24 ft. 7 in. depth of hold, with a gross registered tonnage of about 2,000 tons, and is built to the highest class in Lloyd's. The vessel is fitted with a pair of compound direct-acting surface-condensing engines, having cylinders 33 in. and 66 in. diameter, with a stroke of 42 in., and one steel boiler, having six furnaces, supplying steam at a working pressure of 80 lb. per square inch. Her engines, which combine all the latest improvements, have been constructed by Messrs. David Rollo & Sons, of this city, under the superintendence of Mr. Gilbert S. Goodwin. The trial was in every way a success, everything working smoothly, and with no indications of heating. At 66 revolutions per minute the vessel attained the speed of about 11 knots per hour. Although the weather was rather unfavourable, all on board expressed themselves highly satisfied with the day's run.

ERRATUM.

To the Editor of THE MARINE ENGINEER.

Alexandria, Oct. 20th, 1881.

SIR,—In your account of the trial trip of the *Charkieh*, in your number for October 1st appears a curious error which we see has also crept into other papers. We are made out as the constructors of the engines, along with Messrs. Jack & Co., Liverpool, whereas that firm alone made the engines, we acting in Egypt as their agents. Kindly insert this in your next number after receipt.—Yours truly,

ALLEN ALDERSON & Co.

P.S.—Please also note our firm is Allen Alderson—not Anderson & Co.

Reviews.

The Practical Guide to the use of Marine Steam Machinery.—By JAMES DONALDSON: Published by Chas. Wilson, of Leadenhall-street.

This is a thoroughly practical book, written to provide information in regard to the handling of engines and boilers of steam yachts and launches. It is plain and simple enough for the use of non-professional engineer yachtsmen, and yet is full of general information and hints of use to all sea-going engineers. The book opens with instruction as to the lighting up and starting of boilers and engines. Then follows good advice as to the remedying of little failings to which engines and boilers are liable, such as "knocking" and "priming." Many good precautions to prevent accident and explosions are pointed out, and the setting of valves, packing of glands, and details of management are all described with much good advice. The remaining body of the book is occupied with minute descriptions and dimensions of a great variety of engines, launches, boilers, and fittings, so that it forms a compendium of all that is good and new of that description in the market. The work will thus serve to keep the sea-going engineer up in all that is being done and invented in launch and torpedo practice, or will serve as a means of information to the yachtsman or amateur as to what is best worth his choice and attention. The illustrations are numerous, and greatly aid in giving clear examples to suit the descriptions. The book is altogether well got up, and worth reading.

Stock Requisition and Private Log-book.—By JAMES DONALDSON: Published by Chas. Wilson, Leadenhall-street, London; also in Liverpool and Glasgow.

This little memorandum-book will serve as an excellent means to induce the keeping of a regular and systematic diary or log-bog throughout a voyage. No engineer can tell what importance the dimensions of his engines and boilers, or the systematic detail of daily occurrences may prove to him. It is easy to keep a note of these facts, if suggested and done daily, and the result would prove a most interesting note-book of reference. In this little memorandum-book will be found tabulated all the details as to daily events, requisition lists, dimensions of parts, &c., that are likely to prove useful, and the very tidyness and compactness of the arrangement is in itself an overwhelming inducement to fill it up.

Correspondence.

[*It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.*—ED.]

"STATUS" OF MARINE ENGINEERS.

To the Editor of THE MARINE ENGINEER.

SIR,—The suggestions thrown out by your correspondent "Wane" in No. 30 are excellent; there yet remains the difficulty of forming a committee or responsible party who may be able to correspond with the B. O. T. in the Shipowners' Association. I have no doubt, Sir, that the majority of your subscribers are sea-going engineers, whose spare hours are devoted to their homes; who, from the nature of their occupations, have no time to take part in the management of any club. There are Sea-Going Engineers' Associations, and an excellent one at 721, Commercial Road, London, W. H. Sissons, Secretary. This has for its object the discussion of practical subjects, and aims at elevating and improving the condition of the marine engineer. This institute is, I believe, competent and sufficiently influential to bring the subject "Tonnage dues for all enclosed spaces before the B. O. T." and Shipowners' Association.

I am informed that there are clubs of marine engineers in most of our important seaports. Would it not be as well if such clubs would advertize, and bring their aims and benefits before us all?

I remember some years ago there went up the cry "Oh! what we want is a paper, a medium through which we can make known our positions and requirements; the rest will follow." The MARINE ENGINEER has been established some years, yet we are no better off than formerly. Everything has a downward tendency, notwithstanding that duties and responsibilities have increased. Having, then, such a valuable paper and medium, I hope patronized by every marine engineer and apprentice, and having also associations in different ports of the United Kingdom we only now require some competent and honest party to consolidate and amalgamate the different clubs. Considering the thousands of marine engineers afloat it seems lamentable that so many should be dependent upon the charity of such institutions as, for example, the Liverpool Seaman's Orphan Institute. I maintain that we ought to be able to support our aged, our destitute, our sick, and the orphans. I believe it possible to organize a sound insurance and annuity fund in connection with the proposed Association, one that receives the approbation and co-operation of the marine engineers in all countries. It is to be done. Who will move in it?

I am, Sir, your obedient servant,
Amalgamation.

LOSS OF LIFE AT SEA.

To the Editor of The Marine Engineer.

Sir,—In your number for October I read a letter by Mr. Thos. Cornish, on "Loss of Life at Sea," and I think a few sensible letters such as his might induce the owners of vessels to provide their ships with a better outfit of life-saving appliances.

There are hundreds of small vessels from 100 to 1000 tons trading about the English coast and to ports on the Continent, each carrying a crew of from 10 to 30 men, and yet in many of these you will find only one or two life-buoys.

I am not aware as to whether there exists in Great Britain any law as to the number of life-buoys a ship should carry, but I certainly think that every ship should carry one for each member of the crew, and, if a passenger ship, one for each passenger. I was very much impressed with the great necessity of providing life-buoys on reading an account of the loss of the s.s. *Cyprian*, of Liverpool, during the recent heavy gale, in which case it appears that each individual saved wore one; but it seems to me that even that ship was insufficiently provided, as I read of the captain giving his life-buoy to a stowaway. He, being a swimmer, undoubtedly thought that he might manage to swim ashore, but the elements overpowered him, and he (with others not provided with life-buoys) was lost.

I would further suggest that the life-buoys be kept in some convenient spot on deck, so that in case of emergency, such as sudden foundering of a ship, where there is no time to lower the boats, or the sea too rough for any boat to live, each man might help himself to one. They are often stowed away, and, when wanted, there is sometimes a difficulty in finding them: certainly a great loss of time. The use of beds, pillows, cushions, and other articles about a ship's furniture with sufficient buoyancy to sustain one or more persons, as suggested by Mr. Cornish, would be a great boon. I do not think that shipowners are much to blame in not providing the necessary means for saving life, but sea-faring men themselves for not impressing upon the owners the great necessity for such appliances. I think a few practical letters through the medium of your valuable journal would have great effect.

Yours truly,
Hy. Williamson,
Barcelona, 11th Nov., 1881. Chief Engineer, s.s. *Henry*.

ANTI-CORROSIVE AND ANTI-FOULING COMPOSITION.

To the Editor of The Marine Engineer.

Sir,—I can fully endorse the opinions expressed by your correspondents in your October number relative to the coating of ships' bottoms, viz., that generally the failure is attributable to the, one may say, disgraceful manner in which the composition is applied, which is always put down to the composition itself.

I have been in dock with steamships where actually a fire has been lit under the bottom to dry up the wet, and then the composition has been put on. I have heard the vendors of various compositions in one case explain to owners that their composition was better put on just before the ship took the water; this is when they hear the vessel is to be in the dock two or three tides only. At other times I have heard the same composition, when the ship was going to be some time in dock, especially recommended, as each coat must be thoroughly hard and dry before the next one is applied.

I have had excellent, and also very bad, results from Rahtjen's, and Blundell & Spence's compositions, both on same voyages and same vessels, and could have prophesied very nearly the results before the ship left the dry dock, and have simply formed the opinion on the state of the bottom before coating and the mode of application of the composition. I have come into dock and found the bottom, as one of your correspondents justly terms it, as foul as a half-tide rock, after being in the water only a few months, and have come into dock, after a period of twelve months, and found the bottom very little worse than when the ship took the water, and this with the same composition on, and her having run in the same waters. And, strange to say, this latter condition of bottom has sometimes formed the excuse for not thoroughly coating the bottom again.

I think myself that a great portion of injury, which is never recovered, is done in the first few months of a vessel's history, and in the manner the composition is put on before launching.

I know of a steamer that was properly coated when built, and had to go into dock some few months after launching, and, much to the astonishment of a good many, there was scarcely a particle of anti-fouling or anti-corrosive composition on bottom, and the surveyor of a registry remarked, it was a lucky accident that put her in dock, for, he said, if she had run her twelve months her bottom would have very sadly deteriorated, as even then her rivet-heads were much pitted and edge of plates damaged.

My firm belief is that the plates of a new steamer being coated over a slope surface, when the bloom of the iron is on, is partly, if not the only solution, to this early deterioration to an iron ship's bottom.

I cannot but think that if a slight coating of rust should be allowed to form, or made to form, artificially, on the plates when building, and then rubbed down with pumice-stone or some other substance, and then the red lead, or other anti-corrosive, well rubbed into the pores of the iron, that the ships' bottom would show a very different result to what they now do. And that if the anti-fouling composition was found to be worn off the anti-corrosive would be found to be pretty well intact, and form the foundation of further applications, which, if put on fairly, would preserve the ship's bottom and present a smooth surface to the water; also, lessen materially the expense of succeeding applications—instead of its being, as it invariably is, coatings—and, consequently, none of them having to be put on bare surfaces at each docking, when the ship's bottom looks like a surface of decayed cement and full of large blisters. If the above is not, partly or wholly, the reason of the deterioration, I can only assume that the iron forming the plates is not of such a good quality as the shipowner assumes it to be.

I am, Sir, yours truly,
"An Enemy to False Economy."

SEA-GOING ENGINEERS' ASSOCIATION.

To the Editor of The Marine Engineer.

Sir,—In your November part "Landsman," calling attention to the Sea-Going Engineers' Association is unable to see any improvement, owing to the craft having few ideas, from this I take it that he is well acquainted with the craft and their ideas, and is watching the progress of the association. Possibly "Landsman" has some good ideas, and, if so, I should like very much to have a personal interview with him, so that his ideas, if better than ours, might be adopted. Yet I must inform "Landsman" that competent engineers are not made in a year or two, therefore, associations of engineers will require time to accomplish the ideas the craft has got in view. In 1872 a similiar association was started, but for want of ideas the same as ours, it soon broke up. "Landsman" possibly has got some of the old ideas, and, if so, they will be of no use to us, for we have improved upon them and conducted the association to the satisfaction of the members for two-and-a-half years, and our funds have increased, so that now we are able to employ a solicitor, not so much for new ideas, but to defend its members in obtaining their just rights. Hoping, Mr. Editor, that I am not trespassing over much on your valuable space,

I am, Sir, yours truly,
William Ayre, General Secretary.
12, Hendon-road, Sunderland, Nov. 19th, 1881.

SAVING LIFE AND PROPERTY AT SEA.

To the Editor of The Marine Engineer.

Sir,—Through the medium of your valuable journal I wish to bring before the public, especially men in my own position, a few simple ideas which, though simple, may add to the means of saving, not only the lives of men going to sea, but the valuable property committed to their charge.

I would suggest that every steamship going to sea should be supplied with a set of indiarubber hose, the internal diameter of which should be the same as the outside diameter of the bilge suction pipes, made of sufficient thickness to prevent collapsing, with a clasp or flange on one end as may best suit, so that in the event of the ordinary suction pipes becoming choked they might be taken off from the pump or cut off, and the india-rubber hose attached. The hose should be left long enough to reach almost round the engine-room, as in case of the limber holes getting stopped, they can be shifted from one place to another as required; there might be a strum attached to the loose end.

I would also suggest the advisability of having discharge pipes leading from the bilge pumps to the deck, with non-return valves half way up the pipes, so that, in case of the ordinary discharge pipes becoming choked at the ship's sides, these might be used.

I have known where there was great danger in clearing the discharge valve-chest on the ship's side through the force of the water coming back, owing to the heavy rolling of the ship. This danger is greatly increased when these pipes pass through the coal-bunker, as there is more difficulty in getting at them, and in this way what is intended for the safety of the vessel may add to the cause of her being lost.

The cost of carrying out these few simple suggestions would not be much, and the benefit derived therefrom might be very great.

I remain, Mr. Editor, yours truly,
JOHN MACNAIR,
Chief Engineer, s.s. *Countess of Dublin.*
North Wall, Dublin, Nov. 21st, 1881.

LUBRICATION OF REFRIGERATORS.

ALL users of machinery are agreed as to the great importance of a careful selection of an efficient lubricant, both for running bearings and for the internal portions of their machines, such for example, as the pistons and slides of steam-engines. We are afraid also it must be added, that notwithstanding the many high and low-priced preparations offered for their acceptance, most users have had to admit the difficulty in finding such a suitable lubricant.

On a previous occasion we called the attention of our readers to the very excellent properties of "Engelbert's Lubricator," properties which, from actual experience, it has been proved to possess, and which have led to the very extended adoption we then ventured to predict for it. From the absence of impurities, its non-volatility even at high temperatures, great lubricating power, and freedom from gumming, this lubricant has for a long time been exclusively used both for the internal and external parts of engines in many of the large steamship lines, as well as in ironworks and other manufactories, and we now have to chronicle a still further and very important development in its application to the lubrication of the compression and expansion pistons and valves of air refrigerators.

The difficulties which beset the engineer in the selection of a suitable lubricant for these machines are of quite a novel character; for, in the first place, extremes of temperature, altogether unknown in ordinary machinery, are experienced, while, in addition, it is imperative that no material should be brought in contact with the air, which is capable of imparting to it even the slightest taint; otherwise, when it is delivered to the meat storage chamber an unpleasant flavour would speedily be acquired by the meat, thus at once impairing its marketable value.

In the early type of refrigerating machines, in which water was injected into the cylinder during compression, no further lubrication was attempted at this stage, nor indeed was it necessary; while during expansion, which is a dry process, recourse was had to copious supplies of glycerine. This, however, while answering the purpose, was, on account of the quantity used, expensive; glycerine being but a poor lubricant compared with "Engelbert's," although about the same in price. But in refrigerators, with surface cooling after compression, it becomes necessary to introduce a lubricating material to the compressor, and as the temperature of the air rises to as much as 300 deg. Fahr., notwithstanding the heat taken off by the water-jacket, it is important that this lubricant should not only be free from smell at ordinary temperatures, but that it should be non-volatile when heated, and also retain its lubricating properties at that high temperature.

During expansion the case is very different. The temperature of the air, and of course the cylinder also, falls to 50 deg. below zero Fahr., so that to be of any use here a lubricant must be incapable of being frozen or congealed with this degree of cold. It is also of the most vital importance that no smell should be given to the air at this stage, as it is delivered direct from the expansion cylinder to the meat storage chamber, and would retain any taint it received.

It is found that "Engelbert's" Lubricant acts efficiently under the conditions which obtain both in the compression and expansion cylinders, keeping its full lubricating qualities at both extremes of temperature, and being quite free from smell. It is, therefore, being adopted to the exclusion of glycerine, and is used, we understand, by both the Orient, and the Peninsular and Oriental Co's. for their air refrigerators.

We take this early opportunity of commenting on this important application of Messrs. Engelbert's preparation, as we are acquainted with the trouble and annoyance hitherto met with in the lubrication of the working parts of this class of machinery, and now that air refrigerators are receiving such attention, and are likely to become so widely employed, we feel it is desirable that it should be known at once that there need no longer be any difficulty in obtaining a cheap and efficient lubricating material.

TOWING HAWSERS.

THE months of October and November of 1881, will long be remembered by those interested in shipping, from the terrible gales which have visited us in rapid succession, accompanied with an unusual number of wrecks of large ships, some taking place comparatively close into our own shores, and nearly all being attended with serious loss of life. While the actual accident leading to the loss of the vessel cannot, in all cases, be directly traced to any remediable defect, it is only too true that some of the frightful disasters at sea are, without doubt, caused through the breakage of an ill-designed piece of machinery, of an insufficient hawser, or through the failure of a machine to work at the proper moment, and we regret to say that the two last reported serious losses—the one from the Inner Hebrides, and the other from the Coast of Northumberland, would appear to be of this latter class—we refer to the wreck of the sailing vessel *Culzean*, and the probable wreck of the hull of the new iron steamer *Claremont*, both of which occurrences have been fully detailed and commented on in the daily press during the last few days.

The *Culzean* was an iron clipper of 1572 tons register, which, early last week, was being towed round to the Clyde for repairs by the steam-tug *Conqueror* of 60 nominal horse-power. Three times had the vessels to seek shelter from the weather, but, beyond this, all went fairly well till they got as far as Jura. Here in a gale the tow rope broke, and the *Culzean* drifted hopelessly on to the rocks, where she became a total wreck, and her crew of eighteen hands perished.

The accident which occurred off the coast of Northumberland a day later, was of a somewhat similar character. The hull of the *Claremont* had been built on the Tyne, and was to be engined at Kirkcaldy, to which town it was being towed by the steam-tug *Sensation*. Meeting with stormy weather off Coquet Island, the hawser broke, and the vessel with all hands, the number of which is uncertain, was blown helplessly out to sea, and by this time is probably lost.

Apart from the question as to whether it is justifiable to send partially equipped ships in tow for long distances round a stormy coast at this season of the year, there is unfortunately no room for difference of opinion as to the immediate cause of the disaster in both of these cases. The cause was a deficiency in strength of the tow ropes, and from the extreme seriousness of these two events, which, however, are merely typical examples of what frequently happens, we are driven to enquire whether the rules given for guidance in determining the sizes of these hawsers do not need revision to meet the present condition of affairs.

Under Lloyds' rules, the *Culzean* would be provided with 90 fathoms of 11 in. hemp, or the same length of 3¼ in. steel-wire hawser, each of which would have a breaking strain *when new* of 26 tons. In very smooth water, under ordinary circumstances, the mean pull on the hawser would probably not exceed 6 tons, or about one-fourth of the breaking load; but in a storm, or even in a moderate sea, it is evident that the case is entirely changed, and that the strain on the rope might be increased, not indefinitely it is true, but to an extent controlled only by the momentum and inertia of the vessels; and it is extremely improbable that, in the present case, with a tug the size of the *Conqueror*, a factor of safety of four times would at all represent the allowance necessary to cover the increase from rolling and pitching, as indeed was proved by the result.

Again, for steam-vessels, the strengths given by Lloyds are even more out of proportion than for sailing-ships. A steamer of 2,400 tons is required to be furnished with 100 fathoms of 12-inch hemp or 4-inch steel-wire hawser, either of them being equal to a breaking strain of 33 tons *when new*. But as a steam-vessel generally requires to use her ropes in the event of a breakdown of her machinery at sea, in which case she is not towed by a light tug but by another steam-propelled vessel as powerful, or, perhaps, more powerful than herself, while the sailing-vessel is more likely to be towed in calm weather, or on entering a port or harbour, it is surely obvious that the steamer should be provided with hawsers at least double the strength of those necessary for a sailing-vessel of equal size.

Within the limits of an article such as this we can do little more than direct the attention of shipowners and engineers to these discrepancies, which, we fear, can only be rectified by the force of opinion. It is, however, most noteworthy that, among others, the Peninsular and Oriental Steam Navigation Company has already made a very considerable deviation in the direction we advocate, and is fitting its vessels with Messrs. Bullivant and Co.'s steel-wire hawsers equal to fully double the breaking-strain laid down by Lloyds' rules, but yet weighing no more than the hemp-ropes required by these rules. We hope that, after attention has been once directed to this important matter, it will not be long before the necessary change is accomplished, so as to ensure to our vessels a greater safety when being towed than at present seems to exist.

HYDRAULIC MACHINERY ON BOARD A SHIP.

FOR some time past attention has been given by mechanical engineers to improvements in the methods of loading and unloading and other work on board ocean-going steamers, and especially those which carry both passengers and freight. The *Quetta*, which sailed for Calcutta from London recently, and is the last-built of the British India Line, offers a striking example of some of these improvements. Her length is 380 ft., breadth 40 ft., depth of hold 29 ft., and gross tonnage 3,302 tons, and she is distinguished from all other vessels by a new system of hydraulic machinery applied for the first time to ocean-going steamers for the purpose of steering the ship, heaving the anchor, and taking on board and discharging the cargo. All these functions are performed by a hydraulic system ramifying throughout the ship, and worked by pumping engines of 100-horse power in the engine-room. The various pipes spreading fore and aft, and even up the masts, and serving to transmit the force originated by steam power in the centre of the vessel, might be compared to the arteries of the human frame circulating the blood pumped into them by the heart.

The machinery may generally be described as follows:—A pair of compound condensing engines of 100 indicated horse-power pump water (or in winter non-freezing fluid) from a tank into a steam accumulator. The pumping engines are started and stopped by the falling or rising of the steam piston in the accumulator; and since the piston falls when the hydraulic power is being utilized and rises to its former level when the power is not in use, it follows that the apparatus is perfectly automatic. Once started, it does not require the supervision of an engineer, and it maintains a steady pressure of 700lb. per square inch in the hydraulic mains or pressure pipes. These are carried up from the engine-room fore and aft of the ship. Alongside the pressure mains a similar return main is laid, which discharges into the tank. From the pressure mains branches are connected to the various hydraulic machines. In order to admit the pressure to anyone of these machines nothing is required except a turn with an iron key. After having done its work, the water is discharged into the return mains, being thus used over and over again.

Next may be stated in detail the ship's gear worked by this hydraulic system. At the forecastle is placed a hydraulic capstan of 15 tons power, which is driven by four pendulous hydraulic cylinders, collectively of 50-horse power, acting upon a revolving eccentric, the shaft of which is directly connected to the windlass for heaving the anchor, while the capstan above is available for warping the ship. A similar but less powerful capstan is placed at the other extreme end of the mains on the poop.

The ship is steered, not by means of the usual wheel aft, but from the bridge amidships, by a simple wooden tiller similar to that of a small yacht. A wheel, indeed, was originally added to humour the prejudices of the crew, but after the experience of a voyage, it has been stowed away as superfluous. By moving the tiller, a slide-valve is opened, which is in connexion with the hydraulic rams and cylinders aft. When the valve is opened to either port or starboard cylinder, a corresponding movement of the rams and rudder takes place, strictly controlled, however, by mechanism which prevents the helm from running away from the steersman. The rudder itself is connected with the rams in such a way that the latter obtain an increasing leverage as the rudder is being put hard over, when this leverage is, of course, most needed.

A hydraulic cylinder with a similar arrangement of valve and automatic controlling levers is applied to the marine engines, by which they can be reversed or stopped in three seconds by a single reversing lever. The water-tight door of the shaft tunnel is also opened and closed by a hydraulic cylinder, the valve of which is near the deck, so that in the event of accident this door can be instantly closed. In the stoke-hole close by is fixed a hydraulic hoist for lifting the ashes.

As has been said, however, the most valuable application of the *Quetta's* hydraulic machinery is to the loading and unloading of the cargo. Notwithstanding the great advance in speed which has been attained during the last quarter of a century by improvements in ships' build and engines, it is somewhat remarkable that the method of loading and discharging cargo speedily has received little or no attention. The prevailing arrangement for effecting this purpose has, for the last twenty-five years, been nothing more nor less than the old hand-worked winch, with its train of cog-gearing, but with two steam engines applied to dispense with manual labour. These steam-winches are placed at the different hatches, involving, in our longest steamers, a length of copper steam piping of 600ft. The disadvantages of such a system are obvious, as many can testify who have made the passage to Calcutta and who have tried to sleep in their berths under the noise and rattle of the many-cog wheels and quick-running engines working at night at the various ports on the way. In the *Quetta* not only is this noise and vibration obviated but, at the same time, a higher speed of lifting the cargo is obtained, which, of course, means a saving of labour and a quicker voyage. As an instance of this, it may be mentioned that at Colombo, in the course of the single voyage which the *Quetta* has already made to Calcutta and back, 1,250 tons of rice were discharged in 10 hours. Besides these advantages, others are obtained, such as economy of fuel by the adoption of compound pumping engines and the absence of long steam-pipes which condense the steam; and, lastly, following upon the absence of noise and friction, a great reduction of wear and tear in deck machinery.

The hydraulic lift is well known and largely adopted in docks, but has never before been successfully applied to ocean-going steamers. On the *Quetta's* deck there are four hatches. Those at the extreme ends fore and aft are fitted with single hydraulic lifts, the two main hatches having double hydraulic lifts. Each of these lifts is capable of raising a ton-and-a-half through a height of 70ft. at a speed of 5ft. per second. The lifts consist of hydraulic rams, fitted into cylinders, and working through stuffing-boxes. Each ram is connected to three chain pulleys, while the other three are carried by the cylinder base-plate. A foot of rise in the ram raises the load 6 ft. The water is admitted to the cylinder by a slide-valve worked by a single-lever, whereupon the load is lifted; while, by reversing the lever, the water is allowed to escape and the load to descend. An ingenious arrangement, which we have no space to describe, prevents the load from running from one extremity to the other, through the unskilfulness of the driver, and thus risking damage to the cargo. A wholly inexperienced man can thus work the apparatus without any danger. The hoists will discharge cargo at the highest speed of 5ft. per second and be brought to a state of rest automatically at any position required.

It is not claimed that the hydraulic system, as applied to ships' fittings, is absolutely new, but it has not before been successfully and completely applied to ocean-going steamers. The same engineer who fitted the *Quetta* applied, 12 years ago, hydraulic steering-gear and reversing-gear to the Birkenhead ferry boats. The Peninsular and Oriental Company's steamer *Poonah* was also fitted by him with hydraulic steering-gear, which, owing to the want of sufficient controlling power, was not a success. Three years ago the *Kosmos*, built by Messrs. Denny, to ply on the River Plate, was fitted by the same engineer as completely with hydraulic machinery as the *Quetta*; but, as a comparatively small river steamer, it is not to be considered on the same footing as the larger ship.

To summarize the advantages of the *Quetta's* hydraulic machinery a pair of engines in one place do, with no noise and half the consumption of fuel, the work usually performed by, perhaps, a dozen donkey engines; while about £30 or £40 a voyage is saved in wear and tear. The increase of speed obtained in loading and discharging cargo practically insures a quicker voyage. The rapidly-working machinery necessitates double gangs of men in the hold; but, though the hands are more numerous, they are paid for a shorter time; and the cost of labour per ton of cargo is thus less than usual. The prime outlay is considerably greater than under the ordinary system; but it is calculated that in at least three years the extra expense will have been saved.

The *Quetta* was built at Dumbarton, by Messrs. Denny Brothers; the hydraulic machinery was designed and carried out by Mr. Andrew B. Brown, Mem. Inst. M. E. Edin. It may be mentioned that three more ships of the British India Line are to be constructed on a similar pattern.

TORPEDO BOAT FOR THE DANISH GOVERNMENT.

MESSRS. THORNYCROFT & CO., of Chiswick, have lately completed a large torpedo boat for the Danish Government which differs in many respects from the usual type of first-class boat built by that firm, not only in her size, which is probably greater than that of any torpedo boat afloat, but in the nature and extent of her armament, and in the arrangement of the accommodation on board of her. The boat in question is 110 ft. long by 12 ft. beam, and has a displacement of 55 tons, with all her weights on board and ready for action. This displacement is far in excess of that of the English first-class boats, which amounts to only 33 tons. It may be noticed that the beam of the boat is somewhat less than is usual in the later types of torpedo boat. The reason of this is that 12 ft. is the largest beam that would allow of the boat passing under the bridges on the Danish railways, the intention of the Danish Government being to carry all boats of this class on specially designed trucks from one part of the coast to another, so that, although an enemy might know the exact number of torpedo boats possessed by the Danes, he could not know their whereabouts, and might be attacked from any part of the coast.

Her armament consists of four Whitehead torpedoes of the largest size—viz., 19 ft. in length by 15 in. diameter, which will be ejected through two discharging tubes of the Whitehead pattern fixed in her bows. In this type of ejecting apparatus the torpedo itself takes the place of the piston in the usual impulse gear, and the air, at a pressure of about 1½ atmospheres, is admitted behind the torpedo, which it ejects at a speed of something like 30 knots per hour. When the boat is ready for action, two of these torpedoes will be carried in the ejecting tubes and two in the loading shoots in the torpedo room immediately to the rear of the tubes. After the first two are discharged, the second two can be put in the tubes without the men exposing themselves by coming on deck. In both these respects the Danish boat differs from the English first-class boats, which only carry three torpedoes of the smaller size—viz., 14 ft. in length by 14 in. diameter, and carry one of them partially protected in the revolving ejecting tube on the forward deck, and the remaining two entirely exposed in transporting carriages amidships. The English boats have the advantage of being able to discharge their torpedoes on the broadside while passing an enemy at full speed, while the Danish boat will have to come up bows on. The target, however, exposed to the fire of the Nordenfelt and other machine guns will be much greater in the case of the English boats than of the Danish. The charge in the 19 ft. torpedoes of the Danish boat is 80 lb. of gun-cotton, and they are capable of going a distance of 1,000 yards at a speed of from 18 to 19 knots. On the top of the conning-tower is fixed a Hotchkiss revolving cannon of 1½ in. diameter of bore.

The hull is made of steel plates and angle bars, carefully galvanized throughout, and is divided, as is usual in boats of Messrs. Thornycroft's construction, into a large number of compartments by means of bulkheads and half bulkheads. All these compartments may be drained on ordinary occasions by means of sluice-valves into a large tank in the boiler-room, from which the water is pumped overboard by means of the bilge-pumps in the engine-room. But to provide for extraordinary leakages, five large steam ejectors, each capable of discharging 20 tons of water per hour, are disposed in the various parts of the vessel, so that on a leak occurring in any compartment the steam may be at once turned on by the men stationed in that compartment, and the leakage kept down while the hole is being plugged to allow of the complete ejection of the water.

The engines are of the usual compound condensing type, the sides and ends of the cylinders being carefully steam jacketed and lagged, so as to insure the utmost economy in the working of the engines, one of the conditions of the contract being that the boat should carry sufficient coal to run a distance of 1,000 miles at a speed of about 10 knots. The boiler is of the locomotive type and is fitted with appliances for protecting the stokers in the event of a tube bursting, and for at once extinguishing the fire in case of necessity. The coal bunkers are capable of holding 10 tons of coal, which quantity was found sufficient on trial to propel the boat 1,200 miles at a speed of 11 knots.

The speed trials previous to the reception of the vessel took place on the Thames on October 29th, the Danish Government being represented by Captain Johnke, Chief of the Danish Naval Torpedo Service; Captain Neilsen, Chief Constructor of the Danish Navy; Lieutenant Rasmussen, Assistant Constructor to the Danish Navy, and other officers. The contractors were represented by Mr. John Donaldson, assisted by Mr. Barnaby and Mr. Brown. Captain Eckermann, Chief of the Swedish Torpedo Service, was also on board during the trial.

The trial stipulated for in the contract was that the boat should attain a speed of 18 knots on a run of three hours' duration, with a load of 12½ tons on board, to represent the armament and stores when ready for service, and this speed was to be ascertained by running the boat for three hours and taking the number of revolutions of the engines for that period, and subsequently by running her six times over the measured mile with half the quantity of coal necessary for the three hours' run deducted from the 12½ tons, so that the boat on the mile runs might, in regard to weight, be in the average condition she would be in during the three hours' run. But as this involved the necessity of running the boat on two separate days, and as it was considered desirable to complete the trials in one day, the expedient of taking three runs on the measured mile before the three hours' run, and three runs afterwards, was adopted.

The mean speed during the first three runs was found to be 20·366 knots, and on the second three runs 21·127 knots, giving a mean speed of 20·746 knots. The number of revolutions required to do a knot in still water was found to be 1,175, and the total number of revolutions during the three hours' run 70,195, which gives a speed of 19·91 knots, or practically 20 knots per hour—that is to say, two knots above the contract speed—a result which was considered highly satisfactory by all parties concerned.

NEW TORPEDO BOATS AND GUNS.—An interesting trial of a new torpedo vessel, the invention of Mr. John Ericsson, took place in New York Harbour on November 11th. The boat is 135 ft. long, 11 ft. deep, and 12 ft. wide. It is strongly armoured, of 1,000 horse-power, and has realized a speed of 16 knots. Its gun rests on the keelson, with the muzzle submerged six feet, and discharges the projectile directly into the water. In previous experiments a charge of 12 lbs. of coarse powder was used to discharge a dummy torpedo, which was projected a distance of 600 yards. In actual warfare the explosive charge is intended to be 340 lbs. of dynamite. Mr. Ericsson states he has made 52 trials of the weapon, each one of which has proved successful. He claims especial merit for it on the ground of its being easily managed, immediately repaired if damaged in action, and also for the accuracy with which the projectile travels towards a given object. At the same time a model of the Lyman Haskell Accelerating Multi-charge Gun was exhibited. Its novelty consists in having four charges disposed in chambers at intervals along the bore, these being successively ignited as the shot passes along the barrel, with the result that the velocity is enormously increased. A 10-inch Haskell is supposed to be equal in destructive effect to an 80-ton Armstrong gun.

TORPEDO BOATS.—The two improved first-class torpedo boats which Messrs. Yarrow & Co. lately built for the Argentine Government reached Buenos Ayres in perfect safety. These were rigged for sailing, and were found to answer very well under canvas. One was navigated direct from London across the Atlantic without being accompanied by any convoy, while the other steamed first to Fiume to have her torpedo gear fitted on board at Mr. Whitehead's works. This is the first occasion on which a torpedo boat has crossed the Atlantic, the result proving that craft of the kind can be built combining exceptional speed and rapidity of movement with thorough seaworthiness and capability of steaming long distances. The two Austrian boats completed by the same firm, which, it may be remembered, realized a speed of 22 knots, have successfully steamed from Poplar to Pola. Messrs. Yarrow have also despatched ten of the same class of torpedo boats, known as the "Batoum" class, to the Mediterranean without their being indebted to anything but their own resources, thereby proving that they can be navigated long distances in case of need. The firm are at present engaged in building similar boats for the Dutch, Italian, Portuguese, Argentine and Brazilian Governments.

Recent Applications for Patents connected with Marine Engineering, Ship Construction, and Mechanical Appliances for use in Ships, from 20th October to 20th November, 1881.

4605 J. Tinker and others. Steam boilers.
4625 G. W. Clarke. Steam boiler furnaces.
4629 J. G. Stidder. Gland stuffing boxes.

EDITORIAL NOTES.

NEW competitors to England, in the shipping carrying trade, have suddenly appeared. Of all people in the world it is the Chinese who are thus daring to rival the mistress of the seas in her commercial pursuits. The steamer *Meifoo* has just arrived in the Thames from Shanghai, and is the first of a regular line of steamers under the Chinese flag. It is proposed in China to establish a regular line of steamers between London and China, to carry on a direct import and export trade. The proposed association will commence with a capital of £150,000, and will include as members, some of the highest and wealthiest Chinese capitalists and merchants. The Association is to be under Chinese management, and two managers Lun-shi-ting and Laing-sing-un came over in the *Meifoo* as passengers. They propose to establish their head-quarters in London, and they hope to do a thriving trade. The *Meifoo* brought over a cargo of tea, and is said to be the first vessel under a Chinese flag to deliver cargo in the London Docks. The *Meifoo* was formerly the iron barque *Benclutha,* which was stranded on the Shantung promontory, but was afterwards got off in 1879.

ENGLISH ship-owners, however, do not seem to be relaxing in their efforts to keep pace with any amount of carrying demand that may be made upon them. The Clyde building trade continues to be brisker than was ever known before, and the annual turn out for this year promises to be at least 50,000 tons in excess of the year 1874, which had been hitherto the largest known. 32,366 tons were launched in the month of November, the largest monthly output ever known, nor do the orders in hand exhibit any flagging tendency for the new year. Amongst many new contracts placed with the Clyde builders, we may mention five new steamers ordered for Messrs. Donald Currie & Co.'s "Castle Line" to the Cape. Three of them are to be of fully 4,000 tons each, and the other two of about 3,000 tons. Messrs. Money Wigram & Sons, Limited, have also arranged for the building on the Clyde and on the Tees of three steamers of about 4,000 tons each for their Australian service. All this points out without a shadow of doubt that we are at last through the dull days, and entering another decade of prosperity which promises as each former wave has done, to still surpass in the maximum of trade and national prosperity that it will reach any former cycle of inflation This will prove a triumphant reply to the dismal augurs of England's decadence which have been latterly so prevalent.

WE have every sympathy with Admiral J. E. Commerell in his endeavour to impress the importance of a jury rudder being carried as a complement to all mercantile vessels and to men of war. Our Government Boards are proverbially hard to move, but we are surprised that not more attention has been paid to such a subject by the many enterprising owners of ocean steamers. It is well known that nothing is a more sure cause of foundering at sea than the loss of steering power. If we may judge by analogy from the number of vessels that creep into port more or less damaged about their steering gear, there must be many vessels lost in mid ocean from this cause that are never heard of. The *Bacchante*, some little time ago, was in a situation of much danger, and was unavoidably separated from her squadron through an accident to her steering gear. The very modern improvements of steam steering gear, and complex mechanical fittings, will all serve to render the chances of fouling and accident more numerous. The very material, iron, in which our ships are now mostly built serves to render any temporary repairs more difficult and impossible of execution without docking and special appliances. We think it would be an exceedingly easy matter to provide for any contingencies of fouling or breaking to the steering gear under the two following heads:—First, that on any rudder being fouled it should be arranged so as readily to unship and be either hoisted on board or got rid of. And, second, that each vessel should be provided with special appliances to enable a jury rudder to be promptly shipped, capable of taking the ship into port.

WE seem to be as far off as ever in the matter of a suitable armament for our Navy. Nearly twelve months ago some distinct statements were made in Parliament as to new guns being in preparation for the Navy on the breechloading system. We have heard nothing, however, as yet as to any trials of their efficiency, and of course it would, or ought to be, impossible for the Admiralty to accept such new guns from the War Department without such thorough test. We are inclined to believe that there is some hitch about them. As it is generally understood that the famous 43-ton gun, with which Woolich was to astonish the world, has not created the stir expected of it, and was thus something of a failure, so it is easy to imagine that Woolwich has again failed as gun manufacturers. It is notorious that Italy is having most powerful and satisfactory weapons manufactured by private firms in England, and it is thus absurd for us, as taxpayers, to see the finest ordnance made on our own shores for foreign governments, whilst our own War Department is still bungling about in the difficulties of experiment and failure.

THE submarine telegraph companies are powerfully agitating, with very good cause, to obtain international protection for their cables. The evident interest of all parties owning shipping property would in itself have appeared sufficient to have deterred any of their servants from carelessly damaging any submarine cable. Many of the accidents, however, arise from the careless anchoring of vessels too near to the line of cable, or from the fouling of repairing vessels by ships or steamers allowing their course to run unnecessarily close to them. In the case of individual fishermen, too, who wilfully cast their nets across cables or allow themselves and their nets to float foul of repairing vessels, their seems no other means of restriction except by police measures. The companies thus hope to get international police regulations carried into effect against those wilfully damaging cables or buoys used whilst repairing the same. We think it probable that this very reasonable request will be granted, and we shall hope to see it bear fruit it in the less frequent disturbance of the means of telegraphic communication, which has now become so important to all commercial industries.

SHIPBUILDING ON THE CLYDE.—The year 1881 has been one of remarkable activity in the shipbuilding industry of the Clyde. Altogether 261 vessels have been launched, with an aggregate measurement of 341,022 tons. Last year, which showed the largest total of any year except 1874, the tonnage reached 248,000, or about 90,000 under the present figures; and the returns for 1874 are exceeded by between 70,000 and 80,000 tons. Notwithstanding this large output the prospects are of the brightest description, as it is understood shipbuilders have a larger number of contracts on hand than they had at the beginning of the present year, while several yards which have been closed for some years are about to be reoccupied. An analysis of returns supplied by the various builders shows that there has been a large and general increase in the size of the vessels launched. This, indeed, is the chief feature of the year's work. An unprecedentedly large number of the vessels launched have been built of steel. In 1879 the figures for steel work were 18,000; in 1880, 42,000; and this year, 66,609 tons; and it is worthy of note that a number of the largest vessels have been constructed of the new material. The increase is pretty fairly spread over all the Clyde firms. Messrs. J. & G. Thomson head the list with 27,100 tons, and Messrs. John Elder & Co. come next with 26,575 tons. The following is a general abstract of the number of vessels completed during the year 1881:—J. & G. Thomson, 7 vessels; John Elder & Co., 9; A. Stephen & Sons, 10; Dobie & Co., 7; Wm. Dennie & Bros., 8; London and Glasgow Shipbuilding Co., 7; Russel & Co., 11; A. M'Millan & Sons, 6; Barclay, Curle & Co., 9; Caird & Co., 4; Chas. Connell & Co., 5; A. & J. Inglis, 6; D. & W. Henderson & Co., 6; Lobnitz & Co., 8; H. M'Intyre & Co., 14; James Steel & Co., 12; Robert Napier & Sons, 3; Robert Duncan & Co., 14; Aitken & Mansel, 4; Cunliffe & Dunlop, 14; John Reid & Co., 7, Robert Steele & Co., 5; Wm. Simons & Co., 6; H. Murray & Co., 7; Murdoch & Murray, 6; Blackwood & Gordon, 12; Napier, Shanks & Bell, 4; The Campbeltown Company, 5; Robert Chalmers, jun., 2; Wm. Hamilton & Co., 1; Wm. Burrell & Co., 1; John Fullarton & Co., 4; Campbell & Co., 4; T. B. Seath & Co., 10; Hanna, Donald & Wilson, 11; Barr & Shearer, 2; Scott & Co., Bowling, 3; Wm. Fyfe, Fairlie, 5; J. Macadam, 2—total 261. For the sake of comparison, we subjoin the tonnage launched on the river for the past 23 years:—

Year.	Tonnage.
1881	341,022
1880	248,656
1879	174,780
1878	222,353
1877	169,710
1876	174,824
1875	211,824
1874	262,430
1873	232,926
1872	230,347
1871	196,229
1870	180,401
1869	192,310
1868	169,571
1867	108,024
1866	124,513
1865	153,932
1864	178,505
1863	123,262
1862	69,967
1861	66,801
1860	47,833
1859	35,709

AN IMPROVED METHOD OF STOWING AND DISCHARGING TORPEDOES FROM TORPEDO BOATS OR OTHER VESSELS.

THE idea of an offensive attack by means of a boat specially constructed to carry an explosive machine, which would severely damage and probably wreck the vessel attacked, has existed for more than a century.

This was in the first instance an American invention, brought out by Captain David Bushnell, of Connecticut, in 1775. His boat held only one person, and contained an air-tight chamber, with a sufficient quantity of air to support him for thirty minutes. Beneath this chamber was a water-tight chamber, fitted with means of letting in water or pumping out again, by the appliance of a force pump, for the purpose of sinking or raising the vessel at will. When at a proper depth below the surface, the boat was propelled under the bottom of the vessel to be attacked by an oar led to air chamber, and by means of forcing, with an arrangement also from the air chamber, a screw into the bottom of the vessel, a torpedo regulated by clockwork would be left attached. In 1801, various experiments were made at Brest for the French Government, by the celebrated Fulton, the boat he used being a diving one, propelled by a scull worked by hand-gearing. He made many useful experiments, and at one time blew up a small vessel. His plans and ideas were laid before our Government in 1804, but were cast aside as impracticable. Fulton, in the course of his experiments, developed the idea of the torpedo launch of the present day. He made a model of a 300 ton wooden vessel to have sides 6 ft. thick, for the purpose of rendering them cannon proof, and decks 6 ft. thick, which were to be musket proof. She was to be propelled by hand by a scull-wheel, and to travel at a speed then considered a high one.

The torpedoes were fixed on the ends of spars 56 ft. long, stayed by guys from the mast-head. From Fulton's time till the Crimean war, the torpedo question stood comparatively still; then, however, it only revived partially in the shape of stationary torpedoes or submarine mines, which were employed by the Russians for the defence of Sebastopol and Cronstadt.

Again during the Civil war in America, torpedo boats were resorted to, and some vessels were blown up by their means. At the same time, for want of proper arrangement and management, they were in some instances, blown up as well as the vessel they attacked. At the close of the war, both sides were busy in preparing special spar torpedo boats. Since then, vast strides have been made towards perfecting the efficiency of the torpedo boat in the most destructive method of attack. To carry this out, the speed of torpedo boats has increased from time to time to nearly double that to be obtained from them a few years ago. Owing to the immensely increased destructive power of naval guns since the time of Fulton, the idea of building small vessels shot-proof has been abandoned; the torpedo boat of the present day, trusting to her speed and the small mark she shows as a target, to escape scatheless. Fulton's idea of the method of attack by means of spar torpedos still meets with a certain amount of favour and attention. At the same time, various other methods of stowing and discharging torpedos, have been proposed or tried with varying success.

In perfecting the stowage and discharge of torpedos, many things have to be considered. Torpedos are bulky and heavy machines to move about in the confined limits of a steam launch, weighing as they do, from ¾ of a ton to a ton each. On this account they should be stowed as near the point of discharge as possible. At the same time, the point of discharge with the arrangements for discharging should be hidden from the view of the enemy, together with the knowledge of the direction in which the torpedo is aimed.

Again, as the torpedos at present in use are supposed to strike an armour-clad below her armour-belt, the aim in discharging is to drive it on an object six or seven feet below the surface of the water. To accomplish this, various methods have been tried to supersede the spar system.

In some instances, torpedos are discharged from guns or tubes carried on the deck of the boat. Although accurate aim may be taken, the torpedo in entering the water generally meets with obstacles which prevents it from reaching its intended mark. The side crest of a wave will sometimes catch the point of the torpedo as it is breaking the surface, and throw it entirely out of the course it is intended to take. The small angle of entrance of the torpedo obtainable from the deck of a launch when discharged from these tubes, frequently causes the missile to skim on the surface, by which course it wastes its force on the thickest portion of the armour-belt of a man-of-war.

Another method in use, is that for discharging torpedoes from channels cut at an angle to the deck, and running down by the side of the stem. By this method the torpedo is discharged under the surface of the water, but this is done at an angle which would necessitate the launch being very near the vessel to be attacked; at the same time, the operations for discharging must be carried on in the full view of the enemy. Other complicated arrangements have been made for discharging torpedoes through holes or tubes through the bow of larger vessels, as well as ordinary torpedo launches, but a lot of time and manipulation is necessary to effect a discharge.

The Figs. on our illustrated sheet, show a design by Mr. J. E. Atkinson, Member of the Institution of Naval Architects, specially prepared to meet all the points set forth in a most simple and highly practicable manner.

The chief feature of the design, will be seen to consist of a trunk or well space through the middle of the torpedo boat situated at the fore side of the boiler space, and far enough from the bow to escape being injured by a collision. At the bottom of the well, a discharging trunk is fitted, capable of being momentarily placed in an oblique position, enabling the torpedo to be discharged in a direct line with the keel either forward or aft. The torpedoes to the number of 3, 4, 5 or 6, according to the depth of the boat, may be stowed one above the other, on hinged brackets in the trunk or well, and lowered in position for discharging in rapid succession. All observations are taken from the small conning tower at the fore end of the trunk or well from the crew space on the deck below, and every arrangement for discharging either ahead or astern can be made without the slightest sign that any such operation is in course of preparation, as not a single hand is required on deck.

Fig. 1 shows a longitudinal section of the well with the torpedoes (*a*, *a*, *a*) stowed, and the discharging trunk (*b*,) closed. The points (*c*, *c*,) are those on which the discharge trunk (*b*) is pivoted, these can be fixed or thrown out of gear at each end as required, at will, admitting of the trunk being lowered by means of the gearing (*d*, *d*) rapidly into the required oblique position either for a forward or after discharge. At the fore end of crew space, there is a water-tight collision bulkhead, *e*; this crew space occupies not only the space at the fore end of the trunk or well, but the wings or side-spaces as far aft as the boiler-room bulkhead.

The tubes (*f*, *f*) at each end of the trunk or well, are impulse tubes, through which pressure is brought on the torpedo by steam or air, to give it the necessary impetus for an effective discharge, and (*g*) is the conning tower, from which all observations are taken under cover.

Fig 2 shows longitudinal section of well, with the discharging trunk lowered for firing the torpedo ahead; the dotted lines show the discharging trunk lowered for firing the torpedo astern. Fig 3 shows a cross section through the well with the carrier (*h*) in position after lowering torpedo into discharging trunk. The dotted lines show the carrier raised for lowering the other torpedoes when required. The lid (*i*) is arranged to close tight whilst the torpedo is being discharged, and raised again, as in Fig 4, when the trunk is replaced after discharging, so as to admit of placing another torpedo in position.

In Fig 4 the hinged brackets (*k*, *k*) are shown; these support the torpedoes in position till they are required for use, when they are lifted by means of an attachment from the framework (*l*) the hinged brackets (*k*, *k*) are then swung aside, and the torpedo placed on the carrier (*h*) to be lowered in position for discharging. Figs 5 and 6 show the torpedo boat discharging ahead and astern respectively, and the chief divisions of after cabin, engine and boiler space, and crew space. The discharging trunk (*b*) fits the form of the bottom of the boat perfectly when in place, and thus keeps up the continuity of force and speed. The arrangements and provisions made in this design will be seen to meet more or less the requirements set forth to perfect the working of torpedoes. This arrangement of a trunk or well system could be applied to vessels of any class or size and placed not only to discharge in a fore and aft direction but also athwartships, in case of the beam of the vessel admitting of such an arrangement. In a larger class of torpedo boat, wells could be placed fore and aft, one for firing torpedoes ahead, and the other astern. It will also be a highly practicable proceeding to fit a trunk or well of this kind loaded with torpedoes in coal barges, provision boats, or any other unlikely looking engine of destruction, by means of which the greatest damage could be inflicted on one or more vessels in the most unsuspected manner. Considering the simple and perfect arrangement of mechanism used in this system of discharging torpedoes, the direct line of fire they obtain by being discharged under the keel of the attacking vessel; the advantage thus gained by obviating the disturbing influences experienced in breaking their course through the surface of the water, and the compact manner in which they are stowed immediately in the position required for discharging, this design is worth the greatest attention of all Governments interested in the destructive science of submarine warfare, and will doubtless in the immediate future become a subject of experiment and adoption by the various competing marine navies of our own and foreign countries.

SHIPBUILDING IN THE TEES DISTRICT.—During the past year Messrs. Raylton Dixon & Co., of Cleveland Dockyard, Middlesbrough, have launched 13 vessels, having a total tonnage of 25,036 tons. Their names are as follows:—Bothwell Castle, Juliet, Angier Head, Iron Acton, Uppingham, Lesseps, Popenjoy, Afrikaan, Chancellor, Jacob Christensen, Minard Castle, Zuid Holland, and Chittagong.

WEAR SHIPBUILDING RETURNS.—The following is a return of the ships built by Mr. James Laing and the Sunderland Shipbuilding Company during the present year. Mr. James Laing's list is:—Serpho, Ville de Lisbonne, Moscow, Oliveto, Congo, Charrington, Rhodora, City of Hamburg, and Laju; total tonnage, 19,413 tons. But for the late strike other two vessels, of the aggregate gross tonnage of about 7,000, would have been launched. The Sunderland Shipbuilding Company launched the Cascapedia, Hermann, Chateau Leoville, Harbinger, Bussorah; total tonnage, 13,000,

AN ACCOUNT OF EXPERIMENTS MADE BY A BOARD OF UNITED STATES NAVAL ENGINEERS WITH SCREW PROPELLERS OF DIFFERENT MATERIAL AND DIMENSIONS APPLIED TO THE UNITED STATES FISH COMMISSION'S STEAMER "LOOKOUT" WITH THE HULL COPPERED AND NOT COPPERED.

By Chief Engineer ISHERWOOD, U.S. Navy.

From the Journal of the Franklin Institute.

(*Continued from page* 196.)

SCREW *A* applied to the uncoppered vessel, and screw *F* applied to the coppered vessel, having very nearly the same diameter and fraction used of the pitch, but pitches of respectively 8·4 and 9·0 feet gave the same utilizations when that of screw *A* is corrected for the greater resistance of the uncoppered vessel, showing the difference of the pitches not to have affected the economic results. The utilizations of screws *A* and *F*, when equated for the resistance of the coppered vessel, are 66·8 per centum of the net power developed by the engine, consequently these two screws of $4\frac{2}{3}$ ft. diameter are

$\left(\frac{71{\cdot}3117-66{\cdot}8000\times 100}{71{\cdot}3117}=\right)$ 6·3267 per centum inferior to the four screws *B*, *C*, *D*, and *E* of 5 ft. diameter, the pitches and fractions used of the pitch of the former lying within the limits of those of the latter. This inferiority is caused wholly by the smaller diameter, whereby the loss of useful effect, due to the greater slip resulting from the less acting surface of screws *A* and *F*, more than counterbalances the gain due to the less resistance of the water to the less acting surface of those screws. The utilizations of screws *A* and *F* could doubtless have been much increased had the fraction used of their pitch been increased from about one-third, which it was, to one-half; or, had their pitch been decreased, retaining the same fraction of pitch.

The quantities on line 24 of Table No. 2, shows relatively the utilizations of the different screws, when the comparison is made directly by dividing the cubes of the speeds (line 2) by the net horse-power developed by the engine (line 15). The quantities on line 24 are the quotients of such divisions, and have very nearly the same proportions to each other as the quantities on line 23—considering the experiments with the uncoppered vessel separately from those with the vessel coppered—as appears from the quantities on line 25, which are the quotients of the division of those on line 23 by those on line 24. The equality of the latter quotients proves, 1st, that the distribution of the power in the different experiments, as given in Table 2, lines 13 to 23, both inclusive, is correct; and 2nd, that no difference in the utilizations results from the difference in the metals, cast-iron and cast brass, of which the screws were made. The only difference that could have resulted would have been due to the different surface textures of these two metals, whereby the resistance of the water per unit of their surface might have been different.

These experiments show what many others have shown when properly interpreted—that the utilizations of screws of different proportions of diameter, pitch and fractions used of the pitch, and of different outlines and inclinations of the blades applied to the same vessel, vary very little unless extreme variations of dimensions are resorted to. The outline and inclination of the blades appear to be absolutely without effect upon the utilization, which is controlled entirely by the diameter, pitch and fraction used of the pitch.

The experiments show also that the method of distributing the indicated horse-power developed by the engine, originally devised and long practised by the writer, is correct, and that by its means the important question of the resistance in pounds of the hull, *per se*, of a vessel at a given speed may be ascertained indirectly quite as accurately as by the direct application of a dynamometer.

The true performance and distribution of the power of the *Lookout* with her bottom coppered, when propelled by screw *E*, deduced from all the experiments, is as follows for the speed of 10 geographical miles per hour, the slip of the screw being 16 per centum of its axial velocity (product of revolutions and pitch); the number of its revolutions, 134·1711 per minute; the indicated pressure on the piston of the large cylinder, 23·4175 pounds per square inch, that cylinder being supposed to be used alone; the thrust of the screw or resistance of the hull, 1631·28 pounds, as herein determined; the indicated horses-power developed by the engine, 79·5393, and the pressure required to work the engine, *per se*, 2·7164 pounds per square inch of the piston of the large cylinder alone.

DISTRIBUTION OF THE POWER.

	Horse-power.		Per cent. of net horse-power.

CHARGE AGAINST THE CHIEF ENGINEER OF A WILSON LINER.

AT the Hull Police Court, Mr. Twiss had before him the case of S. Crawford, chief engineer of Messrs. Thomas Wilson, Sons, & Co.'s steamer *Rinaldo*, who was summoned by Captain Wm. Newman, master of the same vessel, for wilful disobedience to orders.—Mr. T. W. Hearfield appeared for the complainant, and, in opening the case, he stated that the defendant had sailed with the complainant for some time, and had always conducted himself with propriety until the last voyage or two. He appeared to have got the impression that, as chief engineer, he had the control over his part of the ship, and that he was not under the direction of the master. The present proceedings were therefore instituted to show that the master had the control of the vessel, and that it was the duty of all the crew to conform to his orders.—Dr. Rollit: We don't dispute that. We say that the master may give all the orders he thinks proper, but that we cannot carry out impossibilities.—Mr. Hearfield, continuing, stated that when the vessel was last at Cronstadt the cargo was being discharged, and it was found that there was not sufficient steam on the donkey boiler. The expeditious discharge of the cargo was thereby impeded, fewer labourers having to be employed. The master was informed of this, and about two o'clock in the afternoon he instructed defendant to get steam on the main boiler, so that more hands might be put on, and the work of discharging expedited. The chief engineer replied that they could not get steam on the main boiler until ten o'clock on the following morning, to which the complainant rejoined, "Very well, get it on as soon as you possibly can." At five o'clock the captain went on deck. He found no one in the stoke-hole, and noticed that no preparations had been made to get up steam. He (Mr. Hearfield) contended that the men ought to have been occupied in getting up steam. His Worship: And that the defendant neglected to give the necessary orders for this to be done is a wilful disobedience of the lawful command.—Mr. Hearfield: Yes. On the following morning a little before seven the master again went on deck and found no one in the stoke-hole. He subsequently saw the chief engineer, and asked him why his order had not been obeyed. Defendant replied that it was a rule to work from seven to five o'clock, and he was not going to differ. Captain Newman told him it was the the third time he had disobeyed his orders, and he should "log" him for wilful disobedience.—Dr. Rollit: We deny these facts, Steam was ready at the time named, and the work was being done.—Mr. Hearfield: He did not go and get steam up on the main boiler as soon as he might have done.—Captain Newman was then called. He said the *Rinaldo* was at Cronstadt on the 20th ult. At two p.m. on that day, acting from information given him by the chief officer, he ordered the defendant to get steam on the main boiler. It was not got up during the afternoon, and was not up at seven o'clock the following morning. He saw Crawford, and, in addition to his reply as to the hours, he said that Mr. Taylor, Messrs. Wilson's deputy-superintendent, had given him orders not to light the main boiler. Witness told him that Mr. Taylor had nothing to do with the ship in that instance. He (the master) was responsible, and if he were wrong, he would be made responsible for it. Defendant then told him that he would have him before Mr. Newbald and Mr. Cameron. Witness then said he should "log" him.—In reply to Dr. Rollit, complainant said it was his intention, if he had had steam on the main boiler, to have used it in discharging the cargo that night. It would have taken three hours to get steam up, and would have been ready a little after five o'clock. Work was discontinued for the day soon after six. Witness did not know that the boiler was being repaired. —In reply to his Worship, complainant said if steam had been got up on the main boiler that afternoon, it would have been ready between five and six o'clock. Work would have been discontinued about three-quarters of an hour after. His Worship: When you discovered at five o'clock that steam was not got up, why did you not see defendant?—The master: I had given him an order, and I did not think it necessary to repeat it.—Dr. Rollit, for the chief engineer, said they did not dispute the master's authority in any respect. He was the master of the vessel, and was acknowledged to be so by the defendant. His client was ordered to get up steam. He informed the master that he could not get it up until ten o'clock on the following morning. The boiler was then under repair, the repairs being necessary before it could be used. The master said he was to get it up as soon as possible. The boiler was repaired as quickly as possible, and, as defendant had promised, steam was got up at ten o'clock the following morning. It was not his intention to act in contradistinction to the master, and no disobedience was intended. He had witnesses to call in support of his statement.—Mr. Hearfield said that, after the explanation of Dr. Rollit, his client was fully satisfied with his authority being acknowledged, and he would not press the case further.—Mr. Twiss: I think this is a satisfactory termination. The summons will be dismissed.—No order was made as to costs.

THE NEW MARINE MONSTERS.

THE *Nautical Gazette* of New York says:—To our mind, steamers of the *City of Rome* type do not present the characteristics of success, either in point of naval architecture or business qualifications, in the transatlantic trade, such as their great cost should command. They may have and doubtless have many features which will make them popular ships with the traveling public, but the question is will they be remunerative to their owners. In size the *City of Rome* is imposing and attractive, but it remains to be seen if her huge proportions are not a great drawback when her success as a commercial venture is considered. Her model is by no means such a one as we should build upon, for she is not able to "stand on her feet" either in reasonable ballast or with a portion of her cargo in, and as soon as she begins to discharge she must begin to load or she will topple over, despite the heavy weights in her machinery department. Her crankiness is a terrible drawback. To coal her, she must be shored off the wharf, so that coal-boats can work on both sides at the same time, and thus become an obstruction to her neighbours' ships, and if the gang on either side of her knocks off work for a few minutes, the ship lists over quickly and she must be trimmed or she is down on her beam ends. Her maximum draft mark and her Plimsoll mark provides that she may go to sea legally drawing 31 feet of water, but this deep loading is only possible in leaving Liverpool, and cannot be practiced from this port with safety or surety, as the bar at Sandy Hook will not permit it. Therefore, we argue, the ship must of a necessity either go to sea partly laden or take large risks to her stern frame, propeller and rudder, if she loads down here to her legal draft. But from what we learn she by no means is able to carry cargo in proportion to her size, as her machinery and bunkers have made serious inroads upon her freighting capacity. Unless she comes up to her estimated speed, 17 knots, which, we think, she will not be able to do, it will be difficult to handle the inward or outward cargo in the usual time ships of her class lay in port at either end of the route. This would be another serious drawback, and tend to the slighting of the stowage of the cargo, which might result in serious injury to the cargo, if not to the ship herself. Her expenditure of coal, said to be over 200 tons per day, is a serions item of cost, especially if the price of the commodity reaches a high figure, as at times it does. The *City of Rome* took on board here, on her maiden voyage, 2,000 tons o coal, enough to load a moderate-sized steamer. To sum up, we hear that, from a commercial standpoint, this monstrous steamer cannot be termed a success. Certainly her "tenderness of stability," which is due to faulty designing and modelling, makes her a failure, so far as naval architecture is concerned. When west-bound freights are scarce, and coals high, we cannot see how she can "earn her salt" between Liverpool and New York, and, being so crank, we must expect that she cannot be driven to full speed, and as "time is money," such a trip, under such circumstances, would be a losing one indeed. We think the Inman Line was led into a grave error when it allowed itself to contract for such a large vessel, and it will find that should she have to be docked here to repair damages, it would be a very serious matter to handle her on our docks, and her only hope would be in the use of the coffer dam system. As the boys say, she is "too much of a good thing," and we think the stockholders of the company will agree with us ere many months roll around. Yet they may, as an offset, console themselves that she is next in size to the marine white elephant, yclept *Great Eastern*.

THE TWIN SCREW STEAM DREDGER "PROGRESO."

ON Thursday, December 8th, 1881, the *Progreso*, a twin screw steam dredger, was launched from the shipbuilding works of Messrs. J. & G. Rennie, of Greenwich.

The launch of this vessel is notable on account of the fact, that it brings a second contract for the Argentine Republic nearly to its termination. The first contract entered into by the firm mentioned, was for the building of a twin screw dredger named the *Riachuelo* and twelve hopper barges. The work they were required to perform, was to dredge a channel through the mud bank which exists at the mouth of the river Riachuelo, which would allow vessels of from 18 to 20 ft. draught, to enter that river and discharge their cargoes alongside wharves to be constructed for that purpose.

This river bounding as it does a large portion of Buenos Ayres, will become by being opened up in the manner the Argentine Government intend, a second Mersey or Clyde for ship-traffic and commerce. It is well known to all who are in any way acquainted with the navigation of the Rio de la Plata, that for the last half century, the immense mud bank which lies off Buenos Ayres, has been the greatest drawback to vessels wishing to discharge or take in cargo at that port on account of the great distance it was necessary for them to anchor from the shore, which was from two to three miles. About ten years ago, the government took into serious consideration the necessity of removing this great obstacle, to the development of their vast resources.

Their first step in this direction resulted in the determination to cut the channel referred to. For this purpose, a contract was entered into with Messrs. J. & G. Rennie, to build a twin screw dredger to be named the *Riachuelo*, capable of dredging about 400 tons per hour. The vessel was 156 ft. 6 in. in length; 28 ft. in breadth; 10 ft. 1 in. depth of hold, and 5 ft. 3 in. draught of water. The main engine worked the dredging apparatus, and by means of gearing propelled the vessel, and worked the winches for heaving ahead or astern.

To carry away the dredged soil and deposit the same in deep water, twelve hopper barges were ordered, 85 ft. long; 18 ft. broad. and 7 ft. 5 in. depth of hold. These were each capable of carrying 100 tons of soil. With this plant and the addition of a much smaller dredger, and a tug to tow the barges, the Argentine government in the course of between five or six years succeeded in cutting a channel through the mud bank three miles in length, 100 ft. in breadth, and 20 ft. in depth. They also dredged the river Riachuelo from its entrance for about two miles, to the depth of from 16 to 18 ft. The success following this undertaking was so great, that the Argentine Republic in 1880, decided to increase the depth of the channel, to increase its breadth from 100 to over 300 ft. (100 metres), and in deepening it, to dredge eight miles from the shore towards the bed of the river Rio de la Plata. The river at this part being about thirty-two miles in breadth. It was also decided to dredge the river Riachuelo for two and a-half miles of its length from the entrance, to a depth of 20 ft. To dredge and dig at the entrance on the right hand bank five large docks, and beyond these, to construct an unbroken line of wharves two miles in length. Large piers are also to be built on each side of the channel in the shallowest water, to prevent the mud silting up and closing it, whilst in the deeper portion occasional dredging will keep the channel open.

For this purpose a contract was entered into for Messrs. J. & G.

SCREW EXPERIMENTS (By Chief Engineer ISHERWOOD, U. S. Navy).

TABLE No. 2, Containing the Distribution of the Piston Pressures and of the Indicated Horses-Power during the Experiments made in 1880, in the Potomac River, by a Board of United States Naval Engineers with the Different Screw Propellers Applied to the Fish Commission's Steamer "Lookout," for the Purpose of Ascertaining the Best Proportions of Screw for that Vessel.

The piston pressures in this Table are the pressures that would have been upon the piston of the large cylinder had the pressures upon the piston of the small cylinder been reduced in the ratio of the net area of the piston of the large cylinder to the net area of the piston of the small cylinder, and the quantities thus obtained added to the observed pressures on the piston of the large cylinder. The capital letters at the head of the columns in this table designate the same experiments as are given in the columns of Table No. 1 with the same letter headings.

Rennie to supply two dredges and five hopper barges of much larger dimensions, and capable of doing a greater amount of work. In the first instance, the hopper barges, some of which are now on their way to Buenos Ayres, are each fitted with single screw propellers, and will carry in their hopper 300 tons of soil. The engines are inverted one high pressure cylinder 20 in. in diameter and one low pressure 38 in. in diameter, surface condensing. The boilers are cylindrical with horizontal iron tubes, suitable to 65 lbs. steam pressure. The boiler is 8 ft. 7 in. in length, and 8 ft. in diameter, with a heating surface of 700 square feet. The speed attained on official trial with the barges loaded to 8 ft. draught, was about 8½ knots, the contract being for 7½ knots. The barges are designed and constructed as efficient sea-going vessels, in compliance with Lloyd's Rules and the Board of Trade Regulations. Between decks forward there are two spacious cabins, one for the captain and the other for the chief engineer, and double bed bunks, lockers, &c., for the crew. For the passage out the hopper doors, besides being carefully hove up by means of the powerful winch at each end of the hopper, is firmly bolted and secured to temporary wooden cross beams, and well caulked. They are also completely fitted and rigged as schooners with a large flying fore course. The large dredger, *Progreso* just launched, is 175 ft. long, 31 ft. moulded breadth, and 10 ft. depth of hold. She is capable of dredging to a depth of 32 ft. The engines consist of a compound surface condensing high-pressure cylinder 29 in. diameter, and a low-pressure cylinder 50 in. diameter, with a stroke of 3 ft. The boiler is cylindrical, with horizontal iron tubes, suitable to 70 lbs. pressure, with a heating surface of 1,400 square feet. Its length is 18 ft., and diameter 8 ft.

A crab-winch is fitted in the bow for heaving the vessel ahead, when dredging with one centre barrel for head anchor chains, and two end barrels for shifting pins, buckets, &c., fitted with two cylinders, each 1½ ft. diameter, fed from the main boiler. The main engine used for dredging is 70 nominal horse-power, and is suited by means of gearing for propelling the vessel at about 8 knots per hour, or for working the 4 capstans placed one on each bow and one on each quarter for side dredging operations.

The length of the bucket-ladder is 81 ft. The number of buckets fitted for use at one time are thirty-two, each having a capacity of 15½ cubic feet, and capable, under ordinary circumstances, of dredging about 600 tons of soil per hour. The hull is constructed with every possible requirement for strength to class at Lloyd's, and extra stiffness under engines, boilers, and machinery, particularly the foundation to upright shaft to prevent shocks in dredging. Due attention has also been paid to the subdivision of the dredger (as likewise the hopper barges) into water-tight compartments. For the voyage out, she will be fully equipped and fitted as a three-masted schooner. The bottom of the dredging well will be planked and caulked, and the space used for cargo, &c.

Every accommodation is provided in the shape of cabins for the captain, engineers, boatswain and carpenter, and separate spaces fitted with double bed bunks, lockers, tables, cupboards, &c., for the firemen and seamen.

This dredger will be used for the deep channel work at the entrance to the Riachuelo.

The dredger to be used in the river Riachuelo, is erected ready for inspection before shipment to Buenos Ayres for re-erection and completion. She is named the *Lesseps*, and is built in the shape of an oblong tank, being perfectly square at the ends and sides. The dredging will extend right through the fore end to admit of the vessel cutting her way ahead as well as dredging to a depth in the usual manner. With the exception of the gearing for propulsion which is not required in this vessel, she is very similarly fitted to the large dredger on a smaller scale.

The Argentine Government are anxious to commence operations with this new dredging fleet, well knowing the great task they have before them, as, even with this addition to their dredging plant, it is calculated that from 15 to 20 years will elapse before the final completion of the operations, which will undoubtedly raise the port of Buenos Ayres to the position of the largest and most accommodating haven on the south-east coast of the Continent of South America.

AN ironclad corvette, which has been built in the Vulcan Dockyard for the Chinese Government, was successfully launched in the presence of General von Stosch, Chief of the German Admiralty, and Herr von Boetticher. The Chinese Ambassador performed the office of christening the vessel, giving it the name of *Tingyuen*.

OUR ROYAL MARINE ENGINEERS AND ENGINE ROOM ARTIFICERS.

MUCH has been said and written of late concerning our Royal Naval Engineers, and the necessity of improving their status in the service as officers and gentlemen. The origin and development of the royal naval engineer as an important addition to the ever-increasing requirements of our improved men-of-war is a matter deserving the consideration of all interested in the art and progress of marine engineering, and a general knowledge on this point may be obtained without referring to a remote date, seeing that the engineer was introduced into the service well within a half-century ago. During the earlier portion of this time our war vessels were fitted with paddle wheels and single screws, the propelling engines in each case being of a comparatively simple form of construction, the power developed by the engines was also particularly small when compared with the powers now worked to, and the amount of coal carried by a first-class wan-of-war between 30 and 40 years ago was ridiculously small. In fact, during the first half of the time in which steam propulsion has been employed in our royal Navy the propelling power of the machinery only held a secondary position in driving the vessel, the sail power being the primary agent of propulsion. In the earlier stages of the royal marine engine it was only applied and used as an auxiliary power, which was very handy in the case of prolonged calms, head winds, and on nearing land or going into harbour. The introduction of the engineers and stokers in very limited numbers, as compared with the immense crew of admiral, captain, commander, lieutenants, sub-lieutenants, midshipmen, warrant officers, quartermasters, petty officers, and seamen, in our ships of war was looked upon by our older seamen and officers as an unnecessary nuisance and infliction; and even the benefit of progressing on a voyage through a dead calm, making good headway dead in the teeth of a gale, or saving the vessel from being driven on a lee shore, hardly compensated our old man-of-war's man for the dirt, grime, and smoke introduced by the use of the machinery in their otherwise scrupulously clean ship, destroying once and for ever the snowy whiteness of decks and sails, which our former navy excelled in and prided itself upon, as compared with foreign navies. In this earlier stage of the existence of the royal marine engineer, the position they held on board a man-of-war was in many cases a most unenviable one. The commissioned officers of all grades kept aloof from them, the chief engineer of the vessel excepted, he being rated as a ward room officer, and *allowed* to mess with the lieutenants, paymasters, and surgeons. The other engineers, at this period, had a mess and living cabin combined, of very limited dimensions, outside of which they slung their hammocks at night. During their hours of recreation the commissioned officers of the vessel enjoyed their cigar and chat over the full area of the quarter-deck (that is from the mainmast to the taffrail); the sailor smoked, sang, danced, and frolicked on the forecastle, whilst the marine engineer officers, a solitary few, unable, owing to the name they bore as officers, to join in the sports of the seamen, and not privileged to tread the sacred boundary of the quarter-deck, slowly paced the narrow and confined portion of the vessel termed the waist, a narrow strip of deck on each side of the boiler and engine-room hatch, which formed a kind of neutral ground between the commissioned officers and the seamen.

About 25 years ago the introduction of the armour-clad in our navy, and an increase in the size and power of the engines and boilers to produce a higher rate of speed, as well as to propel a much greater weight, drew some official attention to the use and value of the royal marine engineer. As the supply of this branch of H.M. service was principally obtained from mechanical and marine engineers and fitters from our royal dockyards, it was considered by the Admiralty that, as steam machinery was bound to form a leading feature towards the perfection of our man-of-war, it would become incumbent on them to train and fit practical and theoretical engineers, competent to manage and improve the complication of mechanism our marine engines at that time were beginning to develop. Previous to this, the marine engineer obtained from our royal dockyards was entered into the service, in the first instance, as a factory boy, and engaged in the various machine and boiler shops of the engine factories till he reached the age of manhood, when, according to his ability and skill as a mechanical marine engineer, he would obtain a recommendation and a rating as an engineer in H.M. Royal Navy. The perfecting himself in the theory of his profession was a matter left entirely to his own taste. The importance of the marine engine, and necessity for improvement in knowledge and skill in this direction, led the Admiralty, at a later date, to issue an order that, for all entries into H.M. dockyards of lads to be trained and fitted as marine engineers, a strict Civil Service examination was to be instituted, and only a limited number of competitors to be chosen, all of whom were to obtain over a certain number of marks in each subject they were examined in. These successful competitors were to be indentured marine engineer apprentices. Not satisfied with this, these lads were required to attend a Government school during a portion of their time for the first three years of their apprenticeship, and to compete at examinations in higher subjects every six months; the most promising lads being employed, as their knowledge of the practical part of their business increased, in the different drawing and designing offices, and finally passing trying examinations to gain an appointment in the royal navy as third and fourth class engineers.

* OCEAN STEAMSHIP MACHINERY.

A SERIES OF PRACTICAL PAPERS ON THE DESIGN, CONSTRUCTION, AND MANAGEMENT OF THE MACHINERY OF STEAMSHIPS.

By H. Holt-Butterfill, Marine Engineer.

As no work, to the Author's knowledge, at present exists, which covers the same ground or gives the kind of information, which is attempted to be conveyed in these papers, in a way to be of direct *practical* use to the classes for whom they have been specially prepared, he deems it unnecessary to offer any apology for their appearance now.

The great demand, which is looming in the immediate future, for a more thorough technical and trade education than now obtains for our managing engineers, sea-going engineers, draughtsmen, foremen, and workmen, encourages their author to hope that these practical papers, which are the results of many years' experience in the office and workshop and on ship-board, may supply a want which has long been felt by all who have had anything to do with the production and management of ocean steamship machinery.

The subject-matter of our papers embraces in detail all the machinery and accessions now required in an ocean-going steamship, and the work we set ourselves to accomplish in connection therewith being for the special information of a not unimportant section of our industrial community, many members of which have not had opportunities of obtaining a mathematical training, we have endeavoured to give to our remarks as practical a character as possible, and not to burden them with abstruse theoretical investigations of the great principles involved in the action of the motive power of steamships—a subject which has already been so ably treated by others—but rather to make use of the results of those investigations as they bear upon the subject we have under discussion.

Nor has it been our purpose in these papers to enter at any length into that interesting subject—" the history of the application of the motive power of steam to the propulsion of vessels at sea "—it being, we think, sufficient for our readers to be informed on this head as to the reliable facts obtainable in connection with the more modern *successful* application of means to that end.

We have in all cases, so far as it is possible, given such information on all the matters that come under consideration as we think is necessary to be known by the student, and although we have in a previous paragraph eschewed *abstruse theoretical investigations*, we do not thereby imply an intention to discard theory altogether, for without it there can be no successful practice.

Our aim has been to combine the theory of each part of the subject with its practical application, that the student may be led to see the inter-dependence of each with the other, and be brought to the conclusion that to become a successful engineer it is necessary that he should understand the *why* and the *wherefore* of every part of his design, and the special purpose it is intended to serve.

So far as the "construction" of the machinery of steamships is concerned, we have not thought it necessary to enter into those details of workshop practice which every studious workman and apprentice will see to be to his interest to thoroughly master. But where *principles* and *laws* are involved, as in changing the nature of movements, friction, &c., we have endeavoured to explain them as concisely as we are able, and have shown how the results of the reasoning are practically applied.

As upon the correct adaptation and fitment of the machinery to the ship, much of her future success in the matter of her propulsion through the sea will depend, the latest practice of the best of our marine engine builders is given in detail when treating of these matters. And as the successful application of the screw propeller is still an unsettled question, the latest reliable results obtained in practice as to form, proportion, &c., are given in their appropriate place.

The judicious *management* of steamship machinery, both in port and at sea, forms a special feature in these papers, as upon it so largely depends the success of a steamship as a commercial venture, and as fulfilling the intentions of her builders in the matter of realized power, speed, and consumption of fuel.

As in these days of rapid passages, incessant employment, and short stoppages in port of ocean-going steamships, the care of the *hull*, in a measure, devolves upon the engineering staff, the results of a practical experience of some years in these matters is given in the hope that they may be found of service to many who may wish for such information.

The type of machinery discussed in these papers is that which now usually prevails in ocean-going steamships—viz., single or double compound inverted direct-acting surface condensing engines, with either single or double-ended circular return tube boilers, together with all the accessories required for feeding boilers, pumping ship, discharging and taking in cargo, and working ship at sea or in harbour.

It is assumed that all who seek for information in these papers are practically acquainted with arithmetic and elementary algebra, and have sufficient knowledge of mechanical drawing to be enabled to follow the directions given in getting out the design of any portion of machinery under description.

BOURRY'S IMPROVEMENTS IN STEAM BOILERS AND STEAM JOINTS.

THESE improvements are embodied in a most characteristic way, as will be shown by reference to the accompanying plate. This plate represents a horizontal marine boiler, capable also of application for stationary and many other purposes. It will be seen to consist of the type known as the water-tube boiler, constructed by a most novel arrangement of tubes and joints. The main purpose in the present construction of water-tube boilers is the reduction of weight to the lowest possible limit by employing but small thicknesses of material throughout, and yet combining unquestionable safety, together with the exclusion of all heated surfaces which are not actually steam producing. The most striking peculiarity noticeable in the plan followed out by M. Bourry in his method of construction is the formation of the very walls or boundary of the whole boiler by rows of tubes, in close longitudinal contact, and at right angles to each other, fastened to the sides of somewhat larger tubes, whereby a square-looking, box-like body is established, the larger tubes forming the corners, and the rows of smaller tubes the sides. The contents of all these tubes together constitute the water spaces between the fire side and the outer atmosphere.

Within the hollow space bounded by the four tube-walls are superposed rows of still smaller tubes connecting pair by pair the corresponding side tubes opposite each other, and between which the fire and heated gases are made to pass.

In order to preserve the advantage of accessibility without loss of heat by radiation, and any sensible addition of weight, the usual casing of non-conducting material is replaced by a jacket of thin sheet metal, leaving a certain layer of air between by a current, of which the radiated heat from the boiler is carried off and through the grate to the fire, in which way it is completely turned to profit again, while the surroundings remain perfectly cool; a most appreciable advantage on board ships, where so many efforts are made to keep the stoke-hold cool, necessitating in large vessels—especially the man-of-war class—a complex ventilating arrangement.

The junctions of this novel form of boiler are made in the following way :—The bosses of the corner tubes are tapped inside; so is also the widened end of the side tubes for a limited distance. Further on a very smooth cone is made tapering towards the inside of the tube; the ferrule, which is provided with a little socket at its end, receives therein a well-fitting ring of copper or other soft metal, the outer diameter of which corresponds exactly with the base of the cone in the side tube. On screwing in the ferrule the ring is pushed forward and forcibly compressed within its socket until complete tightness is obtained.

At the same time another similar ring in a socket made on the inside of the corner tube boss is also compressed by the action of a conical part of the ferrule; the said two rings by their particular position cut off all access of steam or water to the screw thread, whereby the latter is secured against oxidation, and does not offer any exceptional resistance to unscrewing. The screw plugs closing the holes through which access is had to the connections, and which also serve for cleaning, are likewise provided with a cone compressing a light ring as above for making a tight joint, and being also situated on the water or steam side of the screw thread to preserve the latter against deterioration.

It will thus be seen that the compression of the interposed body for effecting tightness is not taking place in the direction of the axis as usual, but either radially or concentrically. The boiler illustrated in accompanying plate will convey a general good idea of the improvements and particular construction above noted. *A A* are the corner tubes, *B B* the side tubes, and *C C* the cross tubes. The hollow spheres, *O O*, belonging half to the water space and half to the steam space, are intended to obviate all fatal undulations in the total water level arising from the motion of the ship or from differences in the degree of ebullition along the boiler. The cylinders, *N N*, contain nothing but steam, and are connected to the spheres by elbows to give the necessary flexibility for unequal expansion; *K* is the uptake attached to the smoke-box, which reaches into the boiler to where the cross tubes commence from that side; it is made to keep off the contact of the heated gases with the last couples of side tubes in order to favour the return current of the water therein; *L* is the smoke pipe.

The grate, *G*, consists of a certain number of parallel water tubes lengthways with the boiler, and terminating at each end in larger tubes which run across; of these only one is connected to the sides of the boiler, forming the water spaces; the other is merely supported in its middle by the feed water-pipe to admit of a free expansion and contraction of the whole of the grate; the feed water is first directed from behind through the grate before entering the boiler, as by its lower temperature it prevents the presence of too much steam in the grate tubes, and preserves them best from burning through; *R R* are baffle plates vibrating round the corner tubes $A^1 A^1$, and serving to direct the air current at will, up or downwards through the grate, in which latter way the furnace becomes smoke-consuming, and affords also greater facility in stoking. The left side of **Fig. 3** shows the relative position of said plates for the up, and the

BOURRY'S IMPROVEMENTS IN STEAM BOILERS AND STEAM JOINTS.

right side for the down current. The air between this boiler and its jacket may be caused to flow when heated by radiation through the burning fuel, in which case the front plate is made double.

EXPERIMENTAL RESEARCHES INTO THE PROPERTIES AND MOTIONS OF FLUIDS WITH THEORETICAL DEDUCTIONS THEREFROM.

By W. F. Stanley.

THE treatment of this highly important subject by the author opens up a large amount of new theory in the principles of the sciences of hydrodynamics and acoustics; the volume containing the results of observations and experiments most carefully conducted and worked out by several years of application and study, although embodying between 500 and 600 pages, is so full of explanations leading up to the simpler application of mechanical laws to all fluid matter that every chapter and page will be followed with interest, and it will be seen that nothing has been overlooked to render this work as complete as possible, and that none of the matter could be spared without breaking the continuity and regularity which every problem has been worked out, and each result arrived at. The writer of this valuable work had been formerly engaged in close experimental examination of the undulatory theory of light. Observing the similitudes of the motions of water waves and sound waves, he decided to extend his observations to become assured if these conceptions were real. It was believed by Mr. Stanley that in science, with respect to fluids, too great reliance had been placed on some ingenious theoretical idea, which was not clearly and sufficiently supported by direct observations, or by experiment, therefore necessarily only brought to bear on facts by the introduction of somewhat arbitrary functions, whereas too little dependence had been placed on purely inductive methods. The investigations here laid before us are conducted on the theory that oscillation enters as a principle into wave motions at all times, although most evidently in the dissipation of impressed forces to equilibrium upon the open liquid surface. The first chapter contains some theory on the fluid condition consistent with acquired knowledge the matter, and with experiments made by the author, particularly to account for the rigidity and yet mobility of liquid systems.

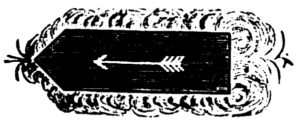

Fig. 1.

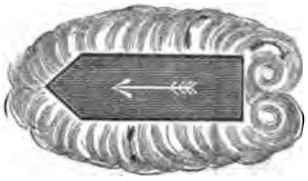

Fig. 2.

It is here shown that fluidity may be taken to be a very general physical property of matter in some degree, and this has been taken advantage of in some of the experiments made in the work before us. At the same time, a perfect state of fluidity does not exist in any material body, all fluids being found to be in different degrees cohesive, viscid, plastic and elastic, possessing internal construction of parts; or chemical arrangements which do not admit of a perfect mobility of the separate parts which would be necessary for the condition of perfect fluidity. The apparent homogenity of fluid matter, the constructions of atoms, gases and liquid molecules, the cohesion of liquid molecules, and general remarks on fluidity, are set forth and explained in the opening chapter. The 12th propositions setting forth the elastic rigidity of the fluids, air and water, as of the same kind as that observable in gelatinous bodies, agrees with other former experiments in this direction, and the whole chapter is well illustrated by diagrams explaining the author's experiments and results, the nature of these being so connected that it is impossible to notice or discuss any particular portion apart from the whole. The 2nd chapter, enters into the conditions of liquid surface; capillary action; tension of films; bubbling, boiling and evaporation. In this chapter, the author differs from the generally accepted theory of *tensile* surface for liquids, founded on the researches of many former philosophers, and takes quite an opposite view, viz:—that such surfaces are *extensile* instead of tensile; except for free films, which are clearly *tensile* by the attractive matter which composes them. In defining tha words *tensile* and *extensile*, it should be taken that *tensile* is a disposition of the parts of a system of matter to draw themselves together as a stretched drum-skin does, and *extensile* the reverse of this, or the disposition of the parts of a system of matter to separate and thereby to engender external pressures. The theories and propositions given in this chapter, have so far as worked out and explained everything to recommend them to the careful study and application of theroists.

Chapter 3, on flowing forces, contains examples and equations on oblique and gravitation impulses; efflux and directive forces; traction and cohesion on traction of liquids. The examples given on the movement of a liquid toward a hole in the bottom of a vessel, the action of hydrostatic pressures with gravitation over and about the hole, &c., is a subject demanding such attention, that a future notice on this head, comparing the theories put forward with existing theories and the methods of mechanical application, will be necessary to convey an adequate idea of the value of this chapter.

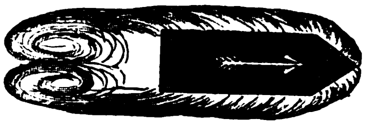

Fig. 3.

Chapter 4. We here find the author introducing a theory of the motion of fluids entirely new, in many respects, which may be condensed in the words "that fluids move by *rolling contact* upon their own parts and upon solids." The propositions and definitions given on the motive contact of fluids upon solids, and upon parts of their own or other systems, with the principles of rolling contact in fluids moving upon lateral resistances, calls for the closest attention of our shipbuilding theorists and mathematicians, as also our civil engineers. The ship designer and calculator should consider the frictional skin resistances on vessels moving through the water as that of a continual rolling contact, which would alter the formulæ now in existence on skin resistance; and the civil engineer would likewise profit by considering the fluid motion on inclines and through pipes as that of a rolling motion, to some extent at the sides of the pipes and on the surface of the inclines. The examples and illustrations of this original theory will be found sufficient for application and improvement.

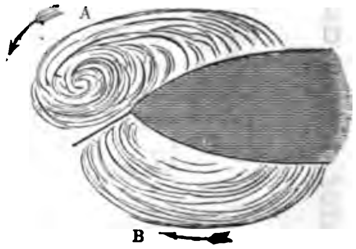

Fig. 4.

In the 5th and 6th Chapters the author offers principles of conic resistance in fluids, which give simple mechanical laws for the class of motions sometimes defined as vortices, eddies, and cyclones. Examples of conic fractures of water, projectile rotation. Whirl and bi-whirl projections produced by various experiments are very fully recorded and illustrated, and the author states "that these mechanical laws may be ultimately shown to be generally, if not the universal, principles upon which all fluids move by displacement upon themselves; which will open out new theories of fluid motion."

Chapter 7 is a continuation of the laws and forces laid down in the two preceeding chapters.

Chapter 8. On the principles of motive projection of free solids in extensive fluids enters a field of work which has received the unremitting attention of such well know theorists on the resistence of bodies moving through deep water, and on various wave theories Mr. Froude, Dr. Woolley, Mr. Scott Russell, Mr. Rankine, and many others with whose ideas and experiments we must at some future time deal and observe how far they work in with those of Mr. Stanley. Figures 1, 2, and 3, represent bodies projected through water at different velocities. Figure 1 is a slow projection with a velocity of slight resistance showing motions of rolling contact having ample time for fluid accommodation in small space to engender thereby a close system of projectile force. Figure 2 is a moderate rate of projection with a velocity of highest relative, resistance for the mass of fluid displaced; the cohesive force upon the vessel being sufficient to engender contact whirls to the greatest possible distance giving the broadest system of projectile whirls. Figure 3 is a rapid projection with a velocity of diminishing resistance, or of fracture of cohesive form, the whirl system being incipient for want of time, the cohesive force partially breaks the liquid and the vessel is set relatively free in proportion to the amount of fracture. Figures 4, 5, and 6, following these experiments shew also the action of water, by the authors whirl system, on rudders at different speeds. As this is a matter of great interest to the MARINE ENGINEER, and has received a large amount of study and observation which to a great extent governs the size and shape of rudders fitted to different vessels we must also deal with this as a special subject on some future occasion. The 1st section of the volume which contains the greater half of the matter given, closes with some facts on diffusion of fluid forces which the author considers may need more experimental demonstrations that he has given.

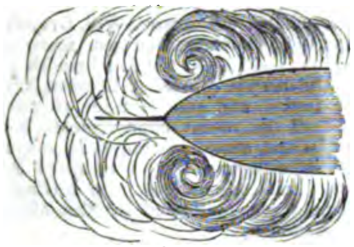

Fig. 5.

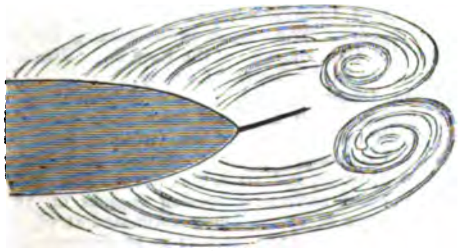

Fig. 6.

The second section of this work is devoted to the discussion of cosmical phenomena in fluids, in some parts following certain ideas proposed by Lenz, Herschel, and Dr. Carpenter. The author having discovered and introduced further principles of motions in fluids, proposes certain universal systems of motions for fluids upon the globe; consistent with the distribution of land and water as it exists, and at the same time as will constantly influence this distribution. These researches may aid in the elevation of the sciences of physical geography and meteorology, now sciences of *observation*, to sciences of *principle*; to rank at some future period with such exact sciences as astronomy and chemistry; but as they are at present proposed, may be considered only the commencement of systematic work in this field of research.

Section 3 on waves contains many experimental inferences which agree most nearly with ideas first published by M. Flangergues, in the *Journal de Sçavans*, 1789, and in some instances assisted by the experiments of Mr. J. Scott Russell. Throughout this section the motion of rolling contact is systematically followed out and worked up to; and, although an original development of ideas and experiment by the author is to a certain extent embodied in his theory of waves, it agrees in many instances with the ideas and experiments of other authorities on this subject, to which, as in the other instances mentioned at some future time, we will give further attention by comparison.

THE close of the year 1881 will be particularly memorable in the annals of the Iron Shipbuilding Trade. This year opened with promising prospects for this branch of industry, which have been in every way most fully realized. The northern and north-eastern districts have reaped the greatest harvest out of the highly improved condition of trade, whilst a steady improvement has also been observable in the usually quiet state of affairs in the southern districts. On the Clyde the shipbuilders' have completed work which exceeds the hitherto well-known year of 1874. At the end of November, 1881, the number of tons completed during the eleven months of the year reaches the large total of 290,000. This is 27,500 tons in excess of the amount completed in 1874, which will be considerably augmented during the month still remaining. The number of vessels launched in November was twenty-four, representing a total of 31,600 tons. In November, 1880, it amounted to 25,410 tons; in 1879 to 20,240 tons; in 1878 to 23,903 tons; in 1877 to 21,000 tons; in 1876 to 30,000; in 1875 to 28,500 tons; and in 1874 to 20,000 tons. Notwithstanding the large amount of work completed, employers are fully occupied, and large orders are still being booked and contracted for. On the Tyne, although the output of work is not on such a large-scale as that of the Clyde, shipbuilders' have experienced a very busy year. In most of the yards the building slips are full, and in many cases orders are waiting in hand for keels to be laid, as soon as space can be obtained by launching. In the Tees district the state of the shipyards is in a highly satisfactory condition, and the year will close in a most succesful manner, which is rendered more encouraging by the prospect of a much more busy year in 1882. Sunderland, Middlesbro', Hartlepool, Shields and Hull, with building and repairing contracts have generally been fully employed throughout the year, and together with the shipbuilding community mentioned, have still better things to look forward to in the future. Liverpool and Birkenhead are enjoying a fair share in the long looked for revival of the shipbuilding trade, and even London (the deserted centre of this industry), Southampton, and smaller seaports in the south, will, at the close of 1881 experience a greater feeling of satisfaction than has fallen to their share for some years past. In recording briefly the shipbuilding progress of the year just closed it is pleasant to find that, together with other interests, this important branch has risen so much from the stagnation which has for some time attended it, and it is a still greater pleasure to be able to look forward to the coming year with hopes of increased prosperity in this direction.

DUNDEE SHIPBUILDING IN 1881.—Dundee has shared in the prosperity which has attended this branch of industry during the past year on the Clyde and elsewhere. During 1881, 11 vessels of 18,945 tons have been launched. Last year 15 vessels of 15,621 tons were completed. Thus it will be seen that though in 1881 there are four fewer ships, the size of the vessels is so much greater that their combined tonnage exceeds by 3,324 the total of 1880. Coming to the work on hand, we find that this year 16 vessels of 21,758 tons are contracted for, while last year at this date 7 vessels of 14,925 tons were ordered—thus showing an increase this year of 9 vessels, or 6,833 tons. The tonnage launched, as also that on hand, is the largest for the last 11 years. Though this year the number of vessels built is scarcely one-half of that in each of the years 1875 and 1876, the total tonnage is very much in excess of the years mentioned, showing clearly the preference which shipowners have for a larger class of vessels. Taking the work of the individual firms, Messrs. Gourlay Brothers & Co. have completed three vessels of 11,169 tons, while they have orders for six of 10,608 tons. Messrs. Alexander Stephen & Sons have launched four vessels of 3,859 tons, and have on hand three of 3,320 tons. Mr. W. B. Thompson have turned out four vessels of 3,917 tons, and has contracted to build seven of 7,830 tons. Messrs. Pearce Brothers, of Lilybank Foundry, have acquired ground for a shipbuilding-yard. Mr. W. B. Thompson has also made application to the Harbour Board for three additional slips. Altogether there seems a prospect of great activity in the shipbuilding trade during 1882.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of* The Marine Engineer *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—Ed.]

LAUNCHES.—English.

Elise.— On December 3rd there was launched from the shipbuilding yard of Messrs. Joseph L. Thomson & Sons, North Sands, an iron screw steamer of 3,150 tons burthen, built to the order of Messrs. James Gray and partners, of Whitby, for the Indian and Atlantic trades. This vessel has been constructed under special survey, and is of the highest classification at Lloyd's. The engines will be fitted by Mr. John Dickinson, of Palmer's Hill Engine Works, and are 180-horse power nominal; four horizontal steam winches, patent windlass, anchor, crane, Messrs. Cooper & Taylor's steam-steering gear (manufactured by Mr. John Lynn, of Sunderland), fresh water condensers, and all modern appliances for the efficient working of the vessel will be supplied. The naming of the vessel *Elise* was performed by Mrs. Gray, of Whitby.

City of Antwerp.—On December 5th, there was launched from Messrs. J. Blumer & Co.'s Yard, Sunderland, a screw steamer, of the following dimensions:—Length, 200 ft.; beam, 30 ft.; depth, 14 ft. 6 in. She has been built to the order of Messrs. Palgrave, Murphy, & Co., of Dublin and London, and has the highest class at Lloyd's, also Board of Trade passenger certificate. She is on raised quarter-deck principle, and has double bottom throughout for water ballast. Her main deck is of iron, and she is fitted with complete 'tween decks, four powerful steam cranes, and all other arrangements suitable for her intended trade between the Continent and Irish ports. She is to carry 1,000 tons on 13 ft. 6 in. draught, and is intended to steam 11 knots fully loaded. Higginson's steam quartermaster will be fitted for steering amidships, and Davie's patent steering gear aft. Her engines of 120-horse power will be supplied by Messrs. T. Richardson & Sons, Hartlepool, with all their latest improvements. On leaving the ways she was named *City of Antwerp* by Mrs. Lamont, wife of Captain Lamont.

Lavion.—On December 5th, a screw steamer for La Société Francaise des Steamers de l'Ouest (Messrs. Menier & Co.) was launched from the yard of Messrs. Schlinger, Davis & Co., Wallsend:—Length, 260 ft.; breadth, 33 ft. 6 in.; depth, 20 ft. 6 in. She will be classed 100 A 1 at Lloyd's. She has been built under the inspection of Lloyd's Surveyor on behalf of the owners. As she left the ways she was named the *Lavion.*

Antverpia.—On December 6th, Messrs. C. S. Swan & Hunter, Wallsend-on-Tyne, launched an iron screw steamer, 295 by 37 by 25, built for the Société Anonyme Anversoise d'Armement et de Transports Maritimes. The vessel was named *Antverpia* by Mrs. G. B. Hunter. She is intended for the East Indian trades, and will carry about 3,300 tons dead weight. The vessel will be fitted with engines of 35 and 68-45, made by the Wallsend Slipway and Engineering Company (Limited).

James Whishaw.—On December 6th, Messrs. M. Pearse & Co. launched at Stockton-on-Tees, an iron screw steamer, of the following dimensions:—Length, 250 ft.; breadth, 34 ft.; depth, 19 ft. 6 in. This vessel is about 1,600 tons gross register, and will carry about 2,150 tons dead weight. She will be classed 100 A 1 at Lloyd's; has short full poop aft, in which is fitted a saloon with the usual accommodation; has double bottom for water ballast; will be rigged as a two-masted schooner; has four steam-winches, and all the most recent and improved appliances for expeditiously loading and discharging cargoes. Her engines are of 150-horse power nominal, by Messrs. Blair & Co., of Stockton. This steamer has been built to the order of Messrs. Tulley & Co., of Hull, and is the fourth Messrs. M. Pearse & Co. have built for the same owners. As she left the ways she received the name of *James Whishaw*, from Mrs. R. G. Johnson, of Beverley, daughter of the managing owner.

Dauntless.—On December 6th there was launched from the yard of Mr. J. T. Eltringham, Stone Quay, South Shields, an iron paddled tug. Her dimensions are 108 ft. by 18 ft. 9 in. and 10 ft., and she will be fitted with a pair of surface condensing disconnecting engines of 70-horse power. This vessel, which is named the *Dauntless*, and has been built to the order of Messrs. J. P. Rennoldson & Sons, who are the makers of the engines, and is owned by the Waterford Steamship Company (Limited), of Waterford, by whom she will be employed in towing and passenger services.

North Cambria.—On December 6th there was launched from Messrs. Palmer's, Shipbuilding and Iron Company (Limited) yard, at Howden, an iron screw steamer of the following dimensions: — Length, 270 ft.; beam 36 ft.; depth, 24·6. She has been built to the order of Messrs. Hugh Roberts & Son, of Newcastle-on-Tyne, on the principle of cellular construction, having water ballast tanks fore and aft, forming a double bottom the whole length of the ship. She has long bridge, poop and topgallant forecastle; four steam winches, patent steam steering gear, steam starting and reversing gear, and all the latest improvements in hull and engines; classed 100 A 1 at Lloyd's, having been built under special survey, and will carry about 3,000 tons deadweight; is intended for the American, Indian, and general trades. The vessel as she left the ways was christened *North Cambria* by Mrs. Griffith Roberts, wife of the junior partner of the firm of Messrs. Hugh Roberts & Son.

Everest.—On December 6th Messrs. Wm. Gray & Co. launched from their yard at West Hartlepool an iron screw steamer, of the following dimensions:—Length, 262 ft.; breadth 34·6 ft.; depth, 19·8 ft.; built to the order of Murrell & Yeoman, West Hartlepool, intended for the Indian and general trade, to carry 2,400 tons. She is fitted with all the recent improvements, including double bottom for water ballast, steam stearing-gear, steam winches, and patent windlass. The engines are to be fitted by Messrs. Blair & Co., Limited, Stockton-on-Tees. On leaving the ways the christening ceremony was performed by Mrs. Murrell, the vessel being named the *Everest.*

Lynx.—On December 8th a fishing smack, cutter-rigged, was launched from the shipbuilding-yard of Messrs. John & Daniel Dewdry Brothers, Brixham. She is owned by Mr. W. Furneaux, of Brixham, her tonnage being 43 tons register, and she is named the *Lynx.* She is intended for the Brixham fishery.

Victoria Regina.—On December 10th Messrs. Oswald, Mordaunt & Co. launched from their shipbuilding and engineering works, Southampton, an iron sailing ship of 2,000 tons register, named the *Victoria Regina*, built to the order of John Coupland, Esq., Goscote Hall, Leicester, of the following dimensions:—Length 270 ft.; breadth, 39 ft. 6 in.; depth of hold, 24 ft. The ship is built with full poop, monkey forecastle, and large midship house for crew. She is fitted with Harfield's patent windlass for lifting anchors, and all the latest improvements. She is intended to class 100 A 1 at Lloyd's, and twenty years in the Liverpool Underwriters' registry. The ceremony of naming the vessel was performed by Mrs. Caussey, wife of the Captain. When fitted out she will be commanded by Captain Caussey.

Zodiac.—On December 10th Earle's Shipbuilding and Engineering Company, Hull, launched from their yard the steamship *Zodiac*, built to the order of the Grimsby and North Sea Steam Fishing Company (Limited). She is 92 ft. between perpendiculars, 20 ft. beam, and 10 ft. 6 in. deep. She will be propelled by compound surface-condensing engines of 35 nominal horse power, her rate of speed being estimated at 9¼ knots per hour. Her cylinders are 17 in. and 32 in. in diameter, whilst the stroke is 18 in. The steamer when launched not only had her masts and rigging in position, but her engines and boilers were also on board.

Sultana.—On December 19th, there was launched from the shipbuilding-yard of Messrs. Robert Thompson & Sons, Southwick, Sunderland, an iron screw-steamer, built for John Redfern, Esq., of Hull, of the following dimensions, viz.:—Length over all, 300 ft.; breadth, 35½ ft.; and depth of hold, 23 ft. 9 in. The vessel has been constructed to class 100 A 1 at Lloyd's under the three-decked rule. She has water ballast throughout both holds, five watertight bulkheads, iron main and wood upper deck, and is fitted as a two-masted schooner with double topsails. The poop aft is fitted up with accommodation for the captain and spare berths, bridge amidships for officers, topgallant forecastle for firemen and crew. She is fitted with four steam winches and donkey boiler to work four large hatchways, Emerson, Walker & Co.'s patent windlass, patent steam steering gear by Amos & Smith, Hull, screw gear aft, and all the latest improvements, and will also have engines 37 and 68 by 42-in. stroke, with two very large boilers 80 lbs pressure, by the North-Eastern Marine Engineering Company, South Dock, Sunderland. As the vessel left the ways she was christened the *Sultana*, by Mrs. Frost, wife of the Captain.

Gulf of St. Vincent.—On December 21st, Messrs. Wm. Gray

& Co. launched from their yard an iron screw-steamer of the following dimensions:—Length over all, 300 ft.; breadth, 38 ft.; depth, 27 ft. 3 in.; built to the order of the Greenock Steamship Company, Greenock, and intended for general trade, to carry 3,500 tons. The vessel has been built under the personal supervision of Captain Cook, the superintendent for the company. She has spacious 'tween decks for carrying horses or cattle, and is fitted with all recent improvements, including steam steering gear amidship, screw gear aft, and Napier's steam windlass and steam winches; she is fitted with a double bottom entire on the cellular principle, and is in other respects extra strong beyond Lloyd's requirements for the highest class, having two strokes double on topsides and two extra watertight bulkheads; the main and spar decks are of iron, the latter being covered with teak. The engines are to be fitted by Messrs. Blair & Co. (Limited), Stockton-on-Tees, of very high power, as the vessel is intended to be a fast sailer, her lines being fine. The christening ceremony was performed by Mrs. Lawrence, of the firm of Westcott & Lawrence, the London agents of the Company, the steamer being named *Gulf of St. Vincent*, and is to be commanded by Captain Swan.

Foscolino.—On December 21st, the first screw-steamer, built to the order of the Wear Steamship Company (Limited), of which Messrs. Wrightson & Sayers are the managers, was launched from the yard of Messrs. Pickersgill, Southwick. The following are the dimensions of the vessel, which was christened the *Foscolino* by Mrs. Wrightson:—Length over all, 230 ft.; breadth, 31 ft.; depth, to floor of roof, 15 ft. 6 in.; deadweight carrying capacity, about 1,400 tons, on 15 ft. draught of water. The steamer has iron decks, topgallant forecastle, break from aft to bridge four iron bulkheads with shifting-boards complete, and water ballast tanks in fore and aft holds. She will be fitted with a steam winch to each hatchway, three in number, patent windlass, and a full outfit, including all the most recent improvements. Her engines which will be supplied by Messrs. G. Clarke, of Southwick, are to be on the compound surface condensing principle, with cylinders 27 and 50 in. diameter, and 36 in. stroke. The nominal horse power will be 100, and the effective 500, and the boilers are to work to 75 lbs. pressure.

Roxburgh.—On December 21 there was launched from Messrs. Palmer's Shipbuilding and Iron Company's (Limited) yard, at Jarrow-on-Tyne, an iron screw-steamer of the following dimensions:—Length, 290 ft.; beam, 37 ft.; depth, 24½ ft. She has been built to the order of the Caledonian Steamship Company (Limited), on the principle of cellular construction, having water ballast tanks fore and aft, forming a double bottom the whole length of the ship. She has long bridge, poop, and topgallant forecastle, four steam winches, patent steam steering gear, steam starting and reversing gear. She is to be fitted with a pair of Messrs. Palmers' surface-condensing engines, with cylinders 36 and 68, stroke 42, with large boiler power to work up to 80 lbs. pressure. Has all the latest improvements in hull and machinery, classed 100 A 1 at Lloyd's having been built under special survey. Will carry about 3,300 tons deadweight. Is intended for the American, Indian, and general trades. She is a sister ship to the *Rothesay* (s) and *Renfrew* (s), all built by Messrs. Palmers for this company.

Minard Castle.—On December 21st Messrs. Raylton Dixon & Co. launched from the Cleveland Dockyard, Middlesbrough, another steamer, which is the second they have built to the order of Messrs. Thomas Skinner & Co., of London and Glasgow, and will form one of their well known Castle Line to China. The *Minard Castle*, as the present vessel has been named, will carry nearly 4,000 tons of tea, and her dimensions are: 332 ft. extreme length, 38 ft. beam, 27 ft. 4 in. depth moulded, and about 2,600 tons gross register. Her decks, rails, and fittings, are entirely of East India teek, and her passengers will be accommodated in a deck-house aft. She is fitted with Harfield's patent steam windlass, and Bow and M'Lachlan's steam-steering gear. The engines, of 300-horse power nominal, are being constructed by Messrs. Thomas Richardson & Sons, of Hartlepool. On leaving the ways she was christened the *Miuard Castle* by Mrs. Freek.

Elk.—On December 21st there was launched from the shipbuilding yard of Messrs. Osborne, Graham & Co., Hylton, Sunderland, an iron screw steamer of the following dimensions:—Length between perpendiculars, 245 ft.; beam, 34 ft.; depth, 17 ft. The vessel is built to Lloyd's highest class, and fitted with all the latest improvements. The engines will be supplied by Messrs. Blair & Co., of Stockton; cylinders, 31 in. and 58 in. diameter, and 36 in. stroke. The steamer was named the *Elk*, and is the third vessel of similar dimensions built for the owners, Messrs. Corry, Lohden & Jacksons, of London.

Sutlej.—On December 22nd, the Peninsular and Oriental Steam Navigation Company's new steamer *Sutlej* was launched at Barrow-in-Furness. The *Sutlej*, like a sister ship, the *Ganges*, which was launched in October last, is built of steel, is of 4,100 tons gross register, and will have engines of about 5,000-horse power indicated. She is 390 ft. long; has 42 ft. beam; is 35 ft. deep, and will carry over 3,000 tons of cargo. The *Sutlej*, together with the *Ganges*, will be utilized for the India, China, and Australian mail services.

Ahdeck.—On December 22nd Messrs. Short Brothers launched from their shipbuilding yard at Pallion, Sunderland, a screw steamer, built to the order of Messrs. Walker & Butchart, Sunderland. The following were the dimensions:—Length between perpendiculars, 245 ft.· breadth, 34 ft. 6 in.; and 18 ft. 6 in. depth of hold; with a deadweight carrying capacity of 2,050 tons. She is built to Lloyd's highest class under special survey, and is constructed with a short poop for accommodation of captain, officers, &c. She has long raised quarter deck; bridge house over engine and boilers; and top-gallant forecastle, the latter comfortably fitted up for the accommodation of the crew, and the engineers are berthed in a large house on the quarter-deck. The vessel has iron decks throughout, except poop-deck. There are four large cargo hatches and steam winches, with large donkey boiler; water ballast in fore and after holds; Higginson's steam quarter-master amidships; Harfield's patent windlass, steel warps and tow-lines; with all the latest improvements for quick loading and discharging. She is to be fitted with engines and boilers of 140-horse power by the North-Eastern Marine Engineering Company, Sunderland, with all the latest improvements in marine engineering. On leaving the ways the vessel was named the *Ahdeck;* the ceremony of christening being performed by Mrs. Walker, wife of one of the managing owners.

Elginshire.—On December 22nd Messrs. Edward Withy & Co. launched from Middleton Shipyard, West Hartlepool, an iron-screw steamer of the following description:—Length b.p. 285; beam extreme, 36; depth moulded, 25·2; having a deadweight carrying capacity of about 3,000 tons. This vessel has been built to the order of Messrs. Turnbull, Martin & Co., of Glasgow, under the superintendence of their engineer, Mr. J. Wotherspoon, and is, as near as possible a duplicate of the Ross-shire (s), launched by Messrs. Edward Withby & Co., for the same firm in April last. She is built to Lloyd's highest class as a three-decked cargo-boat, with iron main and wood upper deck, and web frames in lieu of hold beams. She will be rigged as a three-masted topsail schooner, with iron pole masts, iron engine skylight, four winches, and donkey boiler, patent windlass, steam steering-gear, and double-bottom, fore and aft, on the cellular principle. On leaving the ways the steamer was named the *Elginshire*, by Miss Withy. This launch completes a total for the year of eleven steamers and 18,408 tons. All were built on the cellular principle, which reduces the gross tonnage to about 6 per cent.

Borneo.—On December 23rd Messrs. Campbell, Mackintosh, & Bowstead launched from their shipbuilding yard at Scotswood another steamer, named the *Borneo*, which is built to the order of Messrs. E. Boustead & Co., London, for Captain Ross, of Singapore, and is intended for trading in the East. Her dimensions are as follows:—Length (extreme) 190 ft.; breadth, 26 ft. 2 in.; depth, 14 ft. She is built to class 100 A 1 at Lloyd's. Her engines are by Messrs. T. Clark & Co., Elswick, and are 100 nominal and 500 effective horse power. She has three steam winches by Messrs. Clarke, Chapman, & Gurney, of Gateshead, and one of Emerson & Walker's patent windlasses. She has been built under the superintendence of Mr. Allan, the owner's engineer, and will be commanded by Captain Vincent. The christening was performed by Mrs. Allan, wife of the gentleman who had superintended the building. The vessel was most successfully launched in the presence of a number of ladies and gentlemen. The company present adjourned to the offices of the builders, where the usual toasts were proposed.

Huntingtower.—On December 23rd, the *Huntingtower*, an iron screw steamer built for Messrs. Stumore, Weston & Co.'s Tower Line, was launched from Messrs. Wigham Richardson & Co.'s yard at Low Walker, on Tyne. The extreme dimensions are:—Length, 310 ft.; breadth, 37 ft. 3 in.; depth, 29 ft. 6 in. moulded. She is classed 100 A 1 at Lloyd's under special survey, and will carry a passenger certificate; her hull, machinery, boilers, and outfit being Board of Trade survey, and to their requirements for passenger steamers. The water ballast is fitted so as to occupy none of the space in the cargo holds, which are of a cubic measurement capacity of 4,250 tons, exclusive of 250 tons of permanent bunker space. The total dead-weight carrying capacity is 3,650 tons. The frames are carried up, plated over, and decked in for a length of 80 ft. amidships, forming a protection to the engine-room and stoke-hole casings, officer's rooms, &c., in heavy weather. Steam stearing gear, is fitted in the bridge wheelhouse, and powerful screw gear in the after wheelhouse. Chadbourn's reply telegraph is fitted from the bridge to both after wheelhouse and engine room. The cargo hatches are worked by four large horizontal steam winches, and both anchors by a powerful crane and Emerson Walker's patent windlass. A saloon with accommodation for 20 first-class passengers, is fitted up in an iron deckhouse aft, and communication with the 'tween decks arranged, so that a large number of passengers could be accommodated should the ship be employed in the passenger service. The engines are compound and by the builders of the ship, diameter of cylinders 35 in. and 73 in.; stroke of piston 48 in., indicating 1,300 horse-power, and supplied by steam at 90 lbs. pressure, from two large double-ended steel boilers. This is the fifth steamer built by Messrs. Wigham Richardson, for the Tower Line, and they have three more large steamers, in different stages of construction, for the same owners, and all of which will be completed before the middle of the ensuing year.

Douglas.—On December 26th there was launched from the building-yard of Messrs. Hall, Russell, & Co., Footdee, an iron screw steamer of the following dimensions:—Length, 256 ft.; breadth, 34½ ft.; depth, 24 ft.; and 1,588 gross tonnage. The vessel, which was named the *Douglas*, and which has been built under special survey to class 100 A 1 at Lloyd's, will be fitted with compound surface-condensing engines of 240-horse-power nominal, and will have steam winches, patent steam windlass, steam steering gear, iron masts, water ballast, and all the most approved appliances for facilitating the loading and discharging of cargo. The *Douglas* has been built to the order of Messrs. Douglas, Lapraik, & Co., Shipowners, London and China, under the immediate superintendence of Captain Ashton, by whom she is to be commanded. She is specially intended for the China trade, and has accommodation for 50 first-class, 160 second-class, and 23 steerage passengers, for whose comfort and convenience admirable provision has been made. The ceremony of christening the vessel was performed by Miss Cooper, Craiglebuckler. The *Douglas* was afterwards towed to the shear-poles, for the purpose of receiving masts and machinery, &c.

Ashford.—On December 27th a screw-steamer, built to the order of the Standard Steamship Company (Limited), was launched from the shipbuilding-yard of Messrs. J. L. Thompson & Sons, North Sands, Monkwearmouth. The ceremony of christening was performed by Mrs. H. Wrightson, who named the vessel the *Ashford*. The dimensions of the steamer, which will be schooner-rigged, are as follows: Length, 275 ft.; breadth, 37 ft. 6 in.: depth, 19 ft. 6 in., and she has been built under special survey to class 100 A 1 at Lloyd's. Four hatches are provided, with a steam winch to each, patent steam windlass, steam gear, and all the latest improvements connected with the fitting of a steamer will be utilized. Mr. J. Dickinson, of the Palmer's Hill Engine Works, will fit in engines of 180-horse power nominal, with cylinders of 34-in. and 64-in. diameter, and 42-in. stroke. The boilers will bear a pressure of 80 lbs. to the square inch. This is the tenth steamer built by the firm this year.

LAUNCHES.—Scotch.

Francis Grenier.—On November 25th, Messrs. Scott & Co., Shipbuilders, Cartsdyke, launched a steamer of 308 tons burthen, for the French mail service in Cochin China. As she left the ways she was named the *Francis Grenier*. She is to be supplied with engines of 60-horse power.

Dacca.—On November 25th, Messrs. A. & J. Inglis Pointhouse, launched a steel screw-steamer of 4,100 tons, for the British India Association Line. She was named the *Dacca*, by Miss Inglis, and is the largest owned by this company. Her dimensions are—390 ft. by 43 ft. by 29 ft. to spar deck, and her engines are 3,200 indicated horse power. All the passenger accommodation is on deck, the first-class passengers being located in a midship-house about 200 ft. long, the saloon occupying the forward part. The second-class cabins are aft, also in a deckhouse, so that the entire space under the spar deck is available for coal and cargo, with the exception of the engine-room and stokers' berths. The *Dacca* is intended to sail from London for Calcutta in April next.

Remus. — On December 6th, Messrs. H. M'Intyre & Co. launched from their shipbuilding yard at Paisley the *Remus*, an iron screw steamer of 1,100 tons. The *Remus* is a sister ship to the *Mindinao*, built by Messrs. M'Intyre & Co. in August, and is for the same owner, namely, Captain Wm. Watt, Helensburgh. She is awning-decked, classed 100 A 1 at Lloyd's, and fitted out in the most complete manner as a passenger and cargo steamer, with all the latest improvements in hull and machinery. Her engines are being constructed by Messrs. Hutson & Corbett, Glasgow. The ceremony of naming was performed by Mrs. John Lochead, Row Bank, Helensburgh.

Athenian.—On December 7th, Messrs. Aitken & Mansel, launched from their premises at Whiteinch, Glasgow, the new steamship *Athenian*, built for the Union Company, and making the thirty-ninth vessel owned by that company since they began the mail service between England and the Cape Colonies in 1857. The dimensions of the *Athenian*, are as follow:—Length between perpendiculars, 365 ft.; beam, 45 ft. 6 in.; depth, 32 ft. 6 in.; and her gross estimated tonnage is about 4,000 tons. Her engines are by Messrs. John & James Thompson of Finnieston Street, the parts which have to bear the principal strain being of unusual size and weight; while the shafting is made of steel by Messrs Vickers, of Sheffield. The cylinders are 50 in. and 94 in. diameter; length of stroke, 54 in., and estimated horse-power, 3,500. The vessel is built with a double-bottom, and on the cellular system, and all the bulkheads on the main deck are fitted with massive iron doors, which are watertight and fireproof. All her boats are fitted with Hill & Clarke's patent lowering apparatus, and six of them are lifeboats, capable of carrying a large number of people. The *Athenian*, which is provided with every modern appliance for safety and comfort, is three-masted, schooner-rigged, and her masts are of iron. She will carry 150 first-class passengers, 50 second, and 120 third.

Clutha.—On December 7th, Messrs. Barr & Shearer, Ardrossan, launched a three-masted barquentine, the dimensions of which are as follows:—Length, 162 ft.; breadth, 24 ft. 6 in.; depth, 12 ft. 10 in. She is 246 tons nett register, is owned by Messrs. Munn, Newfoundland, and is intended for the Brazil trade. On leaving the ways she was named the *Clutha*, the ceremony being performed by Miss M'Call.

Siren.—On December 9th, Messrs. Barclay, Curle, & Co., launched from their yard at Whiteinch, the *Siren*, an iron sailing ship of 1,560 tons register, for Messrs. A. & J. H. Carmichael & Co., Greenock. The usual ceremony of naming was performed by Miss Arthur, Finsbury Park, London.

Mouhout.—On December 9th, Messrs. Scott & Co., Cartsdyke, Greenock, launched an iron screw steamer of 308 tons burthen, with engines of 60-horse power. On leaving the ways she was named the *Mouhout*. She is similar in every respect to the four steamers already launched by Messrs. Scott for a French firm, and she is to be employed in connection with the French mail service in Cochin China.

Rydal Fell.—On December 17th, Messrs. Murdoch & Murray launched at Port Glasgow an iron screw steamer of the following dimensions:—Length, 180 ft.; breadth of beam, 26 ft.; depth of hold, 14 ft. 3 in; of 600 tons gross. This vessel has been built for Messrs. Hume, Smith & Co., Liverpool, and is to be engaged in the Mediterranean trade. As she left the ways the ceremony of naming the steamer the *Rydal Fell* was performed by Mrs. Hume, wife of one of the owners. After the launch the vessel was towed to Glasgow, where Messrs. Dunmore & Jackson will supply her with engines of 80-horse power.

Torch.—On December 19th, Messrs. Robert Duncan & Co. launched from their yard at Port Glasgow, a twin-screw tug and tender for the Clyde Lighthouses Trustees, to be used in connection with their gasworks, for filling the buoys with gas, &c. Her dimensions are:—Length, 95 ft.; breadth of beam, 21 ft.; depth of hold, 7 ft. 6 in. Two very powerful cranes have been fitted on board. Messrs. Rankin & Blackmore, Greenock, will supply a pair of their patent disconnecting twin-screw engines of 260 indicated horse power. As she left the ways she was named the *Torch* by Miss Jennie Duncan, daughter of Mr. Robert Duncan.

Chiloe.—On December 19th Messrs. John Elder & Co. launched from their shipbuilding and engineering works at Fairfield, an iron screw steamer, built for the Pacific Steam Navigation Company, for their trade on the West Coast of South America. The vessel 320 ft. long, 37 ft. beam, 25 ft. depth of hold, and of about 2,100 tons gross. She is classed in the Liverpool Underwriters' Registry in the highest grade, and is built on the cellular double-bottom system. The engines, which are supplied by the builders of the vessel, are compound and 2,500-horse power, and are expected to drive the vessel fully 15 knots an hour on trial. The high-pressure cylinder is 42 in., and the low-pressure cylinder 80 in. diameter by 4 ft. stroke, steam being supplied by two double-ended boilers of the usual type of 100 lbs. pressure. Accommodation has been provided in the vessel for 100 first-class passengers, with the dining saloon on upper deck and on promenade deck on top. She is also fitted up for carrying cattle on deck, and has the usual steam appliances for working cargo, steering the vessel, pumping, &c. On the vessel leaving the ways she was named the *Chiloe* by Miss Mitchell, daughter of Moncrieff Mitchell, Esq., of Newmains.

Bucarest.—On December 20th the French mail steamer *Bucarest*, sister vessel to the steamers *Galatz* and *Ibrail*, recently built by Messrs. A. M'Millan & Son, Dumbarton, was launched by that firm. This vessel is to form one of the Messieurs. Fraissnet & Cie's line of mail and passenger steamers in the Mediterranean, Black Sea, and Danube, and is fitted with every comfort for passengers, and all the most superior arrangements for loading and discharging of the cargo with the utmost despatch. The *Bucarest* is 1,800 tons register, and will be furnished with engines of 1,400-horse power by Mr. D. Rowan, Glasgow.

Manapourie.—On December 20th, Messrs. Wm. Denny & Brothers launched from the Leven Shipyard, Dumbarton, the *Manapourie*, a steel crew-steamer, about 1,830 tons gross, for the Union Steamship Company of New Zealand (Limited). The name *Manapourie*, which was conferred on the vessel by Miss Denny, of Helenslee, daughter of Mr. Peter Denny, senior partner of the firm of Wm. Denny & Brothers, is of one of the numerous lakes in the province of Otago, and is adopted in pursuance of a systematic appropriation of the names of New Zealand lakes for this Company's vessels. The dimensions of the vessel are:—Length between perpendiculars, 283 ft.; breadth, moulded, 36 ft.; depth, moulded, 25 ft. She has been built of Siemens-Martin steel, under special survey of Lloyd's, and classed in their registry 100 A 1, three-decked, her bottom being constructed on the cellular and deep-floored princible and adapted for water ballast. She will be fitted for 136 first-class passengers and 117 second-class, while portable accommodation for a number of third-class passengers will be provided in 'tween decks. The vessel will be fitted by Messrs. Denny & Co. with compound surface-condensing engines of 2,000-horse power indicated, the cylinders being 41 in. and 70 in. diameter.

Orion.—On December 20th, Messrs. Caird & Co., Greenock, launched from their shipbuilding-yard a screw-steamer of 2,000 tons, for Austrian-Lloyds (Trieste), and to be employed in the China trade. Her dimensions are as follow:—Length, 340 ft.; breadth, 38 ft.; and depth, 28 ft. After the launch, the steamer, which had been named the *Orion*, was taken to the Victoria Harbour, where her engines and machinery will be put on board.

Belgravia.—On December 20th Messrs. David and William Henderson & Co. launched from their shipbuilding-yard, Meadowside, Partick, a three-decked iron screw steamer, built to the order of Messrs. Henderson Brothers, having the following dimensions:—Length, 400 ft.; breadth, 44 ft. 6 in.; depth, 33 ft.; gross tonnage, 5,000 tons. She will be supplied by the builders with engines of 1,047-horse power nominal, and will be fitted with all the latest improvements for the comfort and safety of passengers, and for the speedy loading and discharging of cargo. Accommodation has been provided in the main and 'tween decks for steerage, and on the upper deck for saloon passengers. As the vessel left the ways she was named the *Belgravia*, by Miss Clara Henderson, Westbank, Partickhill. The *Belgravia*, when completed, will be placed on the Anchor Line service between London and New York.

Austral.—On December 21st was launched from the yard of Messrs. John Elder & Co., at Govan, a screw-steamer, named the *Austral*, and intended for the Australian passenger trade of the Orient Steam Navigation Company. Her dimensions are:—Length over all, 474 ft.; breadth, 48 ft.; depth, 37 ft.; displacement, 9,500 tons. Her engines are of the three-cylinder type, capable of developing 6,300-horse power, and she is therefore expected to be very fast. Accommodation is provided on board for 120 saloon, 130 second-class, and about 300 intermediate and steerage passengers. The *Austral* is built wholly of steel, and will take the highest class at Lloyd's. She is built upon the double-bottom principle, and is divided into 13 water-tight bulkheads, 10 of which run up to the height of the main deck. Above the main deck she is divided into seven fire-proof divisions by stout steel bulkheads, and ample provision is made for a full supply of water in all parts in case of fire. The *Austral*, as compared with the *Orient*, is 10 ft. longer. of 2 ft. greater beam, and of the same depth.

Sorrento.—On December 21st, there was launched from the shipbuilding yard of Messrs. Alex. Stephen & Sons, Linthouse, Govan, an iron screw steamer of about 2,400 tons, built under special survey to class 100 A 1 in Lloyd's. This vessel forms the latest addition to the fleet of Messrs. Robert M. Sloman & Co., of Hamburg, and is for their Hamburg, London, and Australian Line. She has been fitted up with all the most recent appliances for loading and discharging cargo, and working the ship. In common with the other ships of this line, she has been provided with a meat chamber and refrigerating machinery, for the conveyance of dead meat from the Colonies. Her engines have cylinders 38 and 68 diameter, by 42 stroke, and (according to Messrs. Stephen's usual practice) were fitted on board before launching. The ship on leaving the ways, was named *Sorrento* by Miss Alice Templeton, Park Circus, and immediately thereafter was taken to the harbour to receive cargo, when she is expected to sail for Hamburg next week. The *Sorrento* is the twelfth ship which Messrs. Stephen, have built for these owners, for whom they have at present on hand two other steamers.

Quiraing.—On December 22nd, Messrs. Blackwood & Gordon, launched at Port Glasgow, a screw steamer of the following dimensions:—Length, 220 ft.; breadth of beam, 31 ft.; depth of hold, 21 ft.; and 1,250 tons gross. This steamer has been built for the Australasian Steam Navigation Company, and has accommodation for 60 first-class and 100 second-class passengers. She is brig-rigged, is supplied with a water-tank of 400 tons, has a half-length shelter deck, and is replete with all the most modern improvements. The stearing gear has been manufactured by Messrs. Bow & M'Lachlan, Paisley, and four steam winches by Messrs. Napier, Brothers, Glasgow. The engines are 200 horse-power nominal, supplied by the builders, and the steamer is expected to attain a speed of not less than 14 knots. The ceremony of naming the new vessel the *Quiraing*, was performed by Mrs. Storer, Glasgow.

Merton Hall.—On December 22nd the screw steamer, *Merton Hall* was launched from the Camperdown Shipbuilding-yard, Dundee. She is a steel steamer of 4,178 tons gross register. Her extreme length is 411 ft., or 400 ft. between perpendiculars; extreme breadth. 12 ft. 3 in.; depth of hold, 29 ft. 6 in. The *Merton Hall* has been built and engined by Messrs. Gourlay Brothers & Co., to the order of Messrs. Alexander & Radcliffe, of Liverpool, for their Hall Line of steamers, which run between Liverpool and Bombay. The *Merton Hall* will have the highest class at Lloyd's, and everything will be done to fit her for the service intended. Besides the large engines for driving the vessel, there will be eight pairs of double engines, and two single ones. These will be employed in steering the vessel, lifting the anchors and cargo, and pumping water. The steering engine will be placed far aft, so that passengers may not be disturbed by it.

Hansa.—On December 22nd Messrs. James and George Thomson launched from their yard at Clydebank a screw steamer of 700 tons, for the Hamburg-American Steam Packet Company, of Hamburg, intended to serve as a passenger tender for this company's service. The vessel, which was named *Hansa* by Miss Leitke, of Glasgow, will be supplied with engines by the builders, who are building for the same Company a magnificent liner of 5,000 tons and 5,000-horse power.

B. Kemeny.—On December 24th there was launched from Lower Yard, Dumbarton, an iron screw steamer of the following dimensions: Length, 245 ft. by 35 by 17. She has been built to the order of the Adria Steamship Company, and is fitted with all the latest improvements. As she left the ways she was named the *B. Kemeny* by Mrs. Burrell, wife of the managing owner.

LAUNCH.--GERMAN.

Deuteros.—The s. s. *Deuteros* was launched on November 26th from the yard of the Flensburg Shipbuilding Company; built to the order of the Flensburg Steam Navigation Company of 1869. She is a spar-decked vessel, and is of the following dimensions:—258 ft. by 34 ft. by 24 ft. 10 in., and will be fitted with compound engines of 160 nominal horse power. She was christened by Miss Hansen, daughter of the managing owner. She is now at the shear legs getting her engines put in, and will be finished in about four weeks.

LAUNCH.—SWEDISH.

Hoen.—On December 20th there was launched from the yard of the Motala Company at Lindholmen, a screw steamer of the following dimensions.—Length, 148 ft.; breadth, moulded, 23 ft.; Depth of hold from top of keel, 10 ft.; height between decks, 7 ft. 3 in. This vessel was named *Hoen*, and is built of Motala puddle iron and Bessemer steel; the keel, stern, sternpost, framing and plating being of puddle iron. The *Hoen* is intended for the mail and passenger route in Oresund between Denmark and Sweden, and is the seventieth vessel her owners, "Det forenede Dampskib Selskab," in Copenhagen, have afloat. She will immediately receive her engines of 100 nominal horse power.

TRIAL TRIPS.

Wandrahm (s. s.)—On November 22nd, the (s. s.) *Wandrahm* built and engined by the Flensburg Shipbuilding Company, to the order of the Steam Navigation Company, "Hansa" in Hamburg, ran her trial trip in the Flensburg Bay. The *Wandrahm* is a spar-decked vessel and is of the following dimensions:—258 ft.; by 34 ft.; by 24 ft. 10 in. and is fitted with engines of 160 nominal h. p. She is calculated to carry about 2,200 tons deadweight. She is a fine looking vessel and is splendidly fitted out with all the newest improvements. The cabin for accommodating the captain, officers, and a few passengers is placed amidships and is kept in an elegant style with polished hardwood and neat carved ornaments. The upper deck is laid with prime "East India" teakwood. At the trial everything worked to the entire satisfaction of the Owners, she obtaining a speed of 11 knots per hour.

India.—The last addition to the fleet of the British India Steam Navigation Company is a powerful steel steamer called the *India*, constructed by Messrs. William Denny & Sons, of Dumbarton. The registered tonnage of this ship is 4,065 tons, and the dimensions are:—Length, 390 ft.; breadth, 42 ft.; and depth, 31 ft. She is propelled by engines of 3,000 indicated horse power, and maintained on trial a mean speed of 14½ knots. She is divided by water-tight bulkheads. She is a flush-decked steamer, but carries the greater number of her first-class passengers in a citadel house, extending for about 140 ft. amidships, and enclosing all the vital openinings of the machinery spaces. The saloon and passengers' cabins are lighted with Swan's electric lights. In addition to the ordinary saloon, there is a music-room for ladies, a smoking and reading-room for gentlemen, and a mess-room for children and nurses, and she is provided with Gifford's refrigerating gear for the preservation of fresh meat. The *India* sailed from Gravesend for Colombo, Madras, and Calcutta, after embarking 80 cabin passengers.

Grafton (s.s.)—On December 3rd the fine new screw steamer. *Grafton*, built to the order of Messrs. F. W. Morgan & Co., London, by Mr. R. Thompson & Sons, Southwick, proceeded from this port to London, after a most satisfactory trial. The vessel, which was only launched four weeks ago, is of the following dimensions: Length, 270 ft.; breadth, 36 ft.; depth of hold, 24 ft. 6 in.; 1,150 tons net register, and 1,800 tons gross. She has been specially fitted with the most improved machinery for the East Indian carrying trade, including patent steam steering gear by Mr. C. R. Simey, of Sunderland; four steam-winches (one for each hold) by Messrs. Welford & Wigham, of Sunderland; steam or hand windlass; patent waterwitch which pumps for the hold by Messrs. Downton, patent gangways, and two steelwire hawsers of exceptional strength. She has been built on the cellular water ballast system fore and aft, and is also provided with six watertight bulkheads, which is much in excess of the average number. The boats, four in number, are fitted with Sample & Ward's patent detaching gear, by means of which they can be immediately brought into use, and the steamer is also provided with compasses of extra quality, and with Sir William Thompson's sounding machine. Intended to trade in Eastern climes, the comfort of the officers and crew has received special attention, extra ventilators having been fitted, while the berths have been made as comfortable as possible. The cabin, handsomely fitted, and berths for the captain and officers are aft, the engineers' rooms amidships, while the seamen and firemen are located in a large forecastle forward. There is also a chart house and smoke-room on deck. The engines, fitted by Mr. George Clark & Sons, Southwick, are on the compound surface-condensing principle, with cylinder of 34 in. and 64 in. diameter, 42 in. stroke, and during the trial worked up to 1,000 indicated horse-power. The *Grafton* left the dock with upwards of 2,400 tons of coals on board, having room in her hold for 300 tons more, and yet was within 1 ft. 2 in. of the Plimsoll load line. After running as far as Tynemouth, the *Grafton's* head was turned, and against a heavy wind and sea a trial of speed took place, 9½ knots being obtained, highly satisfactory considering the weather. The machinery ran very smoothly, particulary the steam steering gear, in the working of which considerable interest was evinced. It is now five years since Mr. Simey commenced his experiments, and since then he has improved upon the machine on six occasions in matters of detail, the principle always remaining the same, and the gear fitted to the *Grafton* embodies the latest improvements. It is extremely simple in construction, and most compact, owing to the rack which controls the rudder chains being worked direct upon the top of the cylinder. The advantages claimed for the machine are:—It is silent and economical, is self-draining, and owing to the moving parts being few in number and large in surface, there is practically no wear and tear. There is no vibration to affect the compasses, and should a heavy sea strike the vessel, the piston yields sufficiently to prevent breakage of chains, afterwards returning automatically to its former position. Steel-wire rope can be used in the place of chains, the machine can be started at a moment's notice, and the amount of helm given can be controlled by the officers of the watch, thus preventing over-steering. It can either be worked from the flying bridge or the main bridge, and can be disconnected for hand steering in a few seconds. The working of the gear quite bore out the claims of the inventor, and all interested in the vessel expressed themselves thoroughly satisfied with it. After luncheon had been served, Capt. Morgan proposed the health of Messrs. Thompson, Clark, and Simey, expressing his thorough satisfaction, not only with the steamer and her fittings, but also at the kindly feeling which had characterised his business relations with them. During the past ten years he had come to Sunderland for vessels, and had always been satisfied with his purchases.—Mr. W. Clark, in response, also bore testimony to the good feeling existing, and remarked that for a cargo steamer the *Grafton* would fulfil all modern requirements. He trusted that another order would soon be in hand.—Mr. C. Thompson and Mr. Simey also responded, after which "Success to the *Grafton* and her managing owners" was drunk, on the proposition of Mr. Clark, followed by the toast of "The Ladies." The company then returned to the tug, the *Grafton*, under the command of Capt. Wake, proceeding on her voyage to London, where, after discharging, she will load a general cargo for Rangoon.

Bordeaux.—On December 7th, the trial trip took place of the *Bordeaux*; built for the Company Swedish Lloyds at Gothenburg, in the yard of the Motala Company at Lindholmen, near Gothenburg. Her principal dimensions are:—Length, 200 ft.; breadth moulded, 29 ft. 6 in.; depth of hold, 23 ft. 2 in.; with a hold capacity of 72,000 cubic feet. Bunkers and all, the carrying capacity will be about 1,000 tons on the 16 feet line. During the trip the engines of 110 nominal horse power worked very satisfactorly, giving the ship a speed of 10·15 knots, with a coal consumption of 15·75 cubic feet.

Nanna.—The trial trip of this steamer, which was launched a month ago from the yard at Lindholmen, near Gothenburg, to the order of Mr. John Giertsen and others, of Bergen, Norway, took place on December 20th. When going out, the ship had a full load of wood and 40 tons of coal on board; the draught of water being 11 ft. 3 in. The engines, of 50 nominal horse power, worked well throughout; the speed attained being a little more than 8 knots with a coal consumption of 9 cubic feet. *Nanna* is of the following dimensions:—Length, 159 ft.; Breadth moulded, 27 ft. 10 in.; depth of hold, 15 ft. 6 in.; is built to class at London Lloyd's with raised quarter-deck and bridge house. This ship will be under the command of Captain H. Schjoti, and is intended for Mediterranean and Baltic trade.

Tancarville (s.)—This steamer, which was built by Messrs. Campbell, Mackintosh, & Bowstead, to the order of Mr. Cicero Brown, of Havre, went on her trial trip on December the 8th. The *Tancarville* is of the following dimensions:—Length, 293 ft.; breadth, 37·75; depth, 27·5; and can carry 3,200 tons deadweight. She is brigantine-rigged with double topsails, and is furnished with four steam winches by Messrs. Clark, Chapman, and Gurney, of Gateshead; a patent windlass by Messrs. Emerson, Walker, and Co., of London; and a steam steering apparatus by Messrs. Higginson and Co., of Liverpool. The engines are by Messrs. Thomas Clark and Co., Elswick, and are of 250 nominal and 1,300 effective horse power. The trial trip was in every respect satisfactory, and a speed of twelve knots was attained. The engines and boilers were put on board at the hydraulic crane belonging to Sir W. G. Armstrong and Co., Elswick. She was thus completely finished and ready for sea before passing the bridges at Newcastle, and it is understood she is the largest ship that has yet passed through the Swing Bridge. The *Tancarville* is commanded by Captain Pontie, and proceeded to Havre on the completion of the trial trip. She is chartered for a mail service between Canada and Brazil.

Sury Wongse.—On December 15th, the steamer *Sury Wongse*, which has been built to the order of Messrs. A. Markwald & Co., by Messrs. Wigham Richardson & Co., took place, but on account of the fog, the speed could not be very accurately ascertained. In the estimation of the Pilot she was running fully 14 knots, but, at any rate, when going under easy steam she did over 12 knots. The steamer is estimated to carry 1,175 tons on 14 ft. draught, and will be one of the fastest steamers on the China coast, where she is to trade.

Iolani.—This screw steamer went down the Clyde on her official-trip on December 14th, and attained the speed of 11 knots with ordinary working. She left for London, having been chartered by Messrs. D. Currie & Co. to go to the Cape. She has been built to the highest class at Lloyd's by Messrs. Murdoch & Murray for Messrs. Raeburn & Verel, Glasgow. Her engines, of about 170-horse power nominal, have been supplied by Messrs. Kincaid, Donald & Co., Greenock. She carries about 2,300 deadweight, and is on the three deck rule, upper deck being iron.

Sevilla.—On December 16th the new screw steamer *Sevilla*, which has been built to the order of Messrs. Henry Lamont & Co, Glasgow, by Messrs. Henry Murray & Co., Port Glasgow, went down the Firth of Clyde on a trial run, when a speed of 11¼ knots was attained. The following are the dimensions of the *Sevilla*:—190 ft. by 27 ft. by 13 ft. 11 in; her engines, of 100 nominal horse power, have been supplied by Messrs. Hutson & Corbett, Kelvinhaugh Engine Works, Glasgow. She has been built to the highest class at Lloyd's, is fitted with about 140 tons of water ballast in double bottom, and has three steam winches, and all the latest improvements. She is intended for the fruit and ore trades.

Principia.—The screw steamer *Principia*, built for Messrs. Newton Bros., of Burton-on-Trent and Hull, by the Palmer Shipbuilding & Iron Company at Jarrow, made a successful trip to sea on December 17th. This vessel is 316 ft. 6 in. in length; 33 ft. breadth of beam; 28 ft. in depth; her deadweight carrying capacity is 3,800 tons. The engines are the Palmer Company's componnd-surface condensing engines of 300-horse power nominal, the diameter of the cylinder 38 in. and 70 in. respectively, and the piston stroke 48 in.

Chittagong. - The *Chittagong* (s), which has been built by Messrs. Raylton Dixon & Co., and whose launch we noticed some little time ago, left the yard of her builders on December 21st on her first voyage, direct from Middlesbrough for Rangoon, with a cargo of steel rails. Her dimensions are:—Length, 285 ft.; breadth, 36 ft. 3 in.; depth, 23 ft. 3 in.; and her carrying capacity about 2,900 tons, having engines of 180-horse power, made by Messrs. Blair & Co. She has water ballast throughout on cellular principle, iron main and upper deck, covered with teak, cabins in poop and aft, long close bridge, and topgallant forecastle, and being built principally for the Rangoon trade, is fitted with special arrangements for loading, ventilating, and discharging rice cargoes. She is commanded by Captain M'Kirdy, late of the British Indian Steam Navigation Company's service, who has superintended her construction, and is one of her principal owners. She is owned by Messrs. P. Henderson & Co., of Glasgow.

Reviews.

The Transactions of the Institution of Naval Architects of 1881.

The number of Papers devoted to the use of Steel in Shipbuilding and boiler making, and the various remarks thrown out in discussing its merits and demerits at the Twenty-second meeting of this Institution, clearly shows the rapid strides that are being made in the introduction of steel in place of iron both for ship and boiler work.

Mr. J. D'A. Samuda, in his Paper on "The *Almirante Brown* Argentine cased-corvette, and the effect of steel hulls and steel faced armour," gave some very interesting statistics as to the saving in weight of hull by the employment of steel, and the resisting power and weight of steel-faced armour as compared with iron armour. His discourse was illustrated by some useful diagrams on the walls of the hall of the Society of Arts, which would have added to the value of the volume if made into plates, and considerably relieved the monotony of wave lines, breaking strain diagrams of crank shafts and curves of resistance, &c., &c., with which these volumes are so fully illustrated year after year.

Mr. W. Parker's Paper "On the Pecularities of Behaviour of Steel Plates supplied for the boilers of the Imperial Russian Yacht *Livadia* is a most valuable contribution to the contents of this volume.

M. Marc Berrier Fontaine, "On the use of Mild Steel for shipbuilding in the dockyards of the French Navy," gives to the Institution of English Naval Architects a good idea that our French neighbours are still inclined to hold their own in matters appertaining to high-class shipbuilding, as they were nearly a century ago, when war vessels captured from the French were always preferred by our fighting captains as much handier than vessels of our own build. The three Papers above mentioned, drew forth a large amount of discussion which, together with the valuable data given by each writer, are worth the particular study of marine engineers in any way interested in the question of steel *versus* iron.

The Papers "On the Stability of certain Merchant ships," and "On the Rolling of Sailing ships," by W. H. White, Esq., Assistant Constructor at the Admiralty, &c., are of a high class, and fully equal to any of the numerous Papers read in the past by this well known theorist.

Mr. Froude, "On the Leading Phenomena of the Wave-making Resistance of ships," displays a desire to follow in the footsteps of his lamented father in this subject. The amount of labour and patience expended on such a Paper, cannot be estimated, but will any of our leading Naval designers ever reap any benefit from these tank experiments.

With the exception of Mr. Milton's Paper "On Crank Shafts," and Mr. W. Denny's Paper "On Local Education in Naval Architecture," the remainder do not merit any special notice, with the exception that they respectively treat on various subjects in a very satisfactory manner.

Taken as a whole, this volume will compare favourably with its predecessors, although it does not in any way surpass several former issues.

It will be noticed by those who peruse the opening proceedings, that this Institution has gained in the Right Hon. the Earl of Ravensworth, a most able President, to follow the Presidency of the late Lord Hampton. It will also be seen that, the Institution is in a most thriving condition, both in point of members and funds. With the abnormal increase of new life infused during the last few years into this formerly rather lethargic Institution, their removal into rooms more becoming the character of such a Society, and the growing interest displayed in its working it, evidently bids fair to flourish and gain the position that such an Institution deserves to hold in a country whose maritime power is her greatest bulwark.

Lectures on Naval Architecture and Marine Engineering. Published by William Collins, Sons, & Co., London and Glasgow.

These lectures are a compilation of those delivered at an exhibition of naval architecture and marine engineering in Glasgow during the winter of 1880-1. This proved a most successful exhibition, and the lectures delivered during its continuance seem to have formed a most interesting theoretical addition to the practical information collected in the exhibition. No consecutive order in arrangement or choice of subject was attempted by the committee as affecting the lectures, or in the form in which the lectures are printed. The lectures are nine in all, and are on a variety of subjects. The first deals with recent improvements in naval architecture. It is by Mr. Wm. Pearce, of Messrs. John Elder & Co., and is rather a sketchy review of construction from the *Great Eastern* on to the *Livadia*. It is followed by a very detailed and exhaustive paper on the laying and repairing of submarine telegraph cables by Andrew Jamieson, C.E. The variety of routes is clearly shown in a map, the construction of the cables shown in detail; the method of laying, the operation of testing for resistance, and the process of splicing and picking up, are all clearly set forth and explained. An interesting lecture on the equivalence of heat to effect work, by Robert Mansell, Esq., of Messrs. Aitken and Mansel, and another on Lighthouses by Sir Wm. Thompson, follow.

Yachting and yacht-building is described by G. L. Watson, Esq., and the rise and progress of steam navigation, with a most interesting plate, showing the comparative sizes of leading vessels from the *Comet*, 1812, to the *City of Rome*, 1881, is set forth by W. J. Millar, Esq., C.E., in a most readable manner.

"The Resistance of Speed of Ships," by Frank P. Purvis, Esq., "The River Clyde and Harbour of Glasgow," by James Deas, Esq., and a Paper on "Steel," by Jas. Riley, of the Steel Company of Scotland, Limited, complete the book. The book thus contains in a concise form general information by the leading men of the day, on a large variety of topics all of interest to marine engineers. It is well and clearly printed, and contains many illustrations.

Naval Hygiene.—By J. D. Macdonald, M.D., F.R.S., Inspector General R N., Professor of Naval Hygiene, Army Medical School, Netley.

This work, emanating from such an authority on the special subject it deals with, cannot fail in commanding the attention of naval medical officers, captains, masters, shipowners, and all in any way interested and entrusted with the general health and well fare of British or foreign seamen. It contains a fund of amusing and instructive reading, entitling it to rank as a useful addition to any library.

In the 1st Division the Shipbuilding Retrospect, although very brief, is a most interesting description of maritime structures from the time of the Ancient Britons. The sections, detailing "Designing and then Drawing," "Construction of Wooden Ships," and the "Construction of Iron Ships," are interesting in many of their details, and are illustrated and explained in a manner which reflects great credit on the author, when the difficulty of this special subject is considered. The plans and sketches shown and explained are, in most instances, correct and instructive, although now, in nearly every instance, entirely obsolete methods of design and construction. The descriptions of the laps and butts of plates and other practical details connected with the construction of iron ships, and the remarks concerning the method of determining trim, &c., although evidently studied by the author with great care, should not attract any attention.

Chapter II., "The Ventilation of Ships." In this chapter the important subject of ventilation, with the results of many valuable experiments, is well illustrated and described. Here the author fully shows his knowledge and experience in this highly important requirement, and the whole chapter, which is by far the longest in this work, deserves the most careful reading and consideration. The remarks and data given upon atmospheric air, its physical constitution and properties, the physics of the atmosphere, and leading principles of ventilation are highly interesting to general readers, and particularly useful to all engaged in maritime pursuits. The application of special bowls and shafts, including descriptions and illustrations of methods devised and recommended by the author and other authorities on the sanitary ventilation of ships, should demand notice, and the twenty-nine analyses of the air given in Table 1, made in the three principal sleeping compartments of H.M.S. *Devastation* during her trial trips in 1873, carbonic acid being taken as the index of impurity, together with the favourable comparisons made from the results obtained as against observations made in other vessels, deserves to be fully understood and appreciated by medical naval officers and others in command, as well as by the naval architect and designer.

In Chapter III. the author again displays his special ability concerning the nature and best means of keeping up a supply of good water. In his own words, "the origin and spread of a certain class of diseases, due to the contamination of the drinking water, was long known to the Government of India, until it was decided in 1866 that competent analysts should visit the various military stations, and draw up accurate reports as to the condition of the water in use. This duty at first devolved upon civil officers, but of late years it has been conducted by military surgeons instructed in the laboratory of the Netley Medical School." Considering the great importance always to be attached to the question of the water supply amongst our troops abroad, our seamen on board ship, or the inhabitants of our numerous towns and villages at home, a perusal of the suggestions and the results of experiments, given by one who occupies a position at the head of the staff specially appointed to analyse and determine the nature and hygienic qualities and uses of water, should be most valuable and receive general attention. And the suggestions concerning the condensing, stowage, and filration of water on board ship should be studied by all naval officers, as also the instructions given in regard to ordinary and special test solutions.

Chapter IV. applies solely to the necessity of personal cleanliness, and the prevention of humidity on board ship as great beneficial factors to the health of all on board. Here the benefits of a perfect system of ventilation are peculiarly noticeable, and the remarks on the too frequent wetting of decks, and causing seamen to be two or three hours per day partly immersed in water, would convince the reader that many improvements may be made in this direction, and the health of the seaman thereby secured.

In concluding Division 1, the historical retrospect and present scale of diet, the source and mode of preparation of some of the more important articles issued to seamen, the adaptation of diet to climate, &c., and the remarks on exercise and recreation for hygienic purposes, are all valuable and of the most useful nature.

Division 2, Prophylactic Hygiene. This division should recommend itself to medical men in particular, the issue of anti-scorbutics when necessary, the issue of quinine in malarious districts, and the vaccination or re-vaccination of seamen as a prophylactic against small-pox, together with the steps taken and the orders issued by our Admiralty on each respective head, and under various circumstances, are here well explained in Sections A, B, C, and D, and Sections E to H set forth most important instructions and regulations concerning hospital ships and their arrangements as to water supply, ventilation, measurement, and allowance of cubic space, and general sanitary provisions.

Division 3, Remedial or Corrective Hygiene. This calls attention to all internal sources of disease that may exist on board ship, or such as may have been introduced from without, demanding correcting or removal. Sections A and B deal with the treatment of bilges and bilge effluvia, water closets, &c., and the uses of antiseptics, deodorants, and disinfectants, together with directions as to their composition and abstract of various experiments. Section C, in dealing with the treatment of infected ships, brings the first chapter of this division to a most useful termination.

Chapter II. of this division, if full of advice concerning the segregation of the sick on the first appearance of infectious disease, the disinfection of the bedding, clothing and effects of the sick, and modes of fumigation, with accounts of the results of particular cases.

Division 4, or appendix, is a general dissertation on the daily routine of maritime life, setting forth, amongst other duties, the special duties and responsibilities of medical officers, and giving some good forms of ambulance lifts for ships of war, the appendix of medical instructions and enactments consisting of a large list of selections from the Queen's regulations and Admiralty instructions bearing on naval hygiene (1879), carefully selected for the purpose of assistance to medical men, ships' captains and masters, army officers, &c., are most valuable for reference and information. The contents of this volume are most clearly divided and subdivided in four leading divisions and a series of chapters at the commencement, and at the finish an alphabetical index to all leading technicalities and matter will be of the greatest assistance to the reader.

Taking this work as a whole, it should command and recommend itself to the consideration and notice of Army and Navy officials, particularly the medical branches of each. It should be studied by the naval designer and constructor, and would be found to contain a large and varied amount of most interesting reading and information, rendering the book valuable to all classes of engineers and architects.

Correspondence.

[*It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.*—ED.]

ANTI-CORROSIVE AND ANTI-FOULING COMPOSITION.

To the Editor of THE MARINE ENGINEER.

DEAR SIR,—Having noticed from the recent editions of your valuable Journal, that you are taking considerable interest in Anti-fouling Compositions, I trust you will give room to a few more remarks on this subject.

You refer in your last edition to the necessity, that such compositions should possess *exfoliating qualities*.

When Anti-fouling Compositions were first brought into the market, their necessity was most felt by iron sailing ships, which, when coated with ordinary paint, sometimes turned up from a long voyage with their bottom in a most shocking state, and hardly able to move through the water. Most of these ships got their foul bottoms when becalmed, and the "parasite" in that case was the common barnacle. Now, it was found when an *exfoliating* composition was applied that, although there was nothing in the paint to *prevent* the barnacles from adhering while the ship lay becalmed, still as soon as she got under way with a stiff breeze the barnacles lost their hold, and the ship, if not too long in the water came home clean. Other compositions made on the *enamel* principle and *highly poisoned* were tried for sailing ships, but although in some instances apparently successful, they gave a poor average result, *for although they might for a time prevent the adhesion of barnacles*, still when the barnacles had once got a firm hold, they would stick to the ships "like grim death."

If, however, the proverb that "the proof of the pudding is in the eating of it," is correct, there is no doubt that these compositions have proved an entire success on *steamers*, for nearly every steamer now docking is painted with one of the many quick drying, enamel surface, and non-exfoliating compositions now in use.

These compositions derive their anti-fouling properties from *strong poisons*, of which, oxide and chloride of mercury are the most effective. Steamers are not becalmed, but get their parasites in part only. The parasites growing in the different *ports* are principally *shells* and marine grass or polypes, not *barnacles*, which only adhere on the high seas. The most dangerous are the shells, which, if they once adhere to any paint whatever it may be, get so firm a hold that they are only to be got off with chisels. I have seen a steamer, only four months before painted with tallow (a most approved exfoliator), covered with shells which had penetrated through tallow and paint and stuck hard and fast on the bare iron, although all around the tallow and red lead was in a perfect state of preservation. A strong mercurial paint, however, for a time at least, is a sure preventive of the adhesion of these shells and grass, as has been proven by the success of the different mercurial enamel paints now in use. Let me here remark that the mercurial coating must not be brought in contact with the iron, and that in all cases a coat of priming, which is usually supplied with these paints, must be used.

When so coated they prove a perfect preservative, *particularly as no exfoliation takes place*, the composition keeping its original hard surface. These compositions, usually mixed with spirits of wine or benzoline, have furthermore the advantage of quick drying, and, in consequence of their smooth enamel-like surface, offer a minimum of surface friction, thereby increasing the speed of the vessel. May I be allowed, in conclusion, to mention one of these compositions: the "International Anti-fouling Paint, which is being manufactured by Messrs. M. Holzapfel & Co., Newcastle-on-Tyne, and which possesses all the ingredients necessary to ensure its speedy adoption by all steamship owners, which furthermore on account of its cheapness can compete in price with ordinary paint.

Apologizing for so far trespassing upon your valuable space.

I am, Dear Sir,
A North-Country Ship-Owner.

December 10th, 1881.

PRESERVATION OF FOOD.

To the Editor of The Marine Engineer.

Sir,—How most efficiently to apply our existing food in the animal and vegetable forms so as always to have a surplus in hand in readiness for emergencies; to enable the speculator to store up food as well as other commodities without risk of destruction. In all articles of periodical produce, and especially in food, it will be found that fluctuations in price are greatest in proportion to the difficulty of preservation. Three conditions are essential to the process of putrefaction, viz.: heat, moisture, and still air. Without air every thing is locked up and remains in *statu quo*. In direct opposition to these principles are the granaries of Great Britain and of other countries constructed. Here the weevil is naturalized in every crevice, like cockroaches in West Indian sugar-ships, together with the existence of rats and mice as well as of germination. In the exclusion of air is to be found the remedy. The practicalization of this is neither difficult or costly; close granaries should be constructed either under or above ground of cast-iron like gasometer tanks or of brick and cement. They must be air-tight and, consequently, water-tight. A man-hole at the top is all the opening required with an air-tight cover. An air-pump is adjusted for exhausting the air, and an archimedean screw-pump for discharging the grain makes the whole apparatus complete. If we provide for wet grain a water-pump may be added, and what is good on land is also good at sea. Similar reservoirs or magazines should be constructed on a smaller scale for butchers or other provision dealers. *And so with the fish* brought to Billingsgate and other markets; thus preventing the necessity of waste, or of selling at ruinously low prices!

I am, Sir, your obedient servant,
Augustus J. Harvey, F.R.G.S.

6, Cromwell Terrace, Southtown,
Great Yarmouth, 1881.

MARINE GOVERNORS.

To the Editor of The Marine Engineer.

Sir,—Among the open questions of the day, that relating to the available room and buoyancy for cargo in screw-steamers is certainly not the least important, and correct suggestions to that end, can find no better place than in a paper like The Marine Engineer.

Taking a retrospective review of the history of screw-steamers, it will be remembered that their hulls were first constructed in accordance with the experience gained with paddlewheel steamers; but owing to the very different position and action of the screw, with the resultant blows and shocks, the vessels proved too frail, and leaks arising therefrom were of very frequent occurrence, not to speak of the many broken shafts.

Since that time, always more additional material and strength had to be given to the ships, until at present every thing possible is done in this direction, almost without regard to expense, but the consequent surplus in weight calls now for means of economy in favour of paying cargo. To this purpose steel is already largely used instead of iron; it brings about a saving in weight, to be sure, but in regard to first cost, almost the contrary.

There is, however, another and indirect way to secure economy, not only in weight, but in other directions at the same time.

Suppose the screw did work as smoothly in a rough sea as in calm weather, the former ships would have been strong enough; not being thus subjected to such fearful momentary strains, as is actually the case, when the screw is plunging again into the water while the engines are racing; consequently, those excessive reinforcements now obligatory may be in the greater part dispensed with, in so regulating the rotation of the screw, that the way described by it never exceeds the velocity of the ship plus the slip, producing absolute smoothness in the action of the screw, and saving hundreds of tons and thousands of £s. in the construction of large ships.

This is the duty of a governor, as is well known, and endeavours to produce such are indeed not missing, but the complete failure of them all for marine engines lies in the employment of an improper and impotent medium; with centrifugal force such poor results only are obtainable, that even the regulation by hand is deemed preferable: which is as unmechanical as possible, and not much better than effecting the distribution of the steam by hand.

Anything that can be performed automatically is always done with far more precision and accuracy, than the highest degree of intelligence and vigilance is capable to accomplish by hand, and so it is with the governing of steam-engines, provided the correct means are employed. The variations in their speed being dependent of the changes in the load, these latter constitute the only correct automatic agency. *The ideal governor for steam-engines is nothing else than a machine weighing accurately the resistances, and applying this measure synchronously to the direct determination of the supply of motive force.*

For its realization elasticity must be resorted to, which is by no means objectionable in any way, as for itself it is proper to prevent the destructive influence of shocks, and also in a great degree such breakdowns as are occasioned by misplaced rigidity like that between engines and screw; as an example, may be taken the effect of railway-wagons one on another if deprived of buffer-springs: every thing is smashed with a moderate concussion only.

Though the above arguments are irrefutable, said system of governors will be opposed by all people beset of prejudgment, old routine, and egotism, as it overthrows a lot of inveterate habits and accepted rules; yet it must and will break its way sooner or later, there being no small improvement in safety, and too great a saving to shipowners and insurance companies to be derived from it.

It must be admitted though, that said system is not new, but was thought fit for small powers only, and had not been brought into a really practical shape as yet, in fact, it is only by the particular position and distribution of springs, as adapted on the dynamometrical governor illustrated in last November number of The Marine Engineer, that the proper means are given at hand, to deal with thousands of horse-powers at once; combining extraordinary compactness, sensitiveness, and handiness, together with utmost solidity.

Said mechanism as a buffer-coupling, dynamometer, and governor at the same time, and with its diverse measuring and recording instruments, is sure to give unexpected satisfaction, from the largest down to the smallest scale, in spite of all imaginable criticism.

E. A. Bourry, C.E.

St. Gall, Switzerland, Dec. 17th, 1881.

To the Editor of The Marine Engineer.

Sir,—Mr. F. C. Marshall in his Paper read at Newcastle before the Mechanical Engineers says: "Mr. Perkins has shown us that boilers can be worked AT SEA with pure water, themselves making up their own waste, and can be kept absolutely clean and free from injurious deposit." Would any of your subscribers kindly explain Mr. Perkins' system, in particular, how boilers are to make up their own waste ?

I remain, Sir, your obedient Servant,
T. C. WARKMAN,
Engineer with Messrs. I. & V. Florio.

EDITORIAL NOTES.

A SAD fate seems to pursue our ironclad Navy; scientific advance but seems to increase our risks; what with incautious attendants being struck suddenly dead by electric currents accidentally diverted through their bodies, and sailors being blown to pieces by the explosion of xerotine siccative, the lives of those brought in contact with such new scientific experiments are certainly far from "happy ones" or free from risk. The details of the late fatal explosion on board H.M.S. *Triumph*, from the violent ignition of xerotine siccative are now probably well known to our readers. A leakage of the "Patent Driers" into the space between the two shells of the hull was ignited by a seaman who had no reason to imagine any explosive or dangerous substance could be there present. This occurrence has caused such strong opinion that the loss of the *Doterel* may be attributable to the same cause, that the whole subject of the *Doterel* enquiry is to be re-opened. It seems that some of the survivors are prepared to testify that only a quarter of an hour before the explosion took place, a considerable leakage of the "Patent Driers" had been discovered in the store-room immediately adjacent to the fore magazine, and further, that a man had been sent in with a light a few minutes before the explosion, probably to clear up the mess. Here is the primary explosion that has so puzzled technical minds acquainted with the circumstances satisfactorily explained. The finding of the Court, that the primary explosion arose from the ignition of gas in the coal bunkers seemed far from possible when the excellent means of ventilation is taken into account. However, the primary explosion before that of the magazine was so well established, that some such finding was a necessity, and no other known explosive substance that might have been present was then thought of. We are glad to hear that this scientific "Driers" is being got rid of as rapidly as possible over the side.

M. Lessep's Panama Canal undertaking makes but slow progress as yet. The labourers must all become acclimatized by fever as a matter of course, no doubt to their great risk at the time, and according to all reports, to their complete disorganization afterwards. This must be a serious drawback, to say the least, to the progress of the work. There is, however, a still more serious opposition threatening to the work, even when completed. The political views of the United States upon the necessity of any such canal being solely under American protection is likely to take a practical form in the organization of an opposition canal by Nicaragua. A company is now being formed in the States to carry this out, such well-known names as those of General Grant, Mr. Jewett, Mr. Ten Broeck, and Mr. Chymer, being amongst its numbers. As it is proposed that the United States shall guarantee a minimum of Three per cent. for twenty years, there will be no difficulty in such case of finding the capital. As it is an open question yet, whether the traffic would pay a suitable interest upon the cost of one canal, the construction of a rival water-way will certainly result in the non-financial success of both.

ALTHOUGH there is much and loudly expressed feeling amongst outsiders that the "Plimsoll Load Mark" is not sufficiently arbitrary against ship-owners, such loudly expressed opinions chiefly serve to show the ignorance upon the difficulties surrounding the subject of those who attempt to deal with the matter so arbitrarily. It would be either grossly unfair to the ship-owners to fix an invariable load-line to any ship for all seasons and circumstances, or else perfectly useless for purposes of protection according to whether a high or low extreme were arbitrarily fixed upon. The load-line may be well and fairly altered for every voyage. The line for August and the line for October may suitably be quite different. In the same manner, the conditions of load-line for a light or for a heavy cargo, for one that is sinkable, and for one that is unsinkable, may well vary. The present chief, and in fact very great value of Plimsoll's mark, is to register the depth to which any owner purposes to load a vessel under given circumstances. Should anything happen, the conditions stand recorded, and the responsibility may be fixed. The protection against over-loading is obvious; all arbitrary official interference must always press unfairly in many circumstances, and is entirely contrary to our system of self-government and individual responsibility. Such lines of legislation are, therefore, to be avoided if possible, and we think there is but little now to be laid to the charge of over-loading or unseaworthiness; collisions and short-handedness, with inefficient pumping apparatus, are now, to our mind, the chief defects in our mercantile Marine.

THE subject of dock accommodation, and the effect of dock accommodation, and rates on the trade of a port, is a most important one to any town claiming a position as a port. The new docks at Milford Haven promise to create a revolution in the carrying trade between England and America. The saving in distance to American trading vessels would be 174 miles as compared with Liverpool, but more important still, the dangers of St. George's Channel would be avoided. This latter danger is by no means a slight one, as it will be found from the investigation of statistics that a very large proportion of the losses in American traders have occurred in that Channel, owing to the dangers of a lee coast in the prevalent south-westerly gales. A company of powerful members has been formed already to run a new line of powerful steamers from this port. Such competition should, however, have one good effect for ship owners and merchants—it should tend to lower dock rates.

IT seems, however, that the directors of the London, East and West India Docks have not learnt the necessary consequence of competition—viz., a lowering of rates. Already London is most seriously overweighted with rates as a shipping port compared with her rivals, such as Liverpool, and with very obvious results—viz., a large divergence of shipping to the cheaper ports. Perhaps it may be startling information to some that Liverpool, with a smaller dock area than that of London, works 7½ million tons of shipping per annum, whilst London only deals with about 4½ millions of tons. And yet the London dock directors can only see their way to increasing their capital outlay, and correspondingly increasing their rates by mutual agreement. Howeve wordly wise an agreement may be amongst themselves for dealing with what shipping is obliged to come to London, the ultimate effect upon the shipping trade of London as a port cannot be otherwise than most disastrous. If the vast sums expended on the London docks and works are now unsuitable for the traffic, and fresh works must be put in hand in a more advantageou situation, surely the directors know the first principle of business to "cut a loss," whilst it is bearable, rather than throw good money after bad. The construction of new docks at Tilbury will certainly do much for London as a port and for its shipping trade, but a prohibitive rate put on to bolster up a former speculation, now found to be antiquated, and somewhat of a commercial failure, will only serve to damn the whole.

SOME time ago we drew attention to an experiment that was to be tried with oil used as means of reducing the breaking of waves into harbours and anchorages. The project may have seemed somewhat visionary to sceptical minds, but the results seem to give practical importance to the system. The experiment has been carried out at Peterhead, the supply of oil being distributed by pumping through perforated pipes throughout the harbour. The result of the trial was considered highly satisfactory, waves of considerable height were rolling in and breaking as soon as they entered the narrow space between the headlands of the harbour's mouth. After pumping for half an hour the whole expanse of the harbour was covered with oil, and the waves, on nearing the harbour, became mere gentle undulations, whilst they ceased to break at all. Perhaps, in a few years to come, oil may become an acknowledged means for aid in stilling the waves in case of shipwreck and violent seas, and be discharged from the shore or from the vessel itself.

NOTICE.—Owing to great pressure on our space, we are obliged to hold over the article on "Ocean Steamship Machinery" until our next issue.—ED. M.E.

THE NEW SCREW STEAMER "MERTON HALL."

THE screw steamer *Merton Hall* (see double-page illustration in this number), which was launched on December 22nd, is a steel steamer of 4,178 tons gross register, and is the largest vessel yet built in Dundee or the east of Scotland. Her extreme length is 411 feet, or 400 feet between perpendiculars; extreme breadth, 42 feet 3 inches; depth of hold, 29 feet 6 inches. The *Merton Hall* has been built and engined by Messrs. Gourlay Brothers & Co., to the order of Messrs. Alexander & Radcliffe, of Liverpool, for their Hall Line of steamers, which run between Liverpool and Bombay. The Hall Liners do not carry a large number of passengers, but very comfortable quarters are provided for twenty-four first-class passengers in a house on deck; and as the *Merton Hall* will have a good rate of speed, her cabins will, no doubt, be well filled—as indeed those of this line generally are. The rigging plan shows that the *Merton Hall* will have four masts—two square-rigged, and two with fore and aft canvas. The fore part of the vessel will be protected by a forecastle of turtleback shape. The engine and boiler spaces, which are of vital importance, are entirely covered, and there is a hood aft to protect the wheel and prevent water being shipped over the stern. The bulwarks are partly close and partly open; they are close where the sea is most likely to break on board, and open where it can best get clear, so that no great quantity of water can ever remain on deck. From the longitudinal section it will be seen that the vessel has three decks; these are of steel, and will give great longitudinal and transverse strength. The cabin is placed nearly amidships, and forward of the engines and boilers, so that the passengers will be free from the disagreeable accompaniments of moving machinery. The officers' berths are placed amidships alongside the engines and boilers, and are of the most comfortable character. The engines which are to be fitted on board the *Merton Hall* are to be high and low pressure and surface-condensing, of four hundred and sixty nominal, or two thousand five hundred effective horse-power. The cylinders are respectively forty-five and eighty-four inches diameter; and the length of stroke five feet. The pressure of steam is to be 80 lbs. per square inch, and will be supplied by three double-ended boilers having fourteen corrugated steel furnaces. The *Merton Hall* will have the highest class at Lloyd's, and everything will be done to fit her for the service intended. Besides the large engines for driving the vessel, there will be eight pairs of double engines and two single ones. These will be employed in steering the vessel, lifting the anchors and cargo, and pumping water. The steering engine will be placed far aft, so that passengers may not be disturbed by it.

NOTES RELATING TO THE PROPER METHOD OF EXPANSION OF STEAM AND REGULATION OF THE ENGINE.

By PROF. R. H. THURSTON.

Read before the American Society of Mechanical Engineers, Altoona Meeting, August, 1881.

IT has long been well known, to every engineer experienced in the construction and management of the steam-engine, that, when working under known conditions and at a given pressure of steam, there is a certain ratio of expansion which gives highest efficiency, *i.e.*, least expenditure of fuel in proportion to work done. It has also been long known that the most economical ratio of expansion, all things considered, when studied from the commercial standpoint, is to be determined not simply by studying those conditions which affect the efficiency of the engine, but by consideration of all the elements of cost of steam power, including first cost, interest on capital expended, wear and tear, and running expenses for fuel supply and management.

In the design of an engine it thus becomes necessary, if the designer would consult the best interests of the purchaser of the engine, first to determine, as best he can, what is likely to be the cost of each series of engines of the style proposed and of graded sizes; next must be determined the cost of power in weight of steam used in each of these engines at various pressures and ratios of expansion; finally, by comparison, he must select that engine which, at the least ratio of expansion, all things considered, will give the required power.

When the steam pressure and the cost of power in steam consumption are known, it becomes possible to determine the best point of cut-off. But no engineer has yet been able to say with certainty what, in any given case, will be the ratio of expansion giving highest efficiency, or, what, at any given rate, will be the probable expenditure of steam or fuel. The writer has endeavoured, in an earlier paper,* to show what are the causes of this uncertainty, what determines the most efficient adjustment of expansion, and what, on the whole, have, in his judgment, proved to be the ratios of expansion giving maximum efficiency, and, finally, what efficiency may probably be anticipated in cost of steam and of fuel in good engines, adjusted for maximum efficiency.

When these points are settled, the engineer may, by a proper use of the factors, ascertained as above indicated, determine what is the best ratio of expansion to adopt, or rather what is the best size of engine for the case in hand, and what the best type of valve gear and regulating mechanism. The size and kind of engines is therefore determinable from a knowledge of conditions, which are partly physical and incidental to construction, and partly commercial.

The solution of this second and broader problem may be effected either by a tentative process of trial and repeated estimation, or by an approximate, and for some cases—*e.g.*. where cylinder condensation is reduced to a minimum, as in efficiently jacketed or in fast-moving engines, or at low rates of expansion—nearly exact method, first indicated, so far as the writer is aware, by Professor Rankine,† who applies to the case one of those beautiful graphical constructions in the devising of which he was so ingenious and successful.

This method has been studied and has been applied to representative examples in recent practice in steam engineering by Messrs. Wolff & Denton,‡ who have shown that the commercially profitable grades of expansion are ordinarily restricted to a very narrow range, and always somewhat less than the ratio for maximum efficiency.

Having, then, fixed upon the size of engine and ratio of expansion, it is evident that this ratio of expansion should generally be kept invariable, so long as the steam pressure remains unchanged.

The usual changeable condition with a given engine is the demand for power, and, to meet this variation, it becomes necessary to adopt some method of regulation. The simplest forms of regulating apparatus usually consist of a "fly-ball" governor set engines is that adopted by Corliss—the attachment of the governor to the expansion gear in such a manner as to cause a variation of the ratio of expansion, adjusting the point of cut-off to the demand for power. This latter is the most sensitive regulating mechanism yet devised, and, where the variation is small, is very effective even at low speeds. The writer has counted the revolutions of a Corliss engine making about sixty revolutions per minute, with steam at 90 lbs. by gauge (7 atmospheres), and found a variation of but two revolutions per minute when the whole load was thrown off or on, the minimum being about 35 horse-power (driving shafting) and the maximum about 150.

* "On the Ratio of Expansion at Maximum Efficiency," Trans. Am. Soc. Mech. Engrs., 1881; Journal Frank. Inst., May, 1881.

† Phil. Magazine; Trans. R. S. E.; Theory and Practice of Shipbuilding; Miscellaneous Papers.

‡ Trans. Am. Soc. Mech. Engr's., 1881; The American Engineer, 1881.

Since, however, the proper ratio of expansion for the engine when once installed is determined mainly by the steam pressure, and since any variation from that point is usually productive of reduction of efficiency, it would seem that the ratio should be fixed at the best proportion for the steam pressure adopted and never changed. This being the case, the question arises, how shall regulation be effected? The adjustment of a throttle-valve by the governor is inadmissible, as it involves variation of the steam pressure in the steam chest, and consequently reduced efficiency; the steam and expansion lines must be permanently fixed for all loads.

It becomes at once evident that any allowable system of regulation must now affect the back pressure or the cushion line. To throttle the exhaust by the action of the governor would undoubtedly give a means of regulation, but a costly one; since any increase of back pressure during the exhaust would involve serious increase in the amount of rejected heat and of waste of power.

It then becomes evident that the only admissible plan is the variation of the net power of the engine by an alteration of the compression line. This is done where one very well known and generally used valve gear is adopted—the Stephenson Link Motion. When the link is down the ratio of expansion is determined by the lap and lead, and is usually not higher than $\frac{1}{2}$; as the link is raised this ratio is increased, and with this change of the steam line occurs a simultaneous alteration of the point of release and of closure of the exhaust passages, resulting in increased compression. This double effect gives the indicator diagram a peculiar modification of form, familiar to engineers who have taken cards from the locomotive or the usual type of marine engine. The smoothness of working of such engines, when running with high steam and a raised link, has probably been observed by all experienced engineers, and it may not have escaped notice that, under such conditions, the expenditure of steam is often so low as to indicate some source of economy other than simple change in the ratio of expansion.

The writer, at least, when in charge of naval steam machinery during the war of 1861-5, was led to suspect a gain from this distribution of steam, which could only be attributed to what was considered excessive compression.

His attention has recently been called to this matter again by the interesting results of a series of experiments made upon a large engine fitted with variable expansion gear. The valve motion is so arranged as to permit adjustment of compression without change of either steam, expansion, or exhaust lines. The results will be reported in a later paper. It is only necessary here to state that a decided gain is found to follow the adjustment of the compression to a far higher ratio than is indicated as best by the simple geometrical conditions usually studied and generally taken as those determining the proper ratio of compression. This beneficial effect of a high ratio of compression has been attributed by the writer to the action of the compressed fluid in heating the passages and the cylinder head and piston, thus checking to a very great extent that initial cylinder condensation which is the greatest source of avoidable waste in nearly all engines.

It may be asserted that the best compression, where no such transfer of heat occurs, is not far from that which makes the ratios of expansion and compression equal, and the engineer will usually set the exhaust valve to close at the point corresponding to maximum expansion. For the reasons just given, however, and as shown by direct experiment, maximum efficiency is obtained with higher ratios of compression, and what would have been considered excessive cushioning gives less loss than equal variation from the point of cut-off giving maximum efficiency. As compression is increased, the area of the indicator diagram decreases and the work developed in the engine becomes less.

It would seem, then, that we have here an admissible method of regulation, and one which should be, on the whole, that best fitted to give high efficiency, since any excess of work of compression results simply in the transfer of heat back to the steam side. The steam engine should, therefore, be worked with a fixed cut-off,* so attaching the governor as to determine the point of closing of the exhaust valve—in other words, making the "cut-off" operate on the exhaust side, the ratio of compression being determined by the governor—instead of attaching the cut-off mechanism to the steam valves. Properly constructed relief valves will prevent all danger from the influx of water with the steam, an accident which, however, should never occur where provision is made for securing dry steam. With exhaust ports beneath the cylinder, drainage is rarely imperfect.

In slowly moving pumping engines it has sometimes been found beneficial to extend compression until boiler pressure is exceeded, and the writer has indicator diagrams taken from such engines in which the compression line crosses the steam line before the end of the return stroke has been reached. He has, as probably has every engineer who has been accustomed to handle locomotive or marine engines, often set the link motion so as to give such high ratios of expansion and compression as to reduce the card to a comparatively narrow band, without perceiving the slightest evidence of objectionable loss of smoothness of working and with decidedly improved efficiency. It seems to the writer doubtful whether, in practice, objectionable or "excessive" compression ever occurs in such cases, and the advantages of this method of regulation and of securing a lessened variability in the ratio of expansion would appear to be decided and to be obtainable without meeting with serious difficulties.

The plan is probably not entirely a novel one and may have suggested itself to many engineers independently; but no attempt has previously, so far as the writer is aware, been made to determine its advantages in actual work. The writer indicated this as the proper method of adjusting expansion some years ago,† and has since had it presented to him by other engineers with whom the thought was also original.

Where the plan here suggested cannot be adopted conveniently maximum economy of steam should be obtained by an expansion, gear in which as in locomotive valve gear, increased expansion is accompanied by increased compression, but without that serious throttling along the steam line which usually characterizes the distribution by the link-motion.

The best among existing forms of valve gear should be, if judged from the standpoint here taken, that which—combining a variable expansion with a variable compression—is also capable of prompt and exact adjustment by a sensitive and efficient governor.

The economy to be expected from the suggested change in methods of regulation of the steam engine will evidently be dependent upon the manner of operation of the engine. Where engines have a nearly invariable load, and when they are well adjusted to their work, the advantage would probably be found inappreciable; but in cases in which the engine is much too large for its work or when the demand for power is very irregular, as in rolling mills or in rough weather at sea, and where cylinder condensation occurs to a great extent, the increased efficiency may be found to be very considerable. The gain by decreased internal condensation will, perhaps, often be found to be an item of no small importance.

Shipbuilding in Barrow.—The following is a list of the vessels launched from the Barrow Shipbuilding Yard, Barrow-in-Furness, during the year just past:—*City of Rome*, 8,500 tons; *Lismore*, 4,200; *Navarre*, 4,200; *Strabo*, 2,000; *Bearn*, 4,200; *Dredger*, 500; *Ganges*, 4,200; *Sutlej*, 4,200; *Rossall*, 200; and *Fenella*, 500; making a total of 32,700 tons.

An electric log has been invented by Mr. C. E. Kelway, and is known as the "Kelway Electric Log." The rotation of the log screw is made to complete an electric circuit a given number of times (regulated by the number of teeth in a ratchet wheel placed on the "mile" spindle of the log) in a mile, which, as now arranged, amounts to eight. At each completion of the circuit a current of electricity passes through the coils of a step-by-step counter, which forms the dial similar to a clock face. This dial being placed in the chart-room, captain's or engineer's cabin (or a dial may be placed in each, and worked from the same log), the distance run can be read off at any moment, and the actual speed of the ship known at will.

---

* The writer has devised methods of automatic readjustment of the ratio of expansion when variations occur in the steam pressure, which methods would, in the case here taken, replace the usual adjustment by the governor

THE EADS' SHIP RAILWAY.

THE question of giving substantial support to the project for transporting large vessels by rail across the Isthmus of Tehuantepec, according to the plan advocated by Captain Eads, will shortly again engage the attention of the Congress of the United States of America.

As our readers are well aware, the idea of reaching the East by way of the West has long been a prevailing one in the minds of both navigators and traders, and the actual suggestion of a ship railroad dates back to the time of Cortez, in the early part of the sixteenth century. In the year 1814, Spain, after prolonged consideration, gave the project her consent, and authorized the construction of a railway. The scheme, however, lapsed, and since then, notwithstanding that the United States Government was prepared to pay fifteen million dollars for right of way, nothing further has been done.

More recently surveys have been made on several different occasions, for the purpose of determining the practicability of constructing a canal, and it really seems as if the actual commencement of the canal through the Isthmus of Panama had at last awakened the Mexican Government to take definite and decisive steps.

The Isthmus of Tehuantepec is situated at the extreme south of Mexico, about 1,200 miles north-west of the tract of the proposed Panama Canal, and at its narrowest part is 143 miles wide. As here the mountain ranges interpose no special obstacle, the Sierra Madre at three different points attaining only a height of about 650 feet, this locality has been selected by the projector as the one offering the fewest difficulties in the carrying out of his work.

The ship railway of Captain Eads is designed on precisely the same principle as the ordinary shipways for repairing vessels; only, as the speed of transit is intended to be much greater than the rate of hauling usually adopted at shipways, both the cradle and ways will necessarily be somewhat modified in strength and construction. The cradle is to be of wrought iron, about 300 feet long, with 1,200 wheels, running upon 12 lines of rails, the total load per wheel being not more than 5 tons when conveying a vessel weighing 4,000 tons. The rails are to be of steel of the usual railway section, laid at slopes of from 1 in 100 to 1 in 30, and they are to be carried into the water at each end, at such inclination and to such distance as to afford sufficient depth for readily floating vessels over the cradle.

When a ship is to be taken up, the cradle will be run down to the desired depth in the water by its own weight and the vessel guided into position by ropes carried to capstans on piers at either side. The cradle will then be gradually hauled up the incline by stationary engines, the ship all the time settling down on bilge and other blocks provided to receive it. So soon as it is fairly out of the water, two pairs of specially powerful locomotives will be attached, and will transport the cradle, with its load, across the isthmus to the other side, where the vessel will be immediately launched into the water and be ready to resume its voyage without further delay or loss of time. There will of necessity be no curves in the track, changes of direction being accomplished by turntables; and it is expected that the whole distance of 143 miles will be traversed in about 12 hours. This time, however, need not be lost, for, the moment the vessel is out of the water, gangs of cleaners and painters may be set to work on the hull. and any light repairs, either to the vessel or to the machinery, may be carried out during the journey.

From this slight description it will be seen that the engineering difficulties are not such as are likely to place any great obstacle in the way of the successful carrying out of the undertaking, providing the site has been selected with care. Great strength must, of course, be provided, and great stability of ways. With this, and careful proportioning of parts, the matter merely resolves itself into the construction of six lines of ordinary railway side by side, having one large truck common to all. That the ship, if properly secured, is not likely to sustain any injury, is obvious, when it is remembered that Lloyd's rules require every sea-going vessel to be so strong as to be capable of being supported on a single bearing at the centre of its length, or between two supports at its ends, without being strained in any part beyond limits of safety.

The concession which the Mexican Government has granted to Captain Eads is a liberal one, and the terms are such as will probably enable him to engage the patronage and assistance of the United States Government. This is the question which is shortly to be submitted to Congress, though if, as is stated, a rebate in the transit dues will be made to all United States ships, so as to allow them to compete on more favourable terms against English carrying vessels, it is highly probable some arrangement will be come to. On the other hand, however, if the railway is to be a commercial success it will have to be kept in view that American vessels paying reduced dues are not likely to provide dividends for the shareholders, who, if they are to be dependent upon foreign, and especially British, ships for support, would find that, in the long run, it would be more to their advantage to offer them inducements instead of attempting to make them pay for the transit of United States vessels by imposing increased dues.

The period for construction of the work is put down at about five years, and the total estimated cost at seventy-five million dollars, or, at the rate of half a million dollars per mile; figures which, from their great magnitude, render it extremely important that the commercial aspect of the scheme should be thoroughly well considered. To the British shipowner any safe method of expediting and shortening the voyage to the far East must be welcomed, provided the advantage be not counterbalanced by a much increased cost; but, with the rapid strides now being made in regard to the sizes of steam vessels in this country, we would point out that a total weight of vessel and cargo of 4,000 tons, which, we believe, is what the projectors intend providing for, is not nearly sufficient. If our carrying is to be done by the large ships. such as are now being built for our principal lines, 6,000 tons, or even more, will be reached; and, if capacity for this weight is not given, we very much fear that, by the time the railway is opened, it will be quite useless for the conveyance of our principal traffic.

INSTITUTION OF CIVIL ENGINEERS.

SIR W. ARMSTRONG ON NATIONAL DEFENCE.

AT the ordinary meeting on Tuesday, the 10th of January, Sir W. G. Armstrong, C.B., F.R.S., delivered an inaugural address as President.

He observed that it had been the practice of his predecessors in the chair, to select topics for their address that had reference to branches of engineering which operated to increase the productiveness of human industry, and there were many who would contend that all engineering efforts ought to centre upon that object. It might be fully admitted that the general amelioration of the material condition of the world was the noblest object of engineering science; and if men and nations ceased to be bellicose and rapacious, such would naturally be the direction which all engineering practice would take; but this was a world of contention, where no individual state could insure its independence, and carry on its industrial occupations in safety, without protecting itself against the possible aggression of its neighbours. Thus it was that the science of the engineer was invoked for the purposes of war as well as for those of peace; and it was probable that the engineering element would in future enter more and more largely into the operations of war, until the issue would be chiefly dependent upon the superiority of mechanical resource displayed by one or other of the contending parties. There was no country in the world less disposed to be aggressive than our own, but there was none so likely to incite the greed of an assailant, or so vulnerable in relation to its commerce. War indemnities had degenerated into mere exactions proportioned to the wealth of the vanquished; and England, being the richest of nations, offered the highest premium for successful attack. As to commerce, England had more than one-half of the ocean carrying trade of the whole world in her hands, and her ships, swarming over every sea and conveying merchandise of enormous value, would, in the event of war, invite the depredations of hostile cruisers. We had seen in recent years what ravages a single-armed ship could inflict upon a mercantile navy incomparably smaller than our own, and, in our case, it was not only property, but indispensable food that was at stake. The ever-increasing population of Great Britain had already far outgrown its internal means of support, while the increasing cheapness of imported food so discouraged native agriculture, that we might expect our future dependence upon foreign supply to increase even more rapidly than our population. This was not the occasion to discuss either moral questions affecting war, or political questions concerning free trade. We had the stern fact before us that national defence was in our case peculiarly a necessity, and the question how it could best be effected, from an engineer's point of view, was a legitimate subject for this address.

England must always be chiefly dependent for security upon her naval power, but we could not hope that she would ever again be so dominant at sea as before the introduction of steam navigation. So long as naval superiority depended upon seamanship and an unlimited supply of sailors, no nation or combination of nations could compete with us; but as soon as it became established that fighting ships could be manœuvred with more certainty and precision by the power of steam than by the power of wind, a revolution began which had gradually made naval warfare a matter of engineering rather than of seamanship. The introduction of rifled ordnance and percussion shells was the second step in this revolution, and had the effect of condemning as useless the whole fleet of wooden ships with which all our victories had been won, and which were the pride of the nation. Then commenced that contest between guns and armour which had gone on to this day, and had not yet been decided. Nor would it, in all probability, ever be decided, seeing what an *ignis fatuus* finality was. The most recent stage of this revolution was that marked by the introduction of torpedoes, against which our ponderous ironclads were no more secure than ships of thinnest iron. These constantly-changing phases of attack and defence had placed our naval authorities under extreme difficulty in deciding upon questions of ships and armament. To stand still was impossible, while to act upon uncertain data was sure to lead to mistake. The necessary consequence had been that types and patterns of ships had been continually changing, and vessels, costing vast sums of money, had become nearly obsolete almost as soon as made. We could not wonder that, so long as invulnerability was conceived to be attainable, great sacrifice should be made for its accomplishment; but with our present knowledge, which it would be unfair to apply to a criticism of the past, we might feel assured that invulnerability was a chimera. Not only did we see that armour was unavailing against torpedo attack and ramming, but we were justified in concluding that every attempt to increase resistance to projectiles would be quickly followed by a corresponding increase in the power of artillery. Our early ironclads, like the Warrior, were plated all over with armour 4½ in. thick—a thickness which could now be pierced with field-pieces. To resist the most powerful guns now afloat, armour of at least 2 ft. in thickness was required; and in order to reconcile the constantly increasing thickness with the weight which the ship was capable of carrying, it had been necessary to restrict the area of armoured surface to ever narrowing limits, leaving a large portion of the ship without protection. In those magnificent and tremendous vessels which the Italians were now building, the armour would be withdrawn from every part except the battery, where guns of 100 tons would be placed, and where the armour would be confined to a narrow belt of great thickness. Everything of importance that projectiles could destroy would be kept below water-level, and, so far as artillery fire was concerned, the ships would be secured against sinking by means of an under-water deck and ample division into compartments. Armour therefore seemed gradually contracting to the vanishing point; but, until it actually disappeared, it was probable that no better application of it could be made than had been decided upon by the acute and enterprising naval authorities of Italy for the great ships they were now constructing.

The dread of the terrible effects of the fragments of shells bursting amidst a crowded crew, and the apprehension that the smoke from the explosion, when it occurred between decks, would paralyse the service of the guns, had conduced more than anything else to the adoption of armour. Methods of avoiding or lessening these dangers, otherwise than by the use of armour, had been little considered; yet the alarming aspect of the case was greatly altered when we reflected that, by the application of mechanical power, to do what had hitherto been done by a multitude of hands the exposure of a crowded crew could be avoided, and also that the guns might all be mounted on an open deck, where the smoke from shells would speedily clear away.

As to the comparative liability of an ironclad and an unarmoured ship to be sunk by projectiles, there was much less difference between them than was generally supposed; because the unarmoured ship, though freely penetrable, might be so constructed that the entrance of water by perforation would not extensively flood the ship, unless it took place at a great number of critical places. Indeed, by introducing an underwater deck, with divisional spaces, and by the partial application of cork, as in the *Inflexible*, for displacing influent water, and thereby preserving stability, and also by a proper distribution of coal for the same purpose, an unarmoured ship might be rendered almost incapable of being sunk; and it was rather surprising that so little attention had been directed to the attainment of that object.

It was not too much to say that, for the cost of one ironclad, we could have three unarmoured ships of far higher speed and carrying collectively three armaments, each equal to that of the armoured vessel. It might be asked, Which would be the better investment? If it were imagined that the three were matched in combat against the one, it would be perceived that, in addition to their numerical superiority, the former would possess many advantages. Being smaller, they would be more difficult to hit. Being swifter, they could choose their positions, and be free to attack or retreat at pleasure. Being more nimble in turning, they would be better adapted both for ramming and for evading the ram of their adversary. Finally, the conditions of superior speed and agility would favour their use of torpedoes and submarine projectiles; although it was a question whether, for the sake of a much-needed simplification, it would not be better to confine that species of attack to separate vessels specially constructed for that one particular purpose. Even if the utmost advantage she could possess were conceded to the ironclad, viz., that of being impenetrable by the guns of her opponents—she could not prevail in a contest of three against one, unless, by the use of securely-protected artillery, she could keep her assailants at bay, and gradually destroy them by her fire if they persisted in their attack. Such might be the issue if the allied vessels had nothing but guns to oppose to guns; but they would naturally, under such circumstances, place their men below, out of the reach of projectiles, and then attack with their rams or torpedoes. With the crews in safety, it was scarcely possible that unarmoured vessels, with under-water decks and all their machinery beneath, should suffer any disabling injury by being pierced in a few places by either shot or shell. But, take the much more probable alternative of the armoured vessel being penetrable by the guns which would be used against her. In that case her enemies might elect to make the contest one of artillery. On their part, armour-piercing projectiles would be used which, on penetrating the thick sides of the ironclad, would carry inboard a mass of broken material far larger in quantity than the fragments of the shells with which they would be assailed, and quite as destructive in effect. The ironclad would have to sustain the converging fire of three ships, each carrying the same armament as her own, and her swift and nimble adversaries would steam round and round her, directing their fire on the most vulnerable points, and ever ready to seize a favourable moment to dash in and finish the contest by ramming. In either case, therefore, the ironclad would be overmatched by a combination of unarmoured vessels representing the same pecuniary value. Without entering into technical questions concerning fleet-fighting, it seemed reasonable to believe that the result would be the same if the number engaged on each side were proportionately multiplied. Inferiority of speed and of number would still give the choice of position, and secure the advantage of converging fire; besides which, the greater power of division and of concentration must always belong to the more numerous fleet. But, if ironclads were not needed for the purpose of opposing ironclads, it was difficult to see for what purpose they were wanted at all. For every other kind of service, a numerous fleet of smaller and swifter vessels, unencumbered with armour, would clearly be preferable. To protect our commerce, to guard our extensive seaboard against invading flotillas, to lend naval assistance to our colonies in case of need, and generally to maintain our supremacy at sea, we required a far more numerous navy than we possessed or could afford to possess unless we vastly reduced our expenditure on individual ships, and to do this we must dispense with armour. It might, perhaps, be rash entirely to abandon armour so long as other nations continued to use it, because nothing but the experience of an actual war would remove all question as to its possible utility; but, considering the indisputable value of a numerous fleet of swift and powerfully-armed ships, built with a view of obtaining the maximum amount of unarmoured defence, and, considering that such vessels, unlike armour-clads, could never grow much out of date, it did seem to be expedient that the chief expenditure of this country should be upon ships of that description. Lightness should be the special aim in the construction of such vessels. Steel plates should be used for the hulls, and guns and engines should be of the least possible weight consistent with the necessary power. Every ton of weight saved would enable higher speed to be attained, and there was probably no quality in a fighting ship which would so much develop in importance as that of swiftness. Messrs. Thornycroft has led the way in showing what extraordinary speed could be realised in diminutive vessels, by reducing to the utmost the weight of every part of the structure and its contents; and, although we could not expect to attain proportionate speed by the same method in ocean-going ships of war, yet there could be no question that we might have far swifter ships than at present if lightness were made the principal object, instead of the prevalent practice of loading ships with cumbrous armour, in the vain hope of rendering them invulnerable. Light unarmoured ships, designed by Mr. George Rendel, had lately been built in this country for foreign powers, which, with a displacement of only 1,300 tons, had attained a speed of 16 knots an hour. They carried coal for steaming 4,000 miles, and had already actually steamed 3,500 miles without replenishing. They were each armed with two 10-in. new-type guns, which had nearly an all-round fire, and were capable of piercing 18 in. of iron amour; and with four 40-pounders on the broadsides. It was a very serious question what could be done in the event of a number of such vessels as these being let loose upon our commerce. At present there was not a single ship in the British navy carrying an armament competent to engage them, that could overtake them in pursuit, or evade their attack when prudence dictated a retreat. Confidence was often expressed in our mercantile marine being capable of furnishing, on an emergency, a supply of vessels fit to be converted into cruisers; but where were there to be found amongst trading or passenger steamers, vessels possessing a speed of 16 knots, with engines and boilers below water-level, and having an under-water deck to save them from sinking when penetrated by projectiles at or below the water-line? From his own experience he knew how difficult it was to adapt mercantile vessels to the purposes of war, and how unsatisfactory they were when the best had been made of them. It was alarming to think how unprepared we were to repress the ravages which even a small number of swift marauding vessels, properly constructed and armed for their purpose, could inflict upon the enormous property we had at all times afloat, and how little we could hope to clear the sea of such destructive enemies, by cruisers improvised out of ready-made steamers destitute of all the conditions necessary to render them efficient for such a service. It must ever be borne in mind that it was not merely the loss of property and interruption of trade that we had to fear, but also the interception of food supplies; and that the more our population increased and our agriculture declined, the more terribly effective for reducing us to submission, would be the stoppage of those supplies.

The President then adverted to harbour defence. He pointed out that many of our ironclad forts had already outlived the stage of artillery progress for which they were adapted. He expressed his opinion as to the best method of rendering large guns effective in shore batteries. He dwelt upon the value of gun-boats, considered as floating gun-carriages, and used in combination with torpedo craft and submarine mines; all of which, he suggested, might be committed to the management of trained naval and engineer volunteers resident on the spot.

He said it would be a grand development of the volunteer movement, of which this country was so justly proud, if it were thus to be extended to harbour defence; and he was informed that, so far as the use of submerged torpedoes was concerned, a project of intrusting their employment to a corps of volunteer engineers was already under consideration. The superior education and intelligence of the class from which our volunteers were mostly supplied would especially fit them for the discharge of duties involving skill and discretion, such as would be required in the handling of electrical apparatus, and we might be sure that, wherever dash was needed in the use of torpedo boats, there would be no lack of that quality amongst volunteers in the hour of trial.

On the subject of artillery, he described the progress of gun manufacture since the introduction of rifled ordnance, prior to which a gun was simply a tube of cast iron or bronze closed at one end. He also discussed the question, what, under the present conditions and prospects of steel manufacture, should be our practice as to the use of that material for artillery purposes. He was then led to speak of a system of construction which had not passed through the experimental stage, but which, from the results it had already given, promised to attain a wide application. He referred to that system in which the coils surrounding the central tube consisted of steel wire, or ribbons of steel, wound spirally upon the tube. To those who objected to welded coil tubes on the ground of supposed deficiency of longitudinal strength, this mode of construction must appear especially faulty, inasmuch as lateral adhesion instead of being, as contended, merely deficient, was altogether absent, while to those who advocated the present coil system, this variety must commend itself as affording the greatest possible amount of circumferential strength that could be realised from the material employed. Steel in the form of wire, or drawn ribbon, possessed far greater tenacity, and also greater toughness, than in any other condition, and in applying it to guns there was perfect command of the tension with which each layer was laid on. He then alluded to the labour of those who had worked in this direction, and referred to a 6-in. breechloading gun of this construction made at Elswick, and tried in the beginning of 1880. He stated that the charges used with it were large beyond precedent, and the energies developed proportionately high. Being satisfied with the results obtained with this gun, a second one of larger dimensions had been commenced, and was now finished. Its calibre was 26 centimetres, or about 10¼ in. Its length was 29 calibres, and its weight was 21 tons. In the previous gun he depended for end strength upon the thickness of barrel only; but in the new one, layers of longitudinal ribbons were interposed between the coils, in the proportion of one longitudinal layer to four circular layers. The longitudinals were secured to the runnion ring at one end and to a breech-ring at the other, and were in themselves calculated as sufficient to resist the end strain on the breech, independently of the strength afforded by the tube. The whole was encased in hoops shrunk upon the exterior of the coil, for the treble purpose of protection from injury, of preventing slipping in the event of the failure of an external strand, and of adding to the strength of the gun. This gun has already been tried, and had given results which in relation to its weight, were unexampled, except by its 6 in. predecessor. Various attempts had also been made abroad to reduce this system to practice, and it was understood that the French were at present engaged in making experimental guns upon the same general principle. With regard to the ribbon form of section, he preferred it to a square section of equal area, as being more favourable for bending over a cylinder, but any rectangular form was better than round wire, on account of the flat bedding surfaces it afforded.

He then discussed the subject of breech-loading and muzzle-loading, and the various forms of rifling. He also described the many changes that had been found necessary in the form and manufacture of powder for heavy ordnance, and the difficulties which still remained to be overcome.

As to the mounting of guns in forts and ships, he remarked that the difficulties of the problem were much greater than was commonly supposed. It was certain that machinery could be no longer dispensed with for working the guns, and that engine power must be used to economise labour and avoid exposure of the men. In the days of cast-iron smooth bores, the heaviest naval gun weighed 95 cwt., and it was deemed impracticable to exceed that limit in a ship. At the present time, the heaviest naval gun in the British service was 80 tons, and guns of 100 tons were carried in Italian ships. Instead of projectiles weighing as a maximum 94 lb., and charges of 16 lb., we had now to handle projectiles of 1,500 lb. and charges of 450 lb.; and to keep pace with foreign navies those limits of weight must be greatly exceeded. Even if it were possible to deal with guns and ammunition of such weights by manual labour, the multitude of men required for the purpose would be greater than could find standing room at the guns. Up to a certain point hand power might be so aided by machinery, as to enable larger guns to be worked by men than was formerly deemed possible; but the mechanism required to render hand power available was quite as liable to be disabled by an enemy's fire as that which would be applied in connection with engine power. There was, therefore, no reason in this respect for employing a numerous gun crew in preference to inanimate power. Automatic methods of varying out the gun, by which the gun was lifted in recoiling by slides or radius bars and recovered its position by gravitation, might in many cases be advantageously used to save labour, but in a ship the varying inclination of the deck interfered with uniformity of action. The upward motion of the gun also involved the objection of a higher port, and it added greatly to the downward shock, which became very severe on the deck where the guns were large and were fired at considerable elevation with such heavy charges as were now usual. Steam power, acting through the medium of hydraulic pressure, was already largely applied in recent ships for effecting all the operations of working the guns, and where such power was used there was nothing to gain by automatic action for returning the gun into firing position. In considering these various mechanical arrangements now applicable to naval warfare, we perceived the growth of the engineering element in our ships of war, and the importance of mechanical, as well as nautical, acquirements on the part of the officers, as also, in a less degree, on that of the men. Breechloading guns, carriages fitted with all modern appliances, shot and powder lifts, mechanical rammers and torpedo apparatus, all combined with steam or hydraulic machinery, or with both, constituted mechanisms requiring to be supervised by officers qualified as engineers, and to be handled by men trained in the use of machinery.

Before drawing to a conclusion he would advert to a subject of grave national importance. Our Navy was at present armed with guns which could not be expected to contend successfully with the best modern guns that could be used against them. Happily, most of the older ships of foreign powers were in the same predicament; but all their new vessels, and some of their older ones, were being armed with artillery which, weight for weight, was far superior in power to that of our Navy. Our service guns had simply been overtaken in that rapid progress of artillery which had been going on for the last eight or ten years; and it might be doubted whether any partial remodelling during that period would have averted the present need of re-armament; while it would certainly have involved great sacrifice and confusion of ammunition and stores. But a new departure could not longer be delayed. An irresistable demand had arisen for breechloading guns, and it was imperative to combine, with the introduction of that system, such other modifications of construction as would realize the increase of power which we now knew to be attainable.

It might, however, be asked, What better prospects of finality there was now than we had ten years ago? As to absolute finality, it would probably never be reached, but the country might take some comfort in the reflection that every stage of progress narrowed the field for further development. There was already no substantial room for improvement in the accuracy of guns; and as to power, we were nearly approaching the limit at which severity of recoil and extravagant length of gun would prohibit further advance. We might go on building larger guns almost without limit, though he doubted the policy of so doing, but mere increase of size did not revolutionize system. There seemed, therefore, to be more hope of permanency now than at any former period; but whether this were so or not, we could not, with danger, remain passive.

What, then, should our Government do in regard to the great work of re-arming the fleet? He took it for granted that all new ships would be armed with the best guns that could now be made, and that the more important of the older vessels would speedily receive the same advantage; but beyond this, so long as experience of novelties was deficient, it was a case for cautious procedure. In the mean time, no expense should be spared in judicious experiments, seeing that the expense of experiments was trifling in comparison with that of mistakes. Above all, the Government should pursue such a course as would bring into full play the abundant engineering resources of this highly mechanical country, for increasing the efficacy of our national defences.

OUR ROYAL MARINE ENGINEERS AND ENGINE ROOM ARTIFICERS.

(*Continued from page* 225.)

At the time referred to the cabin accommodation of the marine engineer was considerably increased, and a recognized officers' mess established for them as a body similar to the sub-lieutenants and midshipmen's mess. At the same time a little more freedom existed in the intercourse of the 2nd, 3rd, and 4th engineers, and the non-commissioned and lower grades of commissioned Royal Naval Officers. At this time also the sloops, corvettes, frigates, two deckers and three deckers, the wooden walls of old England received their death blow, and with their lofty spars and clouds of canvas quickly disappeared. In their place came the *Warrior*, *Black Prince*, *Defence*, and numerous other iron armour clads with heavy and massive hulls and comparatively limited areas of canvas. From that time till the present the duties and uses of the sailor and sailor officer of former days has decreased considerably, and in the same ratio those of the royal marine Engineer and stoker have increased. The simple propelling paddle, or single screw-engine of a comparatively auxiliary nature, referred to as the first introduction of steam power in our Navy, is now replaced by massive and complicated twin screw, surface condensing, high and low pressure engines, as well as powerful single screw, and in some cases paddle engines.

The construction and nature of these engines require the care and attention of the most highly skilled marine engineers to such an extent, that the more practical details requiring manual skilled labour which could be carried out by engineers less highly trained, has led to the appointment of a class of working engineers termed engine room artificers. Not only has the marine engine of our man-of-war developed into a large complication of massive machinery of highly skilled design, but the stupendous complications of engineering skill embodied in our modern man-of-war calls for the appliance of machinery to work nearly every portion of the structure. This is carried out either by gearing from the main engine or from auxiliary engines fitted up in different parts of the vessel. Turrets, guns, capstans, pumps &c., are worked by machinery, the anchor is hove up by machinery, and in the case of vessels being rigged the severest strains brought on tl
set up by machinery. The cutters, pinnaces and to
carried by our men-of-war are propelled by means of s
engines of delicate structure requiring the greatest skil
tion. The progress of marine engineering science ha
itself to such an extent that at the present day very lit
paid to the rig of our man-of-war, in fact many of our n
armour clads are mastless, thus showing that sails as
agent even in the most auxiliary degree may be dis
altogether. This has further reduced the number and
blue jacket and the sailor officer, and respectively in
value of the royal marine engineer, naval artificer, and s
royal marine engineer apprentice of the past is now
the engineer student in our royal dockyards. The yo
to follow this profession only obtains his appointment
or gentleman apprentice by successfully passing a high
petitive examination. In order to be fully fitted for th
youth intending to become a candidate has to be spec
from the commencement of his education, which mu
highest order, and necessarily of an expensive nature. A
his appointment as an engineer student it is only by
application and study that he can hope to rise in his pi
pass higher class examinations in practical and theore
engineering when he is allowed to finish his studies
man-of-war, wearing a uniform and holding a positio
similar to that of a cadet graduating for the post of a c
officer of the Royal Navy.

The expense attending the education of a youth p
his maiden examination, combined with the extra exp
cation and uniform whilst graduating as an engineer
only be borne by parents in a good position in life wh
of education reached by the royal engineer before he
a full appointment in the Royal Navy entitles him t
gentleman. Considering that commissioned navigatin
charge of the seamen and navigating arrangements of
war can only receive a good education and graduate
way, it is not a matter of surprise that the engineers
hard to fit themselves to take charge of the complicate
the different parts of a ship, and to direct the num
room artificers and stokers who are so quickly sup
seamen in many of the requirements of a man-of-war,
to be recognized as officers and gentlemen of positi
reviewed generally the introduction of the royal mar
into our navy, the gradual development and value of t
auxiliary engines employed in our ships, togeth
increased knowledge and higher class duties required of
it would appear that his position as regards remu
status should be on an equal footing according to t
bestowed on the other offices of the ship. At a fu
will show how far this is now carried out. It is evid
position of the royal marine engineer has improved ve
it is a question if more still remains to be done. We
paring the increase of pay gradually brought about by
nized position from the time of the introduction of th
our navy with that of commissioned officers, endeavour
exact position in which our royal engineers now sta
facts which would be convincing as to whether the am
sideration they merit is meted out to them, or whether,
hand, their case at present is such an aggrieved one,
general expression of feeling now in existence they a
believed to occupy.

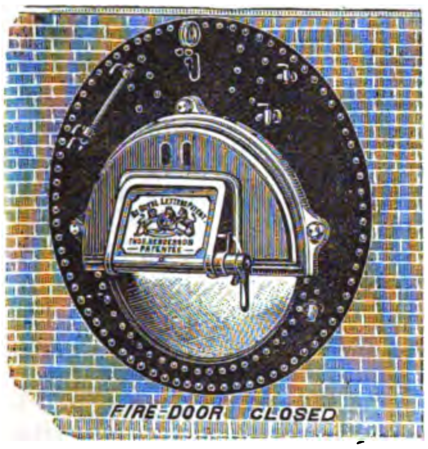
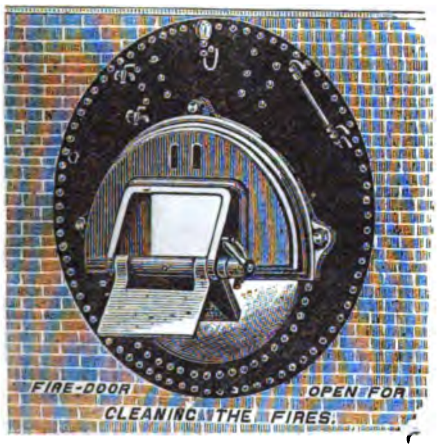
HENDERSON'S PATENT FIRE-DOOR.

IN connection with the Smoke Abatement Exhibition, now being held at South Kensington Museum, considerable interest has been caused through the energetic and business-like efforts of the committee in drawing together many useful and ingenious appliances, with the object of facilitating the prevention of smoke, and the saving and utilizing to the utmost extent, coal and its products during combustion. It is also satisfactory to find that the public as well as the exhibitors appreciate these efforts by attending in such force.



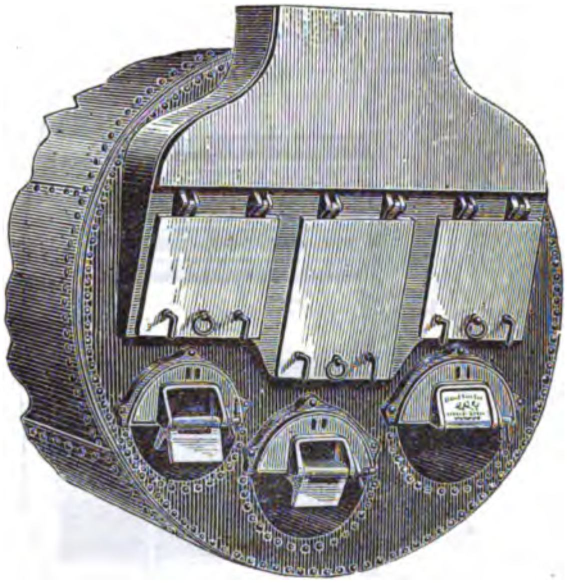


FIRE-DOOR OPEN FOR CLEANING THE FIRES.

Amongst the many exhibits, we here give a description with explanatory illustrations of a simple and ingenious arrangement of fire-door, which has been gradually gaining in favour for these last few years. That of Henderson's Patent Fire-door, invented and patented by Mr. Thos. Henderson, of Liverpool, whose name has long been coupled with the manufacture, &c., of mechanical stokers and matters pertaining to the combustion of fuel generally.

The fire-door itself is of a ∠ shaped form, with the hinge at the point of the angle, and, unlike other doors, is placed at the bottom, in line with the dead plate or underneath the fire-door opening, and not at the side as is usually done.

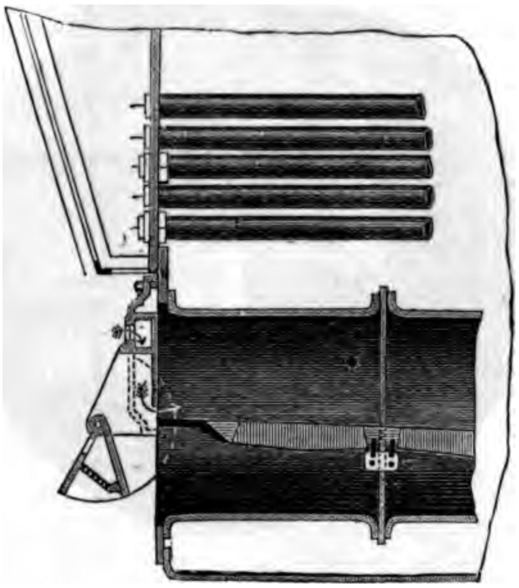
This angle-plate or door swings between two side cheeks or projections from the casting forming the furnace front. When the door is closed, the lower leaf of the angle-plate is in line with, and forms part of the dead plate. When the door is pushed inwards, so as to open the door for firing &c., the top or upper leaf falls into the position previously occupied by the lower leaf, in line with the dead plate, while the lower leaf falls down below to a corresponding angle to serve the double purpose of protecting the stoker's legs from the heat of the furnace, and to partly regulate the air, and also heat it previous to its admission under the bars.



When it is desirous to clean the fires or withdraw clinker, the angled door is simply pushed further in, in an inward direction until both leaves hang downward like the letter A. The clinker can then be withdrawn with the greatest facility, through the opening thus left between the door and the dead plate, without being scattered over the plates of the stokehole, while the position of the hanging door protects the fireman from the fierce heat of the withdrawn clinker, while from its formation it protects him also from the sulphur and suffocating fumes so deleterious to men in close stokeholes, especially in tropical latitudes, by directing the gaseous matters up through the opening formed by the vacant plate, and thus keeping the stokehole ventilated. The door is nicely balanced so that it can be easily moved into any required position by a handle at the side for the purpose

This simple fact of its being so easily opened and closed surprisingly illustrates to the observer how greatly it facilitates and eases the work of the generally overwrought stoker. An air chamber is cast in the furnace front for the double purpose of keeping the front cool, and for heating the air passing through it to the furnace. The back plate of furnace front, as also a plate cast on, and at right angles to the lower leaf of the angled door, is perforated for the admission of air, which can be regulated as required for the prevention of smoke by a slight movement of the door itself.

The illustrations show the Patent Fire-Door as fitted to an ordinary Cornish boiler, one view showing the door when closed, and the other when in the position for cleaning the fires, and also as fitted to a three flued marine boiler; the three furnaces showing respectively the positions when closed, when firing, and when full open for cleaning. The two views illustrating longitudinal sections of the furnace represent the door when in position for firing, and when in position for cleaning, and the direction of the air currents.



These fire-doors have been, and are being, fitted to several vessels in the Atlantic and East India trade, including the "Allan" Line, the "City" Line, the "Wilson" Line, and the "Temperly" Line, &c., of steamers, as also at Messrs. Clark's Thread Mills, Glasgow, Messrs. Leitch's Sugar Refinery, Liverpool, Messrs. Goodman Brothers' Works, Bermondsey, and many others.

We herewith append an experimental test for smoke, taken in London during December last, with a Cornish boiler fitted with the above apparatus.

Test of boiler fitted with Henderson's **Patent** door and front, December 23rd, 1881.
Coal weighed 5 cwt. or 560 lbs.

Another test was recently made at the Sugar Refinery of Messrs. James Leitch & Co., by Mr. Donaldson, Consulting Engineer, of Liverpool. The range of boilers consists of eight double-faced Lancashire boilers, two of which are usually out of use for cleaning and repair, the six boilers in constant use consume on an average 35 tons of coal per 24 hours, which means continuous and hard firing; the test took place at 6 p.m. at the change of the day and night shift of men, the fires being cleaned twice during each watch, at the beginning and intermediate between the watches.

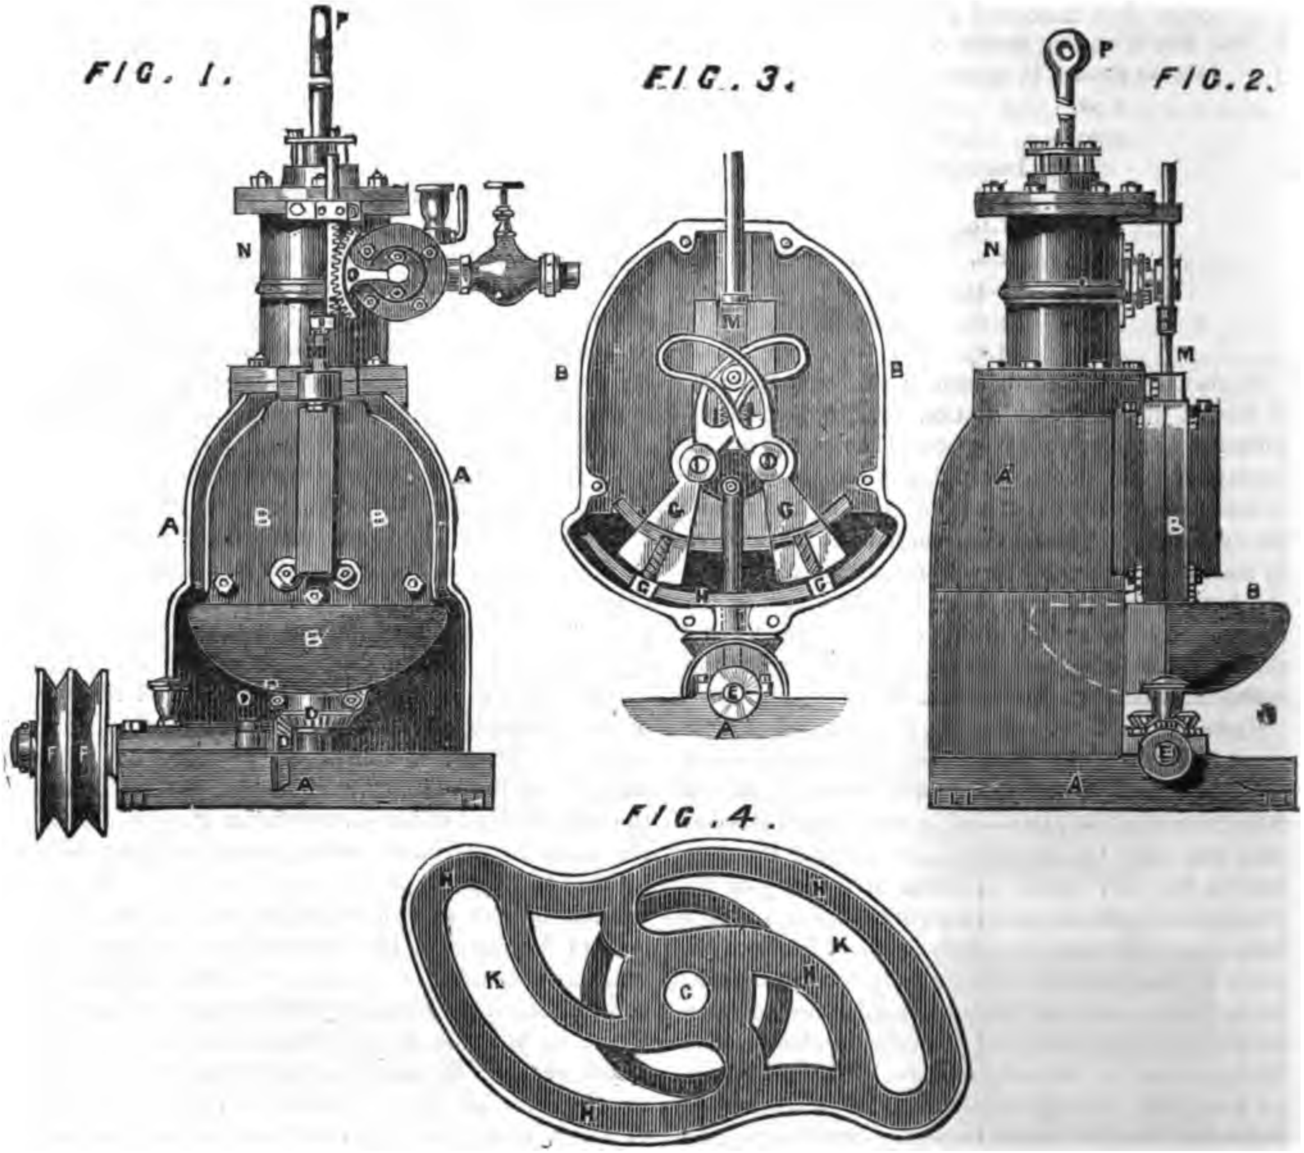
Upon the fresh men starting, six of the fires were cleaned and fired with fresh green coal as rapidly as it could be done. Upon the introduction of fresh fuel entirely covering the grate—and in one instance this was done with both the furnaces of one boiler at the same time—a dull grey smoke appeared at the top of the chimney, as it were shot up by a slight explosion, and then immediately died away, generally in about five seconds, and in no case after repeated trials more than ten seconds; during these intervals of firing the smoke was only perceptible as a slight haze, and generally the chimney had the appearance of not being at work. All these boilers are fitted with Henderson's Patent Fire-Doors, and we understand that the Smoke Inspectors have long ceased to trouble the proprietors of these works.

Altogether this simple arrangement of fire-door and furnace front, invented by Mr. Henderson is well worth the attention of those interested in the vexed question of Smoke Prevention, full sized models of which may be seen at South Kensington, as also, we understand, at the forthcoming Naval Exhibition, at the Agricultural Hall.

THE PATENT LIGHTNING-SPEED CHECK GOVERNOR.

AFTER the numerous steam governors that have been invented during the last ten years and the researches of so many eminent men into this department of engineering, we might naturally suppose that no further material improvement would be arrived at; however, we must admit that the one which we now present to our readers is, in every respect, worthy of our careful consideration. This governor, which was patented some time since by Messrs. Gibson & Nicholson, Engineers, Sunderland, seems on first sight to be complicated, but on a little closer examination its working, and the reasons for the use of its several parts will be more apparent. In reference to the illustrations, Fig. 1 represents the front elevation; Fig. 2, side elevation; *A* is a metal cover half enclosing the revolving case *B*, which is loose on the shaft *C* (is shown in Fig 3), which derives its motion from the pinions *D*, shaft *E* and driving pulleys *F;* Fig 3 shows the inside of the case enclosing the weights *G* (which move on the centres *I*), and the disc *H*, which is more clearly shown in the enlarged plan Fig. 4. The pins *G* project below the end of the governor balls (so called), and are made approximately to fit the slots *K*, in the disc with rollers on them to reduce friction. The springs *L* serve to prevent a too great movement from the action of the slots. The apparatus being thus arranged, it will be seen that by the action of centrifugal force on the rapid rotation of the governor case, the weights will tend to draw in the rod *M*, and to actuate the valve-rod *O*. The addition of the cylinder quickens the motion of the throttle valve-rod which is attached at *P*, by admitting the steam to the under or upper side of the piston in the cylinder *N*, as the case may be. As the rotation of the case increases in rapidity the arms tend to diverge, and like an ordinary governor, the weights will tend to diverge or come together in accordance with the greater or less speed of revolution. There is, however, by the arrangement of apparatus which we have described, a *second action set up*, due to the curve of the slot shown in Fig. 4, the effect of which is to assist the movement of the governor weights during any change of speed; thus, should the speed be suddenly accelerated, the curve of the slot is so proportioned, that the pin *G* will not attain the full amount of acceleration, if it should take a position more distant from its centre of revolution than it had before, and as the pin *G*, when not at its extreme stroke, is free to take this more distant position, it will naturally by its own inertia and the inertia of the balls tend to do so, and by this effort tend to disturb the previously existing equilibrium of the governor weight due to centrifugal force, giving the governor a very quick action. On the other hand, should the speed of revolution be suddenly diminished, as the pin *G* can take a more advanced position in the line of its revolution by an approach to its centre of revolution, the force of impetus will cause an effort to

FIG. 1. FIG. 3. FIG. 2. FIG. 4.

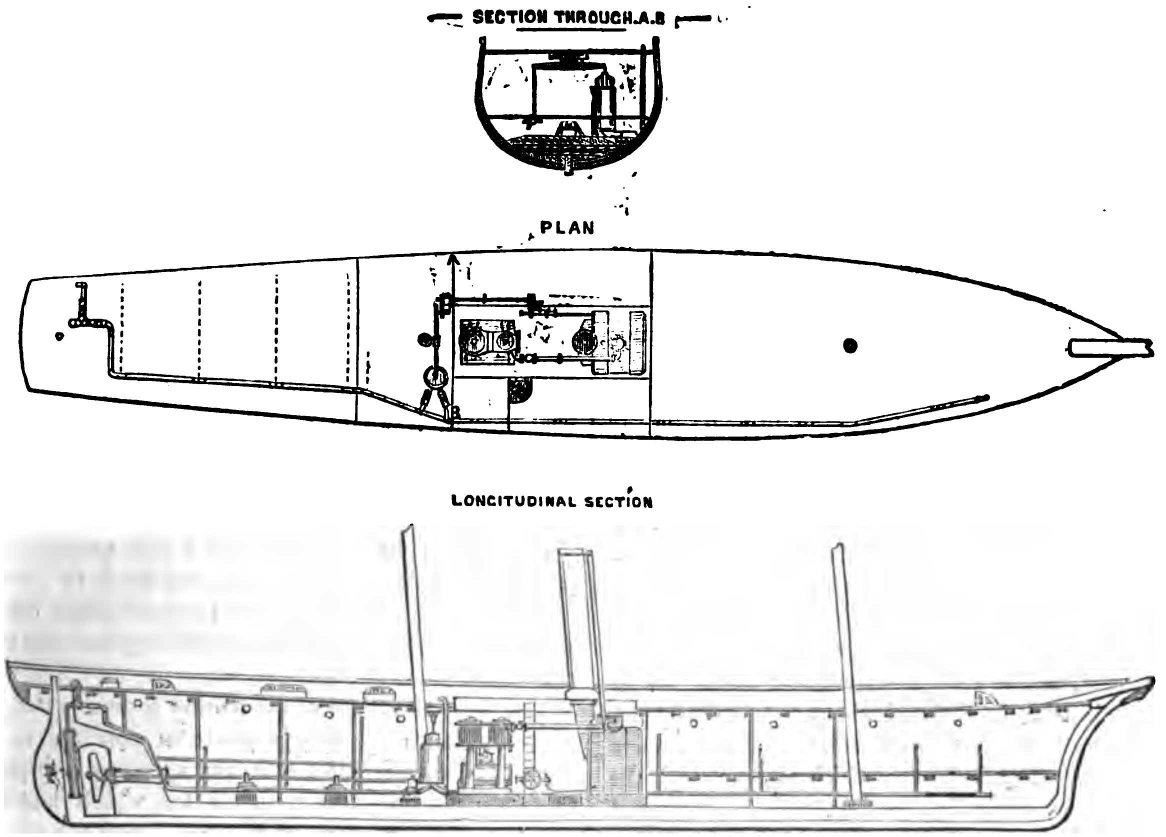


THE PATENT LIGHTNING-SPEED CHECK GOVERNOR.

attain this advanced place, and thus again disturb the equilibrium of the governor weights in the opposite direction. In order to give full effect to this action, the driving of the governor weights are caused to be transmitted through the pins *J*, instead of through the centre spindle. What is claimed by the inventors of this governor is not so much the mechanism just described, but the real invention is the combination of mechanism, consisting of curved slots and sliding pins, actuated by inertia and momentum and controlling springs, so as by these actions jointly to produce a governing movement for steam engines.

Some of the advantages claimed by the inventors of this governor are—simplicity of construction, and consequently, not easily deranged; easily adjusted when required for various speeds; sensitive action, as its name implies; being actuated direct from the engine and independent of springs.

The working parts being entirely encased are kept perfectly free from dust and dirt, and can all be oiled while in motion.



The Board of Trade S.S. "Ceylon" fitted with the NORTON AUTOMATIC AND POWER VENTILATORS, Manufactured by A. G. Mumford, of Colchester.

This Drawing is reduced to 1-4th the size of a Scale Drawing of 3-16ths inch to the foot.

THE NORTON POWER HOUSE AND SHIP VENTILATOR.

THE ventilation of ships is a subject which has been studied and experimented on by various authorities for many years past. Numerous methods for the purpose of introducing currents of fresh air to different portions of a vessel have been tried in the shape of patent cowls, shafts, and air-trunks, and where these have failed, the fan-blower has been used, driven either by air or steam to introduce currents of fresh air into double bottoms, stokeholds, and other confined portions of our modern ship. By the above methods, the sanitary condition of the most confined portions of vessels has been considerably enhanced. It has, however, been felt that something still further was required to complete our marine ventilation, as also the ventilation of extensive public buildings, mines, tunnels, &c.

By the application of the ventilating arrangement termed the Norton Ventilator, the root of the sanitary evil is reached and removed in the shape of the foul accumulations which are automatically pumped away from the various compartments, leaving a space into which fresh air will readily rush. As is usually the case, this plan seems so simple, that it is a wonder it was not thought of before. The introduction of a shaft to a compartment or a series of compartments of a vessel which are charged with more or less noxious atmosphere, does not necessarily cause the expulsion of the evil, and the introduction of fresh air; in fact, in many instances, the bulk of the bad atmosphere having no channel of egress simply stagnated the action of the fresh air in the shaft. The same remarks refer to mines, tunnels, &c. By the use of the Norton Automatic and Power Ventilators, it will be readily seen how effectively the foul air question is dealt with, and that evil entirely removed.

Figs. 1, 2 and 3 show the general arrangement of the Norton Automatic and Power Ventilators, as fitted to the Board of Trade s.s. *Ceylon*, and manufactured by A. G. Mumford, of Colchester.

The apparatus consists of a power ventilator for use in steamers, buildings, tunnels, or any enclosed place where power can be applied, while in the case of ordinary vessels, it is so constructed as to work automatically by the mere movement through the water. By order of the Board of Trade, both systems have been combined on board the *Ceylon*, with a trifling additional cost. A circular iron tank 33 in. in diameter, 4 ft. in height, and two-thirds full of water is provided, and inside this is an air-chamber or cylinder 12 in. less in diameter than the tank, with an oval top and open at the bottom. The air-chamber or bell, as it is called, is made to plunge up and down inside the tank, by the application of steam or other motive power, the water forming the packing of the pump. Connected with the bottom of the tank are two valves, one used as an exhaust and the other as a discharge valve. The first-named valve is in connection with a line of 4-inch piping which runs the entire length of the vessel, and from this there are branch pipes of 2 in., 1½ in. and 1 in. diameter leading to the coal-bunkers, bilges, state-rooms, cabins, lockers, and under the ceiling of the ship. By the operation of the air-chamber, the air is constantly exhausted from every part in which a branch pipe is fixed, and to such an extent that all the air in the vessel is entirely changed about once every hour. The importance of the result thus attained will at once be apparent. The foul gases which accumulate in the bunkers, bilges, and other enclosed spaces are carried clear away and discharged into the open air, where they become innocuous, while in the case of the cabins and all spaces between decks the atmosphere is kept perfectly pure and inodorous. The automatic ventilator is operated by the movement of the ship, and can be used at sea when the power ventilator is not required to be used. It consists of a copper pipe or piston attached to the stern post, and is 9 feet long, 15 inches in diameter fore and aft, and 5 inches in diameter crosswise, and is made to conform to the shape of the post. From this a 4-inch pipe passes into the stern of the ship, where it is attached to a pair of valves similar to those connected with the power ventilator. As the stern of the vessel rises in the sea, the water in the pipe or cylinder falls, thus creating a vacuum, to fill which the air is drawn through the same system of pipes already described. The downward movement of the stern towards the sea causes the water to rise in the cylinder, and the air which had been previously drawn in from the various parts of the vessel is forced through the discharge valve into the open air outside. It has been found from actual tests, that with a rise and fall of the ship of only one foot, the automatic ventilator exhausts no less than 5,000 cubic feet of air per hour, while the power ventilator, worked from a beam attached to the donkey engine, is capable of exhausting 38,000 cubic feet per hour.

At the trial everything connected with the apparatus was found to work most efficiently, and to more than justify the claims made for it by the inventor.

The Criterion Theatre having tried other methods of ventilation without satisfactory results, is most successfully ventilated since the adoption of this plan, as are also many large buildings and offices. Applied to ships, it will improve the sanitary condition of every sea-going vessel; and for merchant vessels carrying cattle, grain, fruit, tea, coal, or sugar, it is invaluable, as with this ventilator attached there will be no danger of cattle suffocating for want of pure air, of grain heating, tea sweating, fruit rotting, coal igniting spontaneously, or of sugar dissolving by reason of damp holds. Applied to coal vessels, it would remove all danger of explosion from coal gas, and at the same time by contributing to the purity of the atmosphere, have a very beneficial effect upon the wood and iron-work.

Properly applied to coal mines it will provide every part of the mine with pure air, and tend to prevent explosions. Tunnels, also, by its application can be kept free from smoke, and constantly supplied with fresh air.

The great advantage of the Norton system is that the apparatus in size is always made to conform to the amount of work required of it, and adjusting it to public buildings and ships, the purposes for which buildings and ships are used, and the number of persons occupying them especially considered, and the apparatus constructed and applied accordingly. The plan of the inventor is in every case to provide a certain quantity of fresh air per minute for each person occupying the premises. Hence it must be apparent that the ventilation must be positive and effective.

Of the many inventions brought forward for years past on boat-lowering apparatus and saving life at sea, few have received any lasting attention, principally on account of the fact that the mechanism was of an exceedingly complicated character, and the practical application of different inventions gave generally unsatisfactory results. Occasionally inventors have supplied a tolerably simple invention which they have had adopted by different owners, Governments, &c. We have had brought to our notice the boat-lowering and disengaging gear of "the British and Foreign Boat-Lowering Apparatus Company, Limited," of 4, Great Winchester-street Buildings, E.C. This invention from the use of a ball in the place of hooks, which are most objectionable and dangerous, combined with the facility for lowering and attaching boats under every condition, appears to be the best of the many numerous methods in existence. The Company are making rapid progress with their lowering gear, and also with their davits, having fitted a considerable number of vessels, and received the most unqualified expressions of satisfaction from all who have used them. The Peninsular and Oriental Company's s.s. *Rosetta*, and Messrs. Siemens Brothers Telegraph ship *Farady*, are amongst the latest vessels fitted with this gearing. Admiral Sir John E. Commerell, R.N., K C.B., V.C., reports very favourably on this boat-lowering apparatus, and it is highly probable that, as this is more generally adopted, it will command universal satisfaction,

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of* THE MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Goldcliffe.—On December 28th the Palmer Shipbuilding and Iron Company, Limited, launched from their Howden yard the iron screw-steamer *Goldcliffe*, built to the order of Messrs. D. H. Morgan & Co., Newport. She measures 250 ft. in length, by 33 ft. beam and 16½ ft. depth of hold; her dead-weight carrying capacity represents 1,850 tons. Her engines are Palmer's construction of 120-horse power nominal, the cylinders being 28 in. and 54 in. in diameter respectively, with 36 in. length of piston stroke. She is fitted with Emerson Walker & Co.'s patent windlass. The Palmer Company put into the water last year a total tonnage of over 50,000 tons.

General Roberts.—On December 28th the Palmer Shipbuilding and Iron Company, Limited, launched from their Jarrow yard the screw-steamer *General Roberts*, built to the order of Barnes, Cuthrie & Co., Cardiff. She measures 258 ft. in length, by 35 ft. beam, and 18 ft. depth of hold, and has a carrying capacity of 2,000 tons dead-weight. She is fitted with patent windlass by Emerson Walker & Co. Her engines, also constructed by the Palmer Company, are of 130-horse power nominal, the cylinders being 31 in. and 51 in. in diameter respectively, and 36 in. length of piston stroke.

Afrikaan.—On December 28th there was launched from the yard of Messrs. Raylton Dixon & Co., Middlesbrough, a steamer which was named the *Afrikaan*, for the New Afrikaan Company of Rotterdam. She is 232 ft. over all, 31 ft. 3 in. beam, 22 ft. depth of hold, and will carry 2,550 tons, having a gross tonnage of about 1,227 tons. She is built on the spar-decked rule, and has iron main deck, steam-steering gear, and accommodation for captain and first-class passengers aft. Her engines, of 100-horse power, will be supplied by Messrs. Blair & Co., of Stockton. She is intended to be employed in the trade between Rotterdam and the Congo River. On leaving the ways she was named the *Afrikaan* by Mr. Step, the inspector for her owners. This was the thirteenth vessel built last year by Messrs. R. Dixon & Co., and makes up their tonnage launched to 25,036 tons, or about one-third more than has ever been launched from this yard in one year before.

Cumbria.—On December 31st a screw steam yacht, named the *Cumbria*, was launched from the yard of Messrs. C. Mitchell & Co., on the Tyne. The yacht was built for the Earl of Lonsdale, and being intended for long cruises she will be fully rigged as a barque. She is of 615 tons, and will be fitted with engines of 100-horse power.

Inchboroa.—On December 31st there was launched by Messrs. C. Mitchell & Co. the screw steamer, *Inchboroa*, of 3,000 tons burthen, which has been built to the order of Messrs. Harrison, Fraser & Co., of Liverpool. The vessel was christened as she left the ways by Mrs. H. B. Harrison.

John Readhead.—On January 15th the first launch of the year from the yard of Messrs. John Readhead & Co., West Docks, South Shields, took place. The vessel was named the *John Readhead*. She is of the following dimensions:—Length, 255½ ft.; breadth, 34½ ft.; depth, 19 ft. 8 in. She will have a long raised quarter deck, and a bridge amidships. She will be fitted with engines constructed by Messrs. Readhead, of 155 nominal horse-power, and all the latest improvements; she will be classed 100 A 1 at Lloyd's; her deadweight carrying capacity will be 2,300 tons. She has been built to the order of Messrs. Franz Rahtkens, Olsen & Co., of Middlesbrough, and is intended for the Mediterranean trade. The ceremony of christening the ship was performed by Miss Olsen.

Bengeo.—On January 19th the Whitehaven Shipbuilding Company launched a steamer of about 1,700 tons, built to the order of Mr. Joseph Hoult, Liverpool. On leaving the ways she was christened *Bengeo* by Mrs. Handley, wife of James Handley, Esq., of Runcorn. The builders have three similar steamers in course of construction for the same owners.

Nymphæa.—On January 19th there was launched from the yard of the Tyne Iron Shipbuilding Company (Limited), of Willington Quay, on Tyne, an iron screw steamer of the following dimensions, viz.:—Length between perpendiculars, 287 ft.; breadth, 37 ft.; and depth, 23 ft. 6 in. The vessel has been built to the order of Messrs. Joseph Robinson & Co., of North Shields, and is named the *Nymphæa*. Her engines are supplied by the North-Eastern Marine Engineering Company (Limited), of Sunderland, and are as follows:—Diameter of cylinders, 33 in. and 63 in.; length of stroke, 39 in. She is fitted with all modern appliances, including Tyzack's patent anchor.

Mastiff.—On January 19th Messrs. R. Thompson & Sons launched from their shipbuilding yard at Southwick, Sunderland, an iron screw steamer, built to the order of Messrs. R. Thomson & Co., 72, Mark-lane, London, of the following dimensions, viz.:—Length over all, 251 ft.; breadth, 35 ft.; depth of hold, 22 ft. 9 in.; having been constructed under Lloyd's special survey to class 100 A 1 for the spar-deck rule, and also under the personal superintendence of Mr. M'Hall. There is accommodation aft for captain and spare berths; the officers and engineers are amidships, and seamen and fireman forward. She has large chart-house, pilot-bridge, look-out bridge forward, and smoke-house aft, with water ballast in both holds, and is fitted with three steam winches and donkey boiler, Harfield & Co.'s patent windlass, steering gear amidships, patent screw gear aft, anchor crane, and all the latest improvements, and will have engines of 130-horse power by Messrs. H. H. Morton & Co., of Leith. On leaving the ways she was named the *Mastiff* (pro. tem.) by Mrs. R. A. Wood, of Newcastle.

Grassendale.—On January 19th an iron built sailing ship, named the *Grassendale*, was launched from the yard of Messrs. Williamson & Son, of Workington and Harrington. The ship was the first one that was launched from the Workington yard, but the forty-seventh from the yard of the same firm as far as Harrington is concerned. She is built principally for the Australian and Californian trades, and is owned by a Limited Liability Company, of which Messrs. R. W. Leyland & Company, of Liverpool, are the managing owners. From the following particulars one may judge of her capacity:—Her total length, over all, is 280 ft.; her breadth, 39 ft.; her depth of hold is 23 ft. 7 in.; and her draught, when loaded, is 21 ft. 6 in.; her gross tonnage is 1,850 tons, but she is built to carry 2,900 tons. She is classed 100 A1 at Lloyd's, the highest class; and will be in command of Captain Richardson. The first frame was erected in March, 1881, so that she has not been altogether twelve months in course of construction.

Benhope.—On January 20th Messrs. Caird & Purdie, of Barrow-in-Furness, launched a steamer of 2,000 tons for Mr. Joseph Hoult, of Liverpool, and have orders for two similar steamers for them. Miss Finlay, daughter of Edmund Finlay, Esq., of Liverpool, performed the ceremony of naming the steamer *Benhope*. These steamers will be fitted with steam steering gear and all latest improvements, and will form a valuable addition to the owner's fleet.

Frankistan.—On January 21st Messrs. Oswald, Mordaunt & Co., launched from their shipbuilding and engineering works, Southampton, an iron sailing ship, of 2,000 tons register, named the *Frankistan*, built for the British and Eastern Shipping Company, Liverpool, of the following dimensions:—Length, 270 ft.; breadth, 29 ft. 6 in.; depth of hold, 24 ft. The ship is built with full poop, monkey forecastle, and large midship house for crew. She is fitted with Harfield's patent windlass for lifting anchors, and all latest improvements, including an excellent arrangement for ventilating cargo, &c. She is intended to class 100 A 1 at Lloyd's and 20 years in the Liverpool Underwriters' Registry. The ceremony of naming the vessel was performed by Miss M'Donald, daughter of the managing owner. When the vessel is fitted out, she will be under the command of Captain Brown, who has been superintending her while building.

Matthew Bedlington.—On January 21st an iron screw steamer was launched from the Whitehall Shipbuilding-yard, Whitby, and will form an addition to Messrs. T. Turnbull & Co.'s fleet. The new steamer is 280 ft. long, 38 ft. in breadth, and 20 ft. 9 in. depth, and has a deadweight capacity of about 3,050 tons. He engines, by G. Blair & Co., of Stockton, are 180-horse power. She is classed 100A 1 at Lloyd's, and is fitted with every modern appliance and improvement. The steamer, on leaving the ways, was christened the *Matthew Bedlington* by Mrs. M. Bedlington, of Robin Hood's Bay. She will run chiefly in the Indian and American trades.

Hawarden.—On January 24th Messrs. W. Gray & Co., West Hartlepool, launched from their yard an iron screw steamer of the following dimensions:—Length, 268 ft.; breadth, 35 ft. 6 in.; depth, 19 ft. 9 in.; to class 100 A 1 at Lloyd's; to the order of Mr. T. S. Hudson, of West Hartlepool; intended for the American or Indian trade; to carry 2,500 tons. She is fitted with all recent improvements, including steam steering gear amidship, and tiller gear aft, patent windlass by Emerson & Walker, and four steam winches. The engines are fitted by Messrs. Thomas Richardson & Son, of Hartlepool, 180-horse power. On leaving the ways the christening ceremony was performed by Miss Farmer, of Seaton Carew, the vessel being named the *Hawarden*. This is the fifth vessel built by this firm for Mr. Hudson, and another is in progress.

LAUNCHES.—Scotch.

Mahinapua.—On December 31st Messrs. William Denny Brothers launched from the Leven Shipyard, Dumbarton, a steel twin-screw steamer of about 426 tons gross register for the Union Steamship Company of New Zealand, which on leaving the ways was named *Mahinapua* by Miss Janet Denny, of Helenslee, daughter of Mr. Peter Denny, senior partner of the firm. The dimensions of the vessels are:—Length between perpendiculars, 160 ft.; breadth (moulded), 26 ft. 10 in.; depth (moulded), 13 ft. 4 in. The vessel will be fitted by Messrs. Denny & Co., Dumbarton, with two pairs of compound surface-condensing engines, having cylinders 17 in. and 30 in. diameter and 24 in. stroke. The *Mahinapua* is intended for the New Zealand coasting trade, the exigencies of which had led to her construction on the twin-screw principle. She is built to the highest class at Lloyd's, and her construction has been personally superintended by J. Darling, superintendent, Union Steamship Company of New Zealand. She will be taken out and commanded by Captain Jones, of the same company.

Inversnaid.—On January 4th Messrs. Robert Steele & Co., Greenock, launched a sailing ship whose dimensions are:—Length, 240 ft.; breadth, 38 ft.; depth, 22 ft. 7 in.; tonnage, 1,559. She has been built for Mr. John M'Gregor, lately of the firm of Messrs. J. & W. Stewart, and is intended for the East India trade. As she left the ways she was named *Inversnaid.*

Wicklow.—On January 7th there was launched from the shipbuilding-yard of Messrs. Robert Steel & Co., Greenock, an iron screw steamer for the coasting trade of the Clyde Shipping Company. This vessel has been built under special survey, to class 100 A 1 in Lloyd's Register, has been constructed with a double bottom fore and aft, on the bracket system, and registers 1,020 tons gross. The following are her principal dimensions:—Length, 225 ft.; breadth of beam on spar deck, 28 ft. 9 in; on main deck, 30 ft.; between deck, 30 ft. 10 in.; and will be propelled by a pair of surface-condensing engines of 180-horse power. These engines will have two cylinders of 27 and 57-in. diameter, by 48-in. stroke, having a starting cylinder with Routledge valves, and donkey engine for working same. In addition she will have steam winches, cranes, Emerson, Walker & Co.'s patent windlass, and all other modern appliances for loading and discharging cargo with ease and despatch. The boilers, two in number, are constructed to Board of Trade requirements for a working pressure of 100 lbs. per square inch, and all the component parts of the engines have been made of strength sufficient to stand that pressure. The vessel on leaving the ways was named *Wicklow* by Miss May Brymner, daughter of Bailie Brymner, one of the partners of the firm, being thereafter towed into the Victoria Harbour, where her engines, which have been made by the builders, will be fitted in.

James A. Garfield.—On January 9th Messrs. William Hamilton & Co. launched from their shipbuilding-yard at Port Glasgow an iron screw steamer of the following dimensions, viz.:—Length, 300 ft.; breadth, 36 ft.; depth, 25 ft. 6 in. To carry upwards of 3,000 tons deadweight; horse power nominal, 250. This steamer is the first of a new line, to be called the "President Line," and has been built to the highest class at Lloyd's. She is fitted with M'Lachlan & Co.'s patent steam steering gear, steam windlass, and steam winches, as well as all the latest modern improvements for facility and economy in loading and discharging, and has accommodation for 30 first-class passengers. Her 'tween decks are specially adapted and ventilated for carrying troops, cattle, fruit, &c. She is to be commanded by Captain James O'Neill (late of the ship *G. W. Wolff*), under whose superintendence the steamer has been built. On leaving the ways the steamer was named *James A. Garfield*, by Miss Jeanie Hamilton. The vessel has been built to the order of Messrs. D. W. R. Read & Co., London, New York, Philadelphia, and Baltimore, who are the managing owners of the new line.

Bandeath.—On January 16th Messrs. Russell & Co. launched from their Port Glasgow yard a barque of the following dimensions:—Length, 180 ft.; breadth of beam, 30 ft. 6 in.; depth of hold, 18 ft. This vessel has been built for Messrs. W. and J. Lockett, Liverpool, and is the first of two vessels for this firm. She is of similar dimensions to the *Ben Lawers*, built by Messrs. Russell & Co. for Messrs. Gourlay Bros., Glasgow, several years ago. As she left the ways she was named the *Bandeath* by Miss Russell.

Garvel.—On January 18th Messrs. Blackwood & Gordon launched a new lightship for Garvel Point. The ship is 40 ft. in length, on the deck of which is a large erection, fitted up with what is called the eclipse light. There is on board a large gas tank, which will be periodically filled by the steamer *Torch* from the gasworks of the Lighthouses Trustees at Port Glasgow. The new ship has been named the *Garvel.*

Cloncaird.—On January 19th Messrs. John Reid & Co., Port Glasgow, launched a steel barque called the *Cloncaird*, for Messrs. John Kerr & Co., Greenock. The new vessel is 1,300 tons register, and 1,500 tons builders' measurement. This is the fifth vessel built by Messrs. Reid & Co. for the same firm. The *Cloncaird* will be commanded by Captain Murdoch, who has been for a long time in the employ of Messrs. Kerr & Co.

Kansas.—On January 19th Messrs. Chas. Connell & Co. launched from their ship-building yard on the Clyde, the *Kansas*, an iron full-powered screw steamer, built to the highest class both in English and French Lloyd's, and to the Board of Trade requirements, for Messrs. George Warren & Co., Liverpool. She has been built to the plans and under the superintendence of Mr. Gilbert S. Goodwin, the Company's consulting engineer, and with special reference to their service between Liverpool and Boston. Her principal dimensions are:—Length between perpendiculars, 435 ft.; breadth, 43 ft. 6 in.; depth, 35 ft.; gross tonnage, 5,300 tons. The engines, which are on the compound principle, will indicate 3,000-horse power, and will be supplied with steam from four steel boilers at a working pressure of 80 lbs. to the square inch. The steamer is fitted with four decks, three of which are iron throughout the entire length, and sheathed with wood planking. She is divided into eight water-tight compartments, and her deadweight cargo and coal capacity will be 5,700 tons. The steering and engine telegraphs are by Messrs. Chadburn & Son, Liverpool. She will also be supplied with Sir William Thomson's steering compass, and his latest improved sounding machine. The new vessel is four-masted, square rigged, with double topsail yards on the fore and main masts. All the masts are fitted with cargo derricks, spans, &c., at each hatch, and with every requirement for rapid and safe working of cargo. The *Kansas* will be commanded by Captain A. H. Burrell, the senior commander of the Warren Line. The ceremony of naming her was performed by Miss Edith Warren, daughter of the late Mr. George Warren, Liverpool.

Congo.—On January 20th Messrs. Cunliffe & Dunlop launched from Inch Works, at Port Glasgow, the screw steamship *Congo*, which they are completing as an addition to the fleet of the British and African Steam Navigation Company. The new steamer, which is entirely built of steel, is 300 ft. long by 36 ft. beam and 22 ft. depth moulded. She is classed in the highest grade of Liverpool Lloyd's, with Board of Trade passenger certificate, and is intended specially for trading between Liverpool and the West Coast of Africa. The whole of the accommodation for passengers and officers is contained in a bridge-house amidships, while the crew's quarters are in the forecastle. In all the accommodation careful attention has been paid to secure complete ventilation for the hot country service for which the new vessel is intended. Immediately after the launch the *Congo* was berthed alongside of the builders' wharf, where the engines will be fitted on board, and the vessel completed ready for sea. The ceremony of naming the new steamer was performed by Miss Kate Wilson, of Glasgow.

M'Allister.—On January 21st Messrs. Blackwood & Gordon launched from their shipbuilding-yard, Port Glasgow, an iron screw steamer of the following dimensions:—200 by 30 by 15, about 1,000 tons, built to the order of Mr. E. M'Allister, for his firm, M'Allister & Co., Singapore. She is to be commanded by Captain J. M. Tullock, R.N.R. As the vessel left the ways she was named the *M'Allister* by Miss Alice Edmonstone, youngest daughter of Admiral Sir William Edmonstone, Bart., of Duntreath Castle. This vessel will be furnished by her builders with compound surface-condensing engines of 110-horse power, and fitted up with extensive saloons, well ventilated. She will form an addition to the M'Allister line of Eastern traders.

Stirling Castle.—On January 21st the screw steamship *Stirling Castle*, of Messrs. Thomas Skinner & Co.'s London and China Line, was launched by her builders, Messrs. John Elder & Co., of Fairfield, Govan, Glasgow, the ceremony of naming the vessel having been performed by Miss Reed, of South Kensington. This fine steamer is 436 ft. in length, 50 ft. beam, 33 ft. in depth, and registers about 4.500 tons gross, and will be fitted by her builders with a set of engines of their well-known three-cylinder type to indicate 7,000-horse power. These engines are constructed to propel the vessel at the rate of 18 knots, so that she is expected to carry the first teas from China to London in the unprecedented short period of four weeks, or perhaps, a little less. Her passenger accommodation is well ventilated, and will be fitted up with every regard to health and comfort, while her appliances for rapid loading and discharging of cargo are unsurpassed. She is to leave the Clyde to load at London for China the last week of February. Immediately after the launch the vessel was towed into the basin at Messrs. J. Elder & Co.'s works to receive on board the boilers and machinery, which are all in readiness at the shears to go on board.

Rover.—On January 21st there was launched from Messrs. Ramage & Ferguson's shipbuilding-yard, at Leith, a new iron auxiliary steam yacht for the Earl of Eglinton. The vessel, which on leaving the ways, was named the *Rover* by Mrs. St. Clare Byrne, of Liverpool, presents many novel features in yacht construction, and will, no doubt, attract much attention during the coming season. The dimensions are:—Length, 175 ft.; breadth, 27 ft. 6 in.; depth moulded, 17 ft.; tonnage, 650; horse-power, 85 nominal; cylinders, 23 and 44 inches diameter by 24 inches stroke. The *Rover* has been built to the design and under the superintendence of Mr. St. Clare Byrne, of Liverpool, and, when finished, will likely start for a Mediterranean cruise.

LAUNCH.—IRISH.

Garfield.—On January 7th a sailing vessel, of very handsome model, named *Garfield*, was launched by Messrs. Harland & Wolff for Messrs. Ismay, Imrie, & Co., of the White Star Line, Liverpool. The *Garfield*, which is built of Siemens-Martin steel, has a full poop, is fitted with cabins for officers, and has a deck house for the accommodation of the crew; a steam winch and boiler, driving winch, and iron masts, with all the other latest improvements, will also form part of the fittings. The newly-launched vessel, which will be completely rigged by the builders, is of the following dimensions:—Length, 292 ft.; breadth, 41 ft. Gross register tonnage, about 2,300; and she has been classed 100 A 1 at Lloyd's. Shortly after the launch, which was accomplished most successfully, the *Garfield* was towed to the crane at the Abercorn Basin for the purpose of having her masts and other equipments put on board—a work which, it is expected, will be accomplished in about a month.

LAUNCH.—FRENCH.

La Ville de Pernambuco.—On January 10th was launched from the shipbuilding yard of Forges et Chantiers, de la Mediterranée, at La Seyne, near Toulon, an iron screw steamer, built for the Compagnie des Chargeurs réunis du Havre. Length between perpendiculars, 294 ft.; breadth, moulded, 35 ft.; depth, moulded, 25 ft.; tonnage, net registered, 1,400 tons. She will carry about 3,000 tons, and is classed at the highest class of Bureau Veritas, under special survey. She will be provided with direct-acting compound engines of 1,000 indicated horse power by the same firm at Havre. Cylinders 34 and 64, with 40 in. stroke. Steam will be supplied from two large cylindrical boilers, with large heating surface, and of superior construction, for a working pressure of 80 lbs. The steamer is to be brig-rigged and spar-decked. She will be fitted with double bottom for water ballast, four steam winches, and all the most recent and improved appliances for expeditious loading and discharging cargoes, patent windlass, and patent steam steering gear. In addition to superior cargo space for the conveyance of general goods. the vessel will be able to accommodate in 'tween decks 30 passengers, with the dining saloon on upper deck and a promenade deck on top. She is fitted as well to accommodate a great number of emigrants. The captain and officers are accommodated in houses amidships. The steamer was christened *La Ville de Pernambuco* as she left the ways. She will form the fifth of a fleet of fine screw steamers ordered by the same firm at Havre.

LAUNCH.—SWEDISH.

Saltholmen.—On January 18th there was launched from the yard of the Motala Company at Lindholmen, a screw passenger steamer, sister ship to the *Hoen*, launched in December last, and built for the same owners, "Det forenede Dampskib Selskab," in Copenhagen. This steamer is of the following dimensions:—Length, 148 ft.; breadth, moulded, 23 ft.; depth of hold from top of keel, 10 ft.; height between decks, 7 ft. 3 in. *Saltholmen* is a very strong-built vessel, the frames being 27 in. apart, with an extra frame in each space, running from keel to above the load line. The hull plating is of extra thickness throughout the whole ship. She will receive engines of 100 nominal horse power.

TRIAL TRIPS.

Sorrento.—On December 31st this screw steamer, built and engined by Messrs. Alex. Stephens & Sons, Linthouse, Govan, to the order of Messrs. R. Sloman & Co., of Hamburg, made her trial trip, and underwent a speed test at the measured mile off Skelmorlie. Six progressive trials were made, the mean maximum speed being 11¾ knots.

Torch. — On December 31st the twin-screw steamer *Torch*, built by Messrs. Robert Duncan & Co., Port Glasgow, for the Clyde Lighthouse Trustees, to be used in connection with their gas works at Port Glasgow and the gas-lit buoys on the Firth, went on her trial trip. The *Torch* ran the measured mile twice, attaining an average speed of about 11 knots, a rate which was considered entirely satisfactory. Thereafter the steamer proceeded to Toward Point, the company on board disembarking and making an inspection of the lighthouse and its appurtenances.

Hindoustan.—On January 6th the screw steamer *Hindoustan* had a very successful trial trip. She has been built to the order of the Maurice & Reunion Company, Marseilles. Her length over all is 322 ft.; breadth, 40 ft.; and depth of hold, 29 ft. 5 in; her carrying capacity, deadweight, being 3,700 tons. The vessel is fitted with Palmer's engines of 300-horse power nominal; the cylinders are respectively 38 in. and 71 in., and the stroke of the piston 48 in. She will take the highest class at Lloyd's. The vessel has extra scantlings, main deck of chequered iron plates, water ballast upon the cellular principle fore and aft, awning deck, Emmerson & Walker's patent steam combination windlass, four steam winches, Bow, Maclachan, & Co.'s patent steam steering gear, and all other modern improvements. Amidships she has a long bridge-house, covering the engine and boiler space, and containing accommodation for the officers and engineers, and she has also first class cabin accommodation.

Virginian.—On January 6th the Atlantic liner, the *Virginian* (s), built and engined by the Palmer Shipbuilding and Iron Company (Limited), at Jarrow, for Messrs. F. Leyland & Co., of Liverpool, was taken out for a trial trip. This vessel has been specially built and designed to meet the increasing requirements of the carrying trade between this country and America, and forms the latest addition made to the liners under the management of Messrs. Leyland & Co. between the Mersey and Boston. The *Virginian* is 435 feet in length over all, by 41 feet breadth of beam, and 29 feet 6 inches depth of hold. She is classed 100 A 1 at Lloyd's, but her scantling is considerably in excess of the requirements of the registry. She has three iron decks, all fore and aft, the upper ⅝ths of an inch in thickness, with edges double, and butts treble rivetted fore-and-aft, and sheathed with pitch pine. Additional care has been taken to give great strength to the bottom of the hull by increased depth of floor plates, and by extra keelsons at the bottom bilges and sides, which are all connected to the shell plating fore-and-aft. The shell plating is of more than ordinary thickness. The weight of each boiler is 80 tons. Seven strong transverse iron bulkheads divide the hull into eight water-tight compartments, and, by way of protection from the Atlantic sea, she has a long turtle backed forecastle, in which is provided comfortable accommodation for the crew and cattle men. Amidships is erected a long iron deckhouse to cover in the saloon and the cabins provided for the use of the captain, officers, and first and second-class passengers; a hood aft, covering the store room and wheel-house, containing Hainson's patent steam steering gear, which will be worked from the wheel-house amidships by means of steel rods and bevel gearing carried aft underneath the upper deck. By way of adding to the sailing powers of the steamer, and as a safeguard to mishap through injury to the machinery, she is provided with four iron pole masts, so that she will be able to carry a large body of canvas. There are sixteen winches on the upper deck, one to each hold; and Emerson & Walker's patent direct acting steam windlass on the forecastle. Excellent provision is made for the easy shipment and discharge of cargo. Provision is also made upon the main and upper decks for the carrying of cattle from America, accommodation being provided for 700 head of cattle. In addition to the live cattle in the vast holds, there is space for stowing upwards of 4,000 tons of general cargo. According to agreement the trial trip was to be a thoroughly trying and efficient run to sea of not less than twelve hours under steam.

She left Smith's Buoys a little before three o'clock in the morning, and shortly after getting out to sea the wind, which had been blowing almost a gale from the westward during the night, rose in strength until it reached a perfect hurricane, at which it continued to blow all day, yet, notwithstanding she was even in light trim for an ordinary trial run of short duration in fine weather, her sea-going qualities,steadiness, &c., were such as to give the utmost satisfaction to all concerned. The run extended to several miles eastward, then northwards nearly to the Farne Islands, and home again to the Tyne, during which the engines yielded even greater results than were anticipated from them.

Sylvia.—On January 10th the *Sylvia*, 4, double-screw surveying vessel, 887 tons, 649-horse power, went out from Sheerness for a six hours' trial of her engines and machinery. She was accompanied by the tug *Sampson*, the precaution of sending her being taken in order that the *Sylvia* might have assistance in the case of any emergency. When near the Red Sand, about twenty miles from Sheerness, the *Sylvia* ran aground. Fortunately the tide was flowing at the time, and after being on the sands for some time she was got off without much difficulty. The trial trip altogether was of a very unsatisfactory nature, the engines priming very much. The *Sylvia* returned to the harbour the same evening, but it is not yet known whether her keel has sustained any damage. The officials of the Medway Steam Reserve were in charge of the ship at the time of the occurrence. Upon the arrival of the *Sylvia* in Sheerness harbour on Tuesday night, a party of fitters were at once sent off to remedy the defects discovered in the machinery during her trial, and to take steps to prevent the priming of the engines. The *Sylvia* was taken out for another trial on Wednesday, which was of a more satisfactory character. She will be taken into dock to have her keel examined, in order to ascertain what damage has been done by her running aground upon the Red Sand.

Jacob Christensen (s.).—This steamer, which has been built by Messrs. Raylton Dixon, & Co., Middlesbrough, to the order of Hans Konow & Co., of Copenhagen, proceeded on her trial trip lately. She is an iron screw steamer, 269 ft. long, 34 ft. 9 in. beam, and 24 ft. 3 in. depth of hold, which gives her a carrying capacity of 2,500 tons on 22 ft. draught. She is built as a three-decked steamer, having main deck of iron and upper of wood. Her water ballast is contained in a large chamber in the main hold, forward of engine room, which is also available for stowage of cargo. She is fitted with a short poop aft, in which are commodious cabins for captain, officers, and two or three passengers. Higginson's steam quartermaster steers her from the bridge, and she is fitted with steam winches and self-reefing topsails. Her engines, of 150-horse power nominal, are by Messrs. T. Richardson & Son, of Hartlepool, and gave every satisfaction on her trial trip.

North Cambria.—On January 21st the new screw steamer *North Cambria*, built at the Howdon yard of Palmer's Shipbuilding and Iron Company (Limited), to the order of Messrs. Hugh Roberts & Son, Newcastle, proceeded from Shields to sea on her trial trip. The dimensions of this vessel are:—Length between perpendiculars, 270 ft.; breadth moulded, 36 ft.; she is depth-moulded 25 ft.; and classed 100 A 1 at Lloyd's. She is intended for the general carrying trade, and has all the requisites for quick loading and the despatch of cargo. She will also carry cattle in the 'tween decks and on the main deck. Her 'tween deck is of iron. She has four steam winches, Emerson & Walker's patent steam windlass, and she is fitted with Messrs. Clarke, Chapman & Gurney's steam steering gear. The engines are fitted with Durham's improved velometer. She has water ballast fore and aft on the cellular principle. Her engines, constructed by Palmer's Company, are of 180-horse power nominal. The *North Cambria* will be commanded by Captain Wm. Evans; she has a speed of 11 knots per hour, and has proceeded to Middlesbrough to load a cargo of iron rails for Galveston.

Orion (s.).—The new screw steamer *Orion*, built by Messrs. Caird & Co., Greenock, for the Austro-Hungarian Lloyd's Steam Navigation Company, proceeded down the Clyde on Wednesday on her trial trip. The *Orion* has been built for the Eastern trade, and is to sail from Trieste. She is a vessel of 2,800 tons, with engines of 2,400-horse power, and, although she has been fitted up more for cargo-carrying purposes, she has accommodation for passengers. There are three decks, the saloon being on the upper, while the cabins are ranged on the under deck. For the purposes of loading and steering all the latest improvements in machinery have been introduced, and the vessel is fully expected to prove a credit to her builders. On board the steamer at the trial trip there were a number of gentlemen who joined her at the Tail of the Bank, which she left for the run down the Firth shortly after 11 o'clock in the forenoon. The engines worked very smoothly during the run. Arrived off Skelmorlie the *Orion* ran the measured mile three times, the speed attained being 13¾ knots, which was considered most satisfactory, the speed contracted for being 12 knots. The engines indicated 2,500-horse power, the revolutions per minute being 65. The steamer, which has been built to the highest class at Lloyd's, gave every satisfaction to all concerned during the trip.

Correspondence.

[*It must be understood that in giving insertion to communications under this heading, we do not in any way pledge ourselves to the opinions preferred therein. We will with pleasure insert any letters likely to benefit our readers, either from their intrinsic value, or as being calculated to promote such discussion as will elicit facts, valuable from their being the result of practical experience.*—ED.]

SEA-GOING ENGINEERS' ASSOCIATION.

To the Editor of THE MARINE ENGINEER.

SIR,—I can scarcely doubt that the following reflections would occupy the mind of every reader of "Landsman's" contribution to the correspondence columns of the October part of THE MARINE ENGINEER. An impertinence that is void of the least pretension to either wit or sarcasm can scarcely be too severely reprehended. Doubtless "Wave" would consider that "Landsman's" sole object in communicating the little information that is contained in his letter was simply that of indulging in a little spiteful growling, and it may be assumed that "Wave" will be grateful accordingly. Beyond the impertinent style of "Landsman's" letter, it contains nothing that entitles it to reply or consideration, since no one would infer from its contents that its writer was a person at all troubled with ideas, or possessed of an intelligence sufficiently keen and clear to enable him to judge of either the necessity, or the acquisition, of improvement in the case of "Sea-going Engineers;" indeed, it may be readily imagined how difficult, shall I say *impossible*, it would be for any solicitor to enrich the mind of "Landsman" with the ideas which he mouths so unnecessarily.

In conclusion, a word of advice may not be amiss to "Landsman," and we should advise that before he again commits himself to print he should take a trip to sea, when he would be relieved by a legitimate discharge of his bile, and probably, when this was accomplished, his head would be all the clearer, and he would be enabled to exercise sufficient judgment to write, at least, a courteous letter.

I remain, Sir, Yours respectfully,
A HULL "SEA-GOING ENGINEER."

CARPENTERS AND SHIPWRIGHTS IN H.M. ROYAL NAVY.

To the Editor of THE MARINE ENGINEER.

DEAR SIR,—Having read the article which appeared in your issue of last month on the Position and Status of our Royal Marine Engineers and Engine-room Artificers, which is to be followed up, I consider an account of the origin, development and requirements of any class such as you are giving most interesting to those who wish to consider the claims at different times set forth by various branches. By the descriptive account you are giving of the Marine Engineers, &c., one can form a clear opinion as to whether they receive the position to which they are entitled or otherwise.

I should like to call your attention to another branch of industry in H. M. Service that should receive immediate consideration. The branch I refer to is the carpenters, carpenters' mates, and shipwrights engaged in H. M. Royal Navy.

It is a fact which cannot be denied that the officers and highly skilled artizans mentioned are, as regards pay and recognition, the worst off in the Service. A carpenter in charge of one of our large ironclads has an amount of responsibility thrown upon his shoulders, which only many years of experience and study can fit him to undertake, and the carpenters' mates and shipwrights must serve an apprenticeship of seven years, and pass a strict examination as skilled artizans and as being well up in all the practical requirements to meet emergencies in any part of the ship.

For a long time past the Government has experienced great difficulty in obtaining properly qualified men to fill these posts. About twenty years ago Government shipwright apprentices were induced to complete the last two years of their apprenticeship on board a man of war, in the hope that many would remain in the Service, and thus improve the class of carpenter in the Navy. This however, failed, as these young fellows would not throw themselves away for the paltry pay then given, especially as they were expected to commence their career as ordinary blue jackets. These Government apprentices, it must be known, passed similar examinations to the engineer students to obtain their first entry in the Service, and continued a course of study in higher subjects during their apprenticeship.

Many of them could design, lay off, make calculation, working drawings, and order material for all classes of vessels.

Since the failure of inducing their own apprentices to join H.M. Service, the Government has instituted schools of instruction for the present carpenters of the Navy, at the different Government yards for the purpose of educating them up to their requirements. If the Government would only give such men as they want, the pay and position their services and knowledge should command, they would soon get plenty of men who would require no educating after joining the Service; and remove what is now a great drawback to that branch of the Service.

I am, Dear Sir,
A LATE GOVERNMENT APPRENTICE WHO TRIED THE SEA.

To the Editor of THE MARINE ENGINEER.

DEAR SIR,—If you would kindly answer the following question in the February number of your valuable paper, I would deem it a great favour. Suppose a steamer being towed or sailing with propeller shaft being disconnected, whether the propeller would have a tendency to go ahead or astern? Trusting you will not deem me too troublesome, and waiting the favour of an early reply,

I am, Dear Sir, respectfully yours,
Liverpool, January 25th, 1882. G. A. R.

[In the case of a ship sailing or being towed with her screw disconnected, the screw would revolve in the same direction as it would in propelling the vessel ahead.—ED. M.E.]

NAVAL AND SUBMARINE ENGINEERING EXHIBITION.

THE large hall at Islington, so noted for the many famous Exhibitions of native progress in nearly every imaginable industry, which one after the other occupy its vast area, will shortly be devoted to the Exhibition of various branches of Naval and Submarine Engineering.

It is a matter of surprise to think that as so many different exhibitions of every kind of manufacture and invention are continually taking place throughout the country, nothing of the kind affecting Submarine Engineering has for many years been undertaken on a scale which would attract special attention. Taking into consideration the vast amount of vested interest and capital engaged in all kinds of Naval and Submarine Engineering in our kingdom, and the high position our manufacturers hold in this special work, it is certain that the forthcoming Exhibition, though novel in its character, cannot but be most successful. The Agricultural Hall will be open to the public from 10 a.m. to 10 p.m. from the 10th to the 20th of April inclusive (Sunday, 16th, excepted), when, from the large number of spaces now taken, visitors will doubtless find the ground floor and galleries completely filled with inventions and appliances, each and all of a highly interesting and novel character.

Mr. Samson Barnett, jun., the originator and manager of this Exhibition, has spared no time, trouble, or expense, to assure the success which apparently awaits the result of this Exhibition. The large list of able and distinguished patrons would form a good guarantee of its value and probable ultimate success. This list contains the names of Earl Ravensworth, President of the Institution of Naval Architects; Lord Alfred Paget; Admiral Sir W. Houston Steward, K.C.B.; Vice-Admiral Henry Boys; Vice-Admiral Arthur W. A. Hood, C.B.; Vice-Admiral Sir J. E. Commerell, V.G., K.C.B.; Rear-Admiral T. Brandredth, A.D.C.; Rear-Admiral F. A. Herbert, Director of Naval Ordnance; Sir Digby Murray, Bart; Sir E. J. Reed, K.C.B., F.R.S., M.P.; Lieut.-Col. Sir William Palliser, C.B., M.P.; Sir Joseph William Bazalgette, C.E., C.B.; Sir W. Thomson, F.R.S.; N. Barnaby, Esq., C.B., Director of Naval Construction; B. Waymouth, Esq., Secretary, Lloyd's Registry of British and Foreign Shipping; J. Abernethy, Esq., C.E., F.R.S.E., President of the Institution of Civil Engineers; J. T. Smith, Esq., C.E., President of the Iron and Steel Institute; C. Horsley, Esq., C.E., F.G.S., F.M.S., President of the Society of Engineers; J. C. Foster, Esq., F.R.S., President of the Society of Telegraph Engineers; A. T. Walmisley, Esq., C.E., President of the Civil and Mechanical Engineers' Society, and Messrs. Maudslay, Son & Field.

It is to be regretted that the International Exhibition of the Worshipful Company of Shipwrights, to be held at the Fishmongers' Hall in May next is not amalgamated with the Naval and Submarine Exhibition. Had this been done, popular attention would have doubly concentrated itself on the combined exhibitions, and each one would have assisted to render the other more attractive. The Worshipful Company of Shipwrights' International Competitive Exhibition of Ship Models and Designs was instituted with the object of obtaining by competition the best design, from all points of view, of different classes of men-of-war, merchant vessels, torpedo boats, yachts, &c., all of specified types, whilst the Naval and Submarine Exhibition embraces sundry mechanical appliances of ingenious device and construction for all kinds of vessels as well as submarine plant and appurtenances for constructing docks, piers, bridges, and other work incidental to Naval Engineering. One of the greatest troubles to the promoters of the former Exhibition of the Shipwrights' Company of 1877 was the miscellaneous section of their exhibits, which did not come under any special type of ship. All branches of this kind would class in the category of the Submarine Exhibition, and some special models and drawings of high-class vessels might be sent to this Exhibition, which would have complied with some class conditions set forth by the Worshipful Company of Shipwrights. Thus both Exhibitions might have been of the greatest use to each other, and visitors to London could have witnessed both in one journey. As the fixtures now stand, one exhibition to take place in April, and the other in May next, intending visitors to each must make two journeys, or a prolonged stay in London.

The exhibitors of the Naval and Submarine Exhibition, at this premature date, are so numerous and so well known in their profession that the success of this Exhibition is completely ensured. The names of some of the exhibitors and their exhibits are as follows:—

The Admiralty: Models of six different types of men-of-war; B. Waymouth, secretary of Lloyd's Registry of British and Foreign Shipping, model of s.s. *Ostrel*, of the Peninsular and Oriental Co.; Messrs. J. Elder, of Fairfield, Glasgow; W. Denny, Esq., of Dumbarton, and Oswald, Mordaunt & Co., of Southampton, models of various vessels of interest. Sir W. Armstrong, models of the Greek alphabetical gunboats; the Inman Line, models of the *City of Rome* and *City of Berlin*; Messrs. J. and G. Thompson, of Clyde Bank Foundry, Glasgow, models of the *Servia*, and other vessels; Messrs. Palmer & Co., of Jarrow, model of large cargo-carrying steamer and *Medina* class of gunboats built for the Admiralty.

Boat-lowering apparatus, life rafts, buoys, disconnecting deck seats, cabins, &c., occupy a large space, and are generally of the most useful and interesting nature. Different kinds of screw propellers and rudders are largely represented. Amongst the exhibitors of wire rope may be noticed the names of J. E. Wright, of Birmingham; Messrs. Felton & Guillaime, near Cologne; the Warrington Wire Rope Co.; Messrs. Binks, Bros.; and Messrs. Bullivant & Co., of 72, Mark-lane, E.C., and Millwall, E. The last-named firm, Messrs. Bullivant & Co., besides samples of their exceedingly light, strong, and highly flexible steel wire ropes and cables, exhibit also their winding reels or winches, patent nippers, torpedo nets, floating anchor, and lifting barge. Under the heading of novelties may be noticed the boat built by Peter the Great during the time he lodged at Sayes Court, adjoining the Royal Dockyard, Deptford, and the First Navy List; a boat 9 ft. in length, which will be kept running in the large tank by means of liquid fuel; a 1,000-horse power rotary marine engine by Brossard, of Swansea; and drawings and models of a marine surface-condensing engine, worked for fifty years successively by the superintendent marine engineer of the Netherlands.

Refrigerating and condensing apparatus are numerously represented, as also are nautical instruments, diving apparatus, steam, hydraulic, and hand steering gear and anti-fouling compositions.

Many models of well-known sailing yachts will be exhibited; also a full-sized steam launch, with machinery by Messrs. Forrest.

The Kirkstall Forge Co.; the Leeds Forge Co.; Messrs. Hall, of Dartford; Messrs. Tangye; Messrs. Fielding & Platt; Messrs. Siebe & Gorman; and Messrs. Stone, of Deptford, with many other exhibitors too numerous to name, make up a list of names of the best known manufacturers.

Viewing the present prospects of the Exhibition, it may well be considered in a highly satisfactory state. It only remains to be proved whether our naval manufacture will attract as large an amount of attention as other branches of engineering industry; if so, and it is impossible to understand why such should not be the case, the Naval and Submarine Exhibition of April, 1882, should be a great success from every point of view.

EDITORIAL NOTES.

THE Americans are never satisfied until they have produced whatever they take in hand on a gigantic scale. They are now perfecting the construction and increasing the size of their well-known paddle river boats, and are applying them for passenger and freight traffic on the outer rounds of the coast about Long Island and New York. One of the last iron steamers, built for this purpose by the Harlan and Hollingsworth Company, Wilmington, Del., has a registered tonnage of 2,485 tons, and is thus the largest vessel of her class afloat. She is called the *City of Worcester*, and is 340 feet over all, with hull beam of 46 feet, but with a breadth of 80 feet over the guards, the depth of hold being 16·3 feet. She has three stories, or tiers, of state-rooms on the forward deck, and two on the afterdeck, with a hurricane deck as promenade above. The arrangements for the safety of the passengers and crew are very complete. Besides the plentiful supply of lifeboats we are glad to see that no less than four life rafts besides many life buoys form a part of her equipment. Every berth is provided with Kaukweiler's never-sink cork life jackets, and these are also plentifully distributed to the deck passengers and crew, amounting in all to the number of 800. Every precaution has also been taken against fire. There are nine fire plug outlets on the main deck, eight in the saloon, four in the hold, and four on the hurricane deck, all supplied from two large pumps driven by a donkey engine. In the matter of lighting, too, this vessel will take an advanced position. She is specially laid out for electric lighting with 100 Edison lamps. A 20-horse power engine is especially provided to drive the generator for these lamps. She is also governed by steam steering apparatus, operated in the pilot house. The fittings and joiners work, as may be imagined, are exquisite, and the whole vessel is really a triumph of naval architecture and engineering skill.

THERE seems to be somewhat of a mania for constructing tunnels under water ways, channels, and rivers. In addition to the projected Channel Tunnel of which so much is now heard, the Hudson River tunnel, is an undertaking of no small difficulty and magnitude; and we hear that a new tunnel was just being decided on under the St, Lawrence River at Montreal, Canada. The contract has just been taken by J. B. Bouilliard for 3,500,000 dollars, the work to be finished in 1885. Permission has also been granted by the Italian Government to the Venetian Society of Construction, to make the necessary preliminary investigations for a tunnel under the Straits of Messina between Italy and Sicily. The rock to be traversed is extremely hard, and a stratum of 120 feet of rock will be left between the top of the tunnel and the sea. The approaches to the tunnel at either end are to be made by spiral tunnels.

TORPEDO boats will soon form a most important item in the naval armament of all maritime powers. A great deal of ingenuity will, however, be required in their construction before they can enter the lists against ironclads with any chance of success. At present, in a dark night they are, when unexpected, a dangerous foe; but if rendered conspicuous by daylight or the electric light, they are exceedingly vulnerable. A few well-directed bullets below or about water-line from the Nordenfelt or Hotchkiss gun will suffice to admit the water, and thus rapidly to disable the boat—as a rule, a few inches of water in the stokehole will suffice to put out the fires. We understand that some torpedo boats have already been made for the Italian Government in which a special arrangement is fitted by Messrs. Yarrow, so that the sudden admission of water to the hold or stokehole of the boat shall be prevented from entering the fire-box and extinguishing the fire. A boat with the new fitting would be able to retain its steaming power for five honrs, even after the stokehole had been flooded, and thus ample time for escape would be given. It is rather odd, and somewhat discreditable to the Admiralty, that Foreign Governments should always thus obtain the benefit of English private ingenuity before our own. We think that the adaptation of such a fitting to the furnaces of all steamers would be most valuable as a protection against the disabling effect of sudden swamping.

AN American so-called accelerating gun is attracting a good deal of attention on the other side of the Atlantic. It is well known that the action of gunpowder by explosion is very sudden in its action upon the projectile, and confined in its operative effects almost entirely to the breach of the gun. That is to say, the expansive force of the gunpowder almost entirely falls off before the shot has travelled through a small portion of the barrel. This is shown by the excessive strength which it is thus necessary to give to the breech of our large guns and the comparative slightness of the other part of the barrel. Sudden and explosive action upon a shot is far from being a good method of producing a high velocity. Speed can only be acquired by a heavy body gradually, and after the movement through an appreciable distance. The accelerating gun referred to endeavours to realise these views by spreading the effect of a succession of charges over a considerable length of barrel. The bore is provided with a series of pockets, each containing a separate charge of gunpowder, which are ignited successively as the shot passes. The shot is thus put gradually into motion, and each successive charge keeps up a constant accelerating pressure throughout the whole travel of the shot in the gun. The result is, that the maximum pressure in the breech is very much reduced as compared with the present system, whilst the final velocity is very much accelerated. Guns on this system can be built at about half the weight for equal penetration, compared with those of the present system.

THE Royal Naval Engineers are again endeavouring to draw attention to the very obvious injustice of their position, by means of a pamphlet, which very clearly and temperately sets forth the grievances under which they suffer. It is difficult to imagine any reasonable ground why the naval engineers should be placed in a worse position as to increase of pay now than was their case some twenty years ago. The mechanical appliances on board our ironclads are increasing in number and importance from year to year, and the success, or otherwise, of any naval engagement would depend more than ever upon the successful operation of the mechanical appliances, and consequently upon the skill and readiness of the engineers in charge. It is truly "hard lines" that, after seventeen years' service the pay is only 11s. per day, instead of 13s. as in 1863, and after twenty-six years only 14s. to 16s., instead of 18s. as formerly. Apart from these substantial grievances, those more sentimental ones of rank and relative position as to the other naval officers will be not the less galling to the feelings of those gentlemen who compose the engineer department. It will be impossible much longer to refuse the proper social and monetary recognition to that branch of the naval service, which is now certainly most necessary. We can imagine an engineer officer fighting an ironclad in the case of the disablement of the naval officers, but we cannot imagine the engines being worked or rapidly repaired by the naval officers in the absence of the engineers.

THE PROPOSED NEW LINE OF ATLANTIC STEAMERS.—A Bill was introduced in Congress on February 8th, authorising the Postmaster-General to contract for and establish a weekly mail steamship service between Fort Pond Bay, Long Island, and Milford Haven, by means of a line of iron and steel screw steamers, capable of making at least 18 miles an hour, to be wholly of American construction, and to be allowed to carry only passengers with their luggage and the mails. The compensation for the mail service is to be $12,500 for each outward-bound trip made within six days, $10,000 for each trip made within seven days, $7,500 for each trip within seven and a half days, and $5,000 each for more than seven and a half days. The Government is to have the right to take the vessels for its own use in case of war of payment of not more than the cost. As without freights the steamers ought to be able to make weekly trips, they would be able to earn $25,000 per year, which would be a handsome subsidy. Fort Pond Bay is at the extreme eastern end of Long Island, about a hundred miles from New York, and is easily accessible by the Long Island Railway, which can be easily extended to the Point. The applicants for this subsidy are the same capitalists with whom Mr. William Pearce, of Messrs. Elder & Co., was in consultation during his recent visit here.

ERICSSON'S TORPEDO.—The Ordnance Bureau in the American Navy Department who conducted the recent experiments with Ericsson's Torpedo Boat Destroyer have reported to Congress that the projectile is of the most formidable character, and within a limited range is superior to anything of the kind. Admira Porter says, however, that while torpedoes of this kind are powerful adjuncts for harbour defence, they are nothing more, and thinks no torpedo can do away with the necessity of building heavy ships.

NOTICE.—Owing to great pressure on our space, we are obliged to hold over the article on "Our Royal Marine Engineers and Engine Room Artificers" until our next issue—ED. M.E.

* OCEAN STEAMSHIP MACHINERY.

A SERIES OF PRACTICAL PAPERS ON THE DESIGN, CONSTRUCTION, AND MANAGEMENT OF THE MACHINERY OF STEAMSHIPS.

By H. Holt-Butterfill, Marine Engineer.

Continued from page 225.

I.—The Problem of Ocean Steam Navigation.

VESSELS propelled by paddle wheels to which motion was given by the application of steam-power, had up to within nearly half a century ago been successfully employed in river and lake service, and on coasting voyages, both in Great Britain and America and on the continent of Europe. But had any person at that period ventured to assert that a steamship could be constructed to propel herself across the Atlantic, a distance of 3,000 miles, carrying fuel sufficient for the passage, a cargo that would be remunerative, and provisions and stores enough for her passengers and crew, he would in all probability have been deemed a philosophical dreamer, and not worthy of attention. Yet the possibility of such an achievement formed, about this period, the subject of very warm debate; and it is reported of a learned philosopher of that day that he declared that one might as well think of making a voyage to the moon as to think of ever getting to New York by steamship; that it was in fact an *impossibility*.

The solution, however, of this—at that time—knotty problem was destined soon afterwards of early accomplishment, thanks to the enterprise of a few British and American merchants, the skill of English and Scotch engineers and shipbuilders, and the courage and good seamanship of two lieutenants of Her Majesty's Navy.

In the year 1837 there was built to the order of the St. George's Steamship Company, by Messrs. Menzies, of Leith, a wooden paddle-wheel steamship called the *Sirius*. She was 178 feet long, and about 750 tons burden. Her engines, which were made by Messrs. Wingate & Co., of Glasgow, were a pair of the side lever type, and of 270 horse-power collectively.

About the same date, Mr. Paterson, a well-known shipbuilder of Bristol, was building to the order of the Great Western Steamship Company, of that city, a wooden paddle-wheel steamship called the *Great Western*. She was 236 feet over all, 36 feet beam, 23 feet deep, and of 1250 tons burden. Her engines, which were also a pair of the side lever type, were of 440 horse-power, built by the subsequently noted firm of Maudslay & Field, of London.

The boilers of these vessels were of the then prevailing type for marine purposes, viz., *flue* boilers, or those in which the heat was communicated to the water by means of a winding flue passing through it, and which conducts the smoke and heated gases to the funnel. Economy of fuel being of vital importance in this first attempt to accomplish the Atlantic passage by steam, great care was taken by the Messrs. Maudslay & Co. in the design and construction of the boilers of the *Great Western*.

The *Sirius*, chartered by the British and American Steamship Company, and under the command of Lieut. Richard Roberts, R.N. (afterwards lost in the ill-fated steamship *President*), started from Cork (now Queenstown) on the 4th April, 1838, and after burning all her coals—about 400 tons—as well as all combustibles in the shape of wood, tar, &c., on board, barely succeeded in reaching Sandy Hook—20 miles below New York—by midnight of the 22nd. Coals were sent to her from New York, and she anchored in that harbour about noon of the 23rd April, 1838.

The *Great Western* under the command of Lieut. (now Admiral) James Hosken, R.N., left Bristol on the 8th April, 1838—four days after the *Sirius* left Cork—and arrived in New York about two hours after the *Sirius*, having 80 tons of coal still on board, or sufficient for two or three days more steaming.

The *Sirius* was taken off the line after a second voyage, but the *Great Western* kept it for several years, and was in fact the successful pioneer of the Atlantic line of steamships.

The arguments against the commercial feasibility of such a traffic as that proposed to be established between Great Britain and America by means of steamships in competition with sailing vessels, were, by the successful voyages of the *Sirius* and *Great Western* practically demolished, and from that time to the present the development of ocean steam navigation has been continuously progressive. A gradual increase has been made in the size and speed of steamships, and their capabilities for performing long ocean voyages practically assured.

Two years after the pioneer voyage of the *Great Western*, the Cunard company was formed, and the *Britannia* built and engined by Messrs. R. Napier & Sons, of Glasgow, a paddle wheel steamer 207 feet long, 34 feet broad, and 22 feet deep, fitted with side lever engines of 405 horse-power was placed on the line to New York. She was soon afterwards followed by other vessels of the same Company of larger size and greater power.

Up to the advent of the *Persia* and *Scotia*, which were built of iron, all the preceeding vessels were of wood. The *Scotia*, launched in 1861, which was the last of the paddle-wheel boats of the Cunard Company, was an iron vessel 366 feet long, 47 feet 6 inches broad, and 30 feet 6 inches deep, her tonnage being 4050, or about 5½ times that of the first mentioned steamer, the *Sirius*.

Although the *paddle-wheel* had been adopted as the propelling instrument in all the foregoing Atlantic steamships, another means of propulsion for large vessels, viz., the *screw propeller*, was rapidly growing into favour with steamship owners. And here again the same persons, the owners of the *Great Western* steamship were the first to make trial of it on a large scale. For this purpose they (1843) commissioned a noted engineer of the time, afterwards Sir I. K. Brunel, C.E., to design for them a ship called the *Great Britain*, to be made of iron, and to be fitted with a screw propeller as her means of propulsion. She was built at the G. W. S. Company's own works at Bristol, under the inspection of Mr. Paterson (the same gentleman who designed and bulit the *Great Western*) and a Mr. Guppy. She was 322 feet long, 50 feet broad, 32 feet deep, and 3000 tons burden, and was fitted with two geared engines of 1000 horse-power, collectively driving a wrought iron propeller of 6 blades, 16 feet diameter. This vessel after being brought round from Bristol to London, where she was exhibited at Blackwall for some time, finally sailed under the command of Lieutenant J. Hosken, R.N., from Liverpool for New York on the 26th July, 1845, where she arrived after a passage of nearly fifteen days, her average speed being a little over 9 knots an hour. This, in every respect, wonderful vessel for her time was, we believe, the first screw propelled steamship that had ever attempted the Atlantic passage. An American ship called the *Savannah* had, it is true, some 30 years previously essayed to make the passage from New York to Liverpool with a *so-called* screw propeller, but actually sailed nearly all the way and did not attempt any further experiments.

---

* The Author reserves the right of re-publication and translation of these papers.

Two new lines of steamships to ply between Liverpool and New York commenced running in 1850. One was the Collins line of American steamers, their first vessel on the route being the *Arctic*, a wooden paddle wheel vessel, and the other, the now famous Inman line, their first ship being the *City of Glasgow*, an iron screw steamship of 1600 tons burden. She was 227 feet long, 32 feet 6 inches broad, and 24 feet 6 inches deep, fitted with geared beam engines of 380 horse-power, driving a propeller 14 feet diameter.

Although the Collins line of steamers have long ceased running, they were the means of a faster and more powerful class of English steamers being put on what has since acquired the name of the "Atlantic Ferry." The rival line, the Cunard had previously made the *outward* passage in 297 hours, and the *homeward* one in 275. When the American steamers were put on, the *outward* passage with them averaged 272 hours, and the *homeward* one 263 hours.

To compete successfully with these, a larger, more powerful, and better appointed class of vessels, of which the *Persia* was a type, was put on from the English side. This typical vessel was a splendid specimen of an Atlantic liner of her day. Her hull and machinery were the perfection of workmanship. Her engines, of the same type as fitted in all the previous Cunarders, viz., side levers, had cylinders 100 inch diameter and 10 feet piston stroke, and indicated 3600 horse power, with which she attained an average speed of nearly 13 knots, and made the passage between Queenstown and New York in 10½ days.

At the date (1856) of the building of the *Persia*, *iron* had for steamers of large size entirely superceded *wood* as a material of construction, and the *screw* as an instrument for their propulsion had also to a very large extent taken the place of the *paddle wheel*. But there were other causes at work which helped to render large wooden paddle wheel steamships unfitted for the Atlantic or other ocean service.

To provide for cases of heavy weather on the passage out or home it was necessary that the vessels on this service should have a sufficiency of coal-bunker capacity. The consumption per day of such vessels as the *Persia* averaged from 130 to 150 tons, and for an average run of 10½ days, at a mean of 140 tons per day, this would require coal-bunker space for nearly 1500 tons. This together with that occupied by the class of engines and boilers fitted to the *Persia* would be so great that she would be unable to carry any weight of cargo without immersing her paddle-floats too deeply, thus putting her in unfavourable competition with other vessels capable of carrying greater weights at a higher speed on the same draft of water. Another drawback to the continued use of wooden steam vessels of large size was found in the difficulty of making them of sufficient strength to withstand the heavy strains to which large ships are subjected in such seas as are met with in the Atlantic and other oceans.

Up to the time (1856) of the building of the *Persia*, the ratio of length to breadth of most of the wooden steamships did not in any case exceed 6¼ to 1; but on the introduction of iron, as the, material of construction, it was found that practically there was no limit to the length of a ship, and that her strength could be made to suit almost any requirements so long as the scantling of her frames and plating, &c., was kept within the possibilities of manufacture and subsequent manipulation while building. Thus, the length of the *City of Glasgow*, of the Inman line, built in 1850, was equal to seven times her beam, and that of the *Persia*, built in 1856, to nearly eight times her beam; this proportion in the still more recently built vessels continuing to increase.

The first screw-propelled ship of the Cunard line was, we believe, the *China*, her dimensions being, length, 326 feet 2 inches; breadth, 40 feet 4 inches; depth, 27 feet 6 inches; and gross tonnage, 2638; her engines being of 420 horse power.

The commercial feasibility and practical accomplishment of the Atlantic passage in 1838 by the *Sirius* and *Great Western* was no doubt the incentive to the formation of the West India Mail Steam Packet Company, who commenced running a class of paddle-wheel steamers similar to the *Great Western* and *Britannia*; their first vessel leaving Southampton in 1841. Some of the earliest of these vessels were, we believe, built at Northfleet Dockyard, on the Thames, by the then noted wooden shipbuilder, Mr. William Pitcher.

Now, from 1838 to 1856, nearly all the then existing ocean steamships, both screw and paddle wheel, laboured under the great disadvantage of being fitted with the old type of low-pressure jet-condensing engines and flue boilers, a type to which, at the later date, all the older firms of engine builders, as well as the marine superintendents of the steamship companies, seemed persistently to adhere, notwithstanding the very great improvements which had then been made in steamship machinery by one or two rising firms of marine engineers.

(*To be continued.*)

MESSRS. MERRYWEATHER & SON'S PATENT STEAM FIRE ENGINE, FOR FIRE FLOATS, STEAM TUGS, SHIPS OF WAR, &c.

ONE of the greatest disasters it is possible to imagine is that of a destructive fire, involving, as it does, serious loss of property and endangering human lives. Both on land and sea a fire of any dimensions causes an inconceivable amount of horror and misery. In the case of a fire on land, if in one of our large towns, plenty of assistance is very soon obtained; if in an isolated part of the country, should it become impossible to save the burning pile, the occupants, in nearly every instance, are enabled to reach "terra firma," and escape with their lives. On the other hand, should a serious fire take place on board ship at sea, the work of extinguishing the conflagration rests solely with the crew and the appliance with which the vessel may be fitted. No help can be obtained from any quarter, and should the mariners be unsuccessful in mastering the flames, which spread with such rapidity on board ship, not only is a costly fabric and valuable cargo entirely lost, but in every probability the whole of the crew either sacrificed in the flames, or swallowed up by the sea.

Many are the causes by which vessels of all descriptions are rendered liable at any moment to an outbreak of fire. The accumulation of gas in the coal bunkers, or in the holds of vessels laden with coal, the effect of damps or heavy working of the vessel on some cargoes, the improper storage of inflammable spirits, and the danger of being struck by lightning, are a few of the causes of fire on board ship which cannot always be avoided. The costly floating machines of men-of-war of the present day are also liable to being fired by one of the many modes of attack invented to destroy an opponent by means of burning. Again, should a vessel be lying in dock in close proximity to other valuable vessels and cargoes, or perhaps with her lofty spars and above-deck fittings overlapping storehouses containing bonded stores of fabulous value, a fire breaking out in this vessel, which could not be checked with the greatest promptitude, might work fearful havoc and ruin. Considering the immense value of our ocean-going vessels, with their machinery and the cargoes they carry, it is one of the chief duties of the shipbuilder, ship owner, and naval architect to provide the best possible means of coping with an agent so destructive to life and property.

Amongst the different inventors of fire engines and fire extinguishers for use on sea or land, Messrs. Merryweather and Sons have for many years held a leading position.

Figs. 1 and 2 on the illustrated page show a longitudinal section and plan of a twin-screw steam launch fitted with a steam fire engine of "Merryweather's Admiralty Pattern," as supplied to the Admiralty for the Royal Dockyards, and to the French, German, and other Foreign Governments. The launch is 45 feet in length, 8 feet beam, with a draught of water of 2 feet forward, and 2 feet 10 inches aft, and a total depth of hold of 4 feet 6 inches. The propelling engines are two in number, each working a gun-metal screw, 28 inches in diameter. The cylinders are each 5¾ inches in diameter, with a 6-inch stroke, the number of revolutions on trial were 280 per minute, and the steam pressure 75 lbs. per square inch. These engines work independent of each other in order to facilitate the manœuvring of the launch amongst shipping. The speed attained averaged over ten miles per hour.

The boiler is on the Field principle, and is arranged to drive the propelling engines and steam fire engine simultaneously, in order that the launch, by acting as a tug, may be engaged in towing a burning vessel away from surrounding shipping, &c., at the same time pouring jets of water on the flames.

This boiler contains 426 Field tubes, giving 236 square feet of tube surface and 35¼ square feet of firebox surface. It also has a large water and steam space—steam can be got up to 75 lbs. pressure in the space of 10 minutes. It is fed by feed pumps attached to each propelling engine, by another long-stroke feed pump on the fire engine, also by an arrangement by which the whole supply of the fire engine pumps, 11·6 gals., can be forced into the boiler by one stroke, and, lastly, by a Giffard's injector. The steam fire engine, whilst limited in weight and space, is of sufficient strength to stand the rough usage to which such machines are usually subjected. The pumps have a steady stroke of 24 inches. There is no dead point in the course of the pistons, and the engine will start with the latter at any position in their stroke as soon as steam is turned on. The engine can be worked at full speed or any intermediate speed, in the event of a limited supply of water, even as slow as one or two strokes per minute. The pumps are arranged to throw water combined with mud, seaweed, shavings, or gravel, the valves being specially adapted for this purpose. The pumping power is very great, being 1,000 gallons per minute through a jet 1¾ inches in diameter to a height of 212 feet. It is arranged to pump four jets, each 1 inch in diameter, which can be thrown to a horizontal distance of 200 feet. These pumps are fitted with suitable connections for pumping out the holds of sunken vessels at the rate of 1,200 gallons per minute. In the fore part of the vessel is a cabin with sleeping accommodation for several firemen if necessary, and at the after part is a large hose-reel which will carry some thousands of feet of fire hose.

Figs. 3, 4, and 5 show enlarged views of the pumping engines of the float or launch. In Figs. 3 and 4 the pumping engines are fixed on a stont angle iron frame, which may be fitted to any steam vessel, and worked by an attachment to the main boiler.

The valves, which are of gun metal, are suitable for pumping foul water, as explained in the description of the steam launch fire engine, without fear of being choked. The engine is arranged for fire purposes, with four outlets as shown, but for general pumping purposes only one outlet is attached of large diameter. In raising the *Eurydice* 11 inches of water was pumped

MERRYWEATHER & SONS' STEAM FIRE ENGINE.

from the hold in five minutes by means of one of these pumps. Fig. 5, shows the pumping engine fixed on a bed-plate of cast iron.

It will be noticeable that these engines have no cranks or fly-wheels. They work with a long steady stroke, thereby reducing the wear and tear; the valve motion is worked by twisted bars as shown, and the pistons are cushioned by the full pressure of steam at the completion of every stroke, on this account it is impossible for the pistons to strike the cover, even when in the most unexperienced hand. The valve motion is so constructed that the engines will start in in any position.

From the foregoing descriptions of the extensive ravages to which vessels and cargoes are rendered liable in case of fire, it will be seen that a steamer fitted with a fire engine of this kind is prepared at any moment, and under any pressure of steam, to bring a most effectual extinguisher to operate on any fire that may break out, and, on the other hand, in the case of a vessel by any means being in a leaky condition, the amount of water that can be thrown out of the hold per minute, would keep her afloat when no other means would prevent her from sinking. The saving of wear and tear on the crew, which is always a great strain on them in pumping out a leaky vessel, is also a great consideration. Vessels fitted with this appliance might in foreign ports, where a fire frequently destroys the greater portion of a town if lying alongside wharves, be most instrumental in checking the progress of the flames. Men of war would reap a great advantage by being able to extinguish any outbreak of fire either in peace or war, or to keep under water entering the ship from any number of ordinary leaks. In the case of steam launches or fire floats fitted with Merryweather's Admiralty Pattern Fire Engine, they are most useful adjuncts to any fleet, and also of the greatest assistance in extinguishing fires which take place in towns near the banks of rivers. The examples of the immense service, rendered at different times by fire floats on the river Thames, would fully exemplify the usefulness of fire engines afloat.

At the same time the Stationary Steam Fire and Pumping Engine as illustrated in plan Fig. 3, in elevation Fig. 4, and a general view in Fig. 5, besides being of great use on board ship is also extensively used for mills, waterworks, mining, sewage and other general purposes for use on land.

The many advantages combined in this fire engine for service either afloat or on shore, is a great step towards securing a tolerable amount of safety from the dreaded ravages of fire, and also provides a ready pumping medium for many different purposes which alone is of the greatest use and value.

LAUNCHES AND TRIAL TRIPS.

[*We have to thank several correspondents for the valuable assistance they have rendered us by forwarding manuscript and newspaper accounts of launches, trial trips, etc. We wish to make this feature of* THE MARINE ENGINEER *as complete and reliable as possible, and will thankfully receive all such information, or accounts of any novelties relating to any branch of the marine engineering trades. To ensure insertion, all such favours should be in our hands by the 23rd of the month.*—ED.]

LAUNCHES.—ENGLISH.

Friary.—On January 21st, from Deptford-yard, Sunderland, Mr. Laing launched a steamer of about 4,000 tons capacity, classed 100 A 1 at Lloyd's, designed expressly for the regular line between Plymouth and New York, owned by Messrs. Jones, Brothers & Co., of Newport (Monmouthshire). On leaving the ways she was named the *Friary* by Miss Swainston, of Sunderland. The vessel has three decks, and has been built with unusual strength and special fittings for the American and Indian trades. She will be supplied with engines of 280-horse power by the North-Eastern Engineering Company, and with all equipments of the most improved character. Her length is 295 ft.; breadth, 38 ft.; and depth, 27½ ft. Mr. Laing is also building another vessel for the same line.

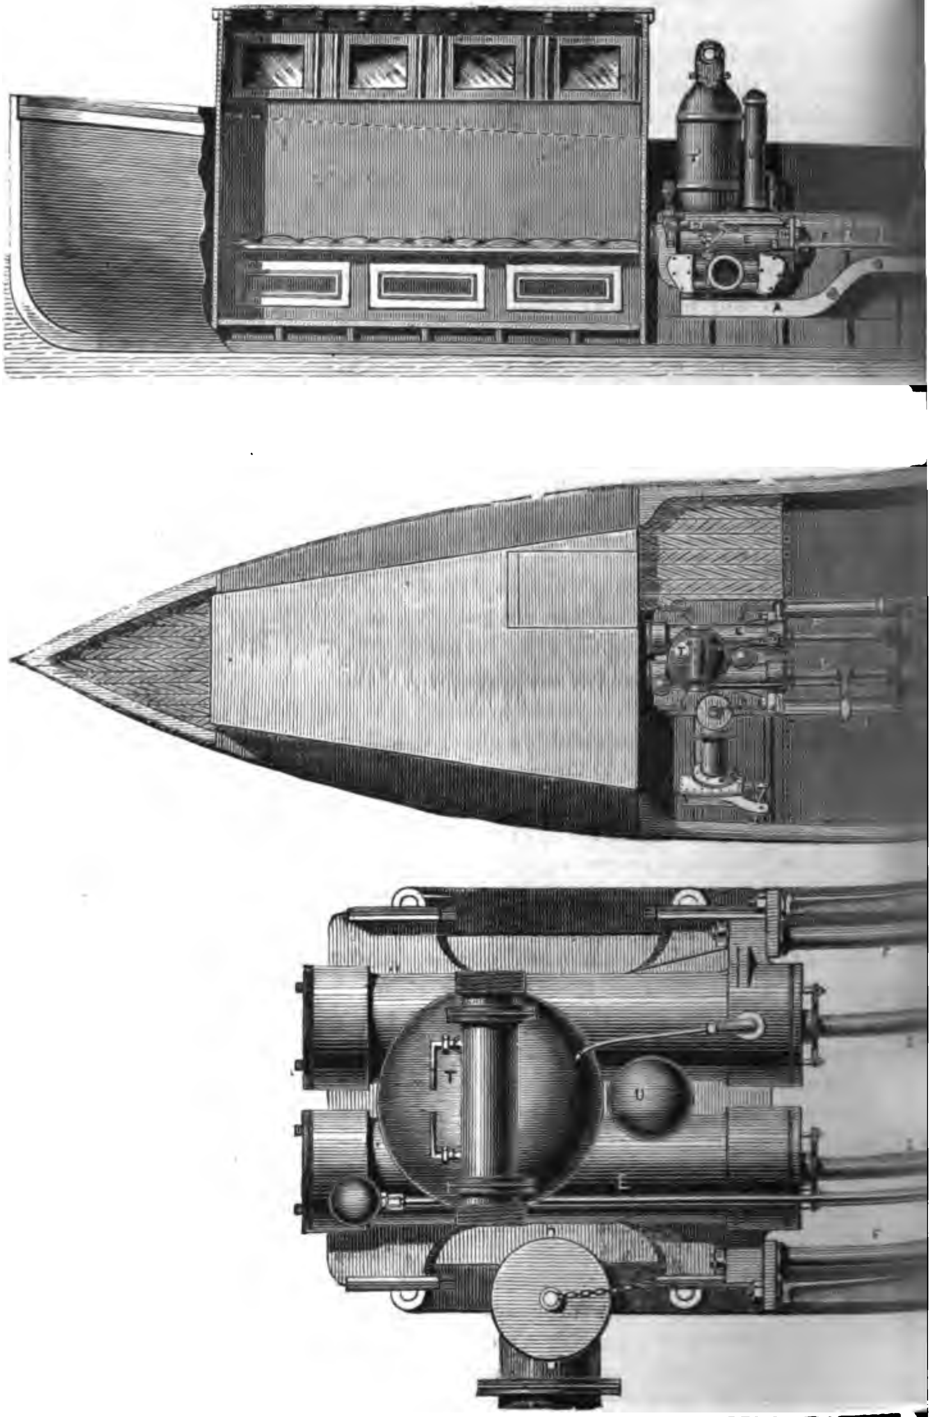
Orialla.—On January 25th Messrs, Thos. Royden & Sons, Liverpool, launched from their yard the *Orialla*, of 1,780 tons, built to the order of Messrs. Sandbach, Parker & Co., and to class 100 A 1 at Lloyd's. She is an iron vessel, and her dimensions are as follows:—Length, 245 ft.; breadth, 40 ft.; depth, 23 ft. 3 in.

Drachenfels.—On January 28th there was launched from the yard of the Sunderland Shipbuilding Company (Limited) an iron screw steamer, built for the Hansa Steam shipping Company, of Bremen. The vessel is built on the three-decked grade, with poop bridge and forecastle, and will take the highest class at Lloyd's, and also at Veritas, with extra strength above their requirements. Both main and upper decks are of iron. She is fitted with water-ballast fore and aft on the cellular principle, and has four steam winches, Harfield's patent capstan windlass, Bow, M'Lachlan & Co.'s hand and steam steering gear, and all the latest improvements for rapid economical working. The steamer is to be rigged as a brigantine, and has accommodation beneath the bridge amidships for the officers, while a saloon aft is provided for passengers. Her dimensions are:—Length, 310 ft.; breadth, 37 ft. 6 in.; depth, moulded, 25 ft. 9 in. Gross tonnage about 2,200, and is provided with engines of 200 nominal horse power, with large boilers, and all the latest additions in marine engineering, by Messrs. Black, Hawthorne & Co., of Gateshead. On leaving the ways she was named *Drachenfels* by Miss Robinson, daughter of Mr. W. S. Robinson, solicitor, Sunderland.

City of Bristol.—On January 31st Messrs. Edward Withy & Co. launched from Middleton Ship Yard, West Hartlepool, a finely modelled iron screw steamer, named the *City of Bristol*, which has been built to the order of Messrs. Palgrave, Murphy, & Co., of Dublin and London, under the inspection of their marine superintendent, Captain R. Carnegie. Her principal dimensions are:—Length between perpendiculars, 235 ft.; beam extreme, 32 ft. 6 ins.; depth moulded, 18 ft. 1 in. She has double bottom all fore and aft on the "cellular" principle, long full poop, topgallant forecastle, iron main deck, 'tween deck in each hold, four steam cranes, one winch, and Higginson's patent steam quarter master. She will class 100 A 1 at Lloyd's, and will have Board of Trade Passenger Certificate, being fitted for the accommodation of first class passengers. Her engines are 150 nominal horse-power, and will be supplied by Messrs. T. Richardson & Sons, of Hartlepool Iron Works. These are the twelfth pair of engines supplied by the same builders, and are expected to give the steamer a speed of 11 knots.

Paolo.—On February 1st there was launched by Messrs. S. P Austin & Son, Wear Dockyard, Sunderland, an iron screw steamer. named the *Paolo*, built to the order of Messrs. A. C. de Freitas, of Hamburg, under the superintendence of Mr. Petersen. She is of the following dimensions, viz.:—Length over all, 233 ft.; extreme breadth. 32 ft.; depth of hold, 16 ft. 6 in.; gross tonnage, 1,100 tons; nett, 700 tons; coustructed with long break, bridge house, and topgallant forecastle, iron decks. She will be fitted with compound surface-condensing engines by Mr. George Clark, Southwick, of 120-horse power nominal, and will be provided with Emerson & Walker's patent windlass, three steam winches by Clark, Chapman & Gurney, and all the latest improvements.

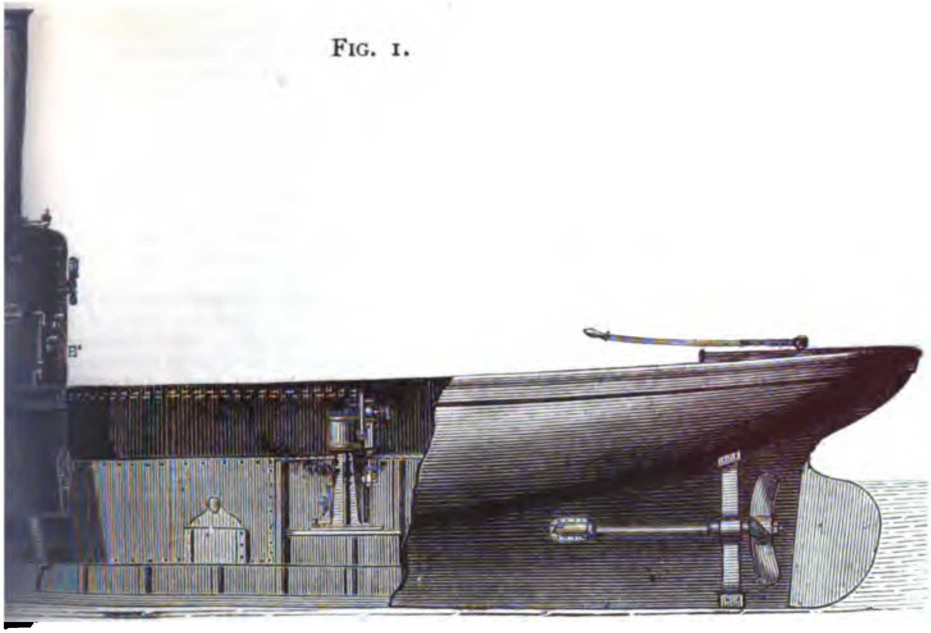
Socrates.—On February 2nd there was launched by Messrs. C. S. Swan and Hunter, Wallsend, an iron screw steamer of 3,000 tons burthen, for the Atlantic and East Indian trades. The vessel

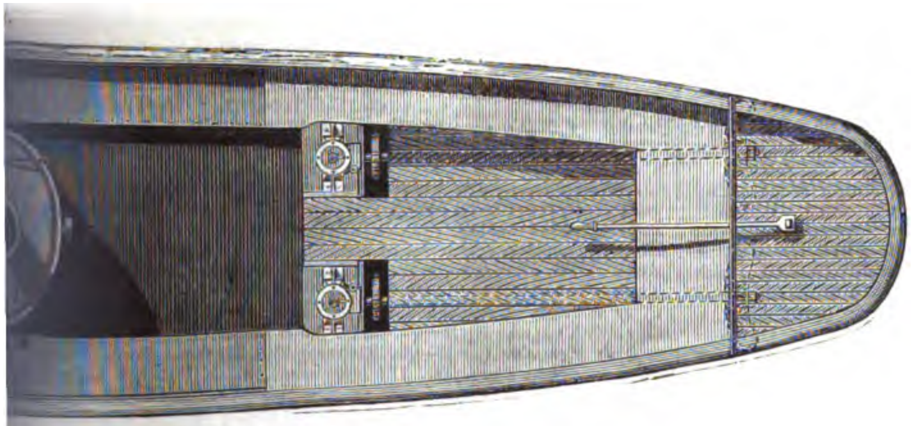


LONGITUDINAL SECTION.

MERRYWEATHER & SON'S PATENT

FIG. 1.





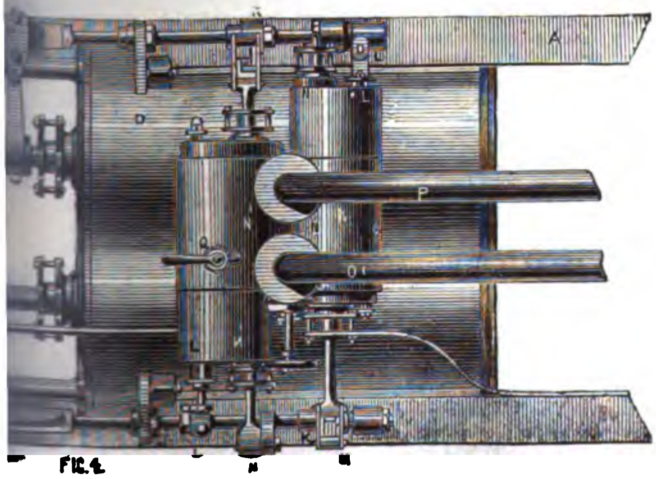


FIG. 4.

[FIRE ENGINE.—(*For Description see Page* 262.)

was named the *Socrates, pro tem.*, and will be fitted with engines of 250 nominal horse power, by Messrs. R. H. Hawthorn, Newcastle.

Joseph Arbib.—On February 2nd there was launched from the yard of Messrs. Raylton, Dixon & Co. an iron screw steamer, built to the order of Messrs, J. Arbib & Co., of London. Her dimensions are :—Length over all, 279 ft.; breadth, 35 ft.; depth of hold, 24 ft. 3 in.; and her deadweight capacity will be about 2,700 tons. She is built on the three-deck rule, with main deck of iron, water ballast in main and after holds, with poop aft for accommodation of officers and passengers, a bridge, with accommodation houses underneath, steam steering gear, and all the latest improvements in this class of vessel. Her engines will be 170-horse power, by Messrs. T. Richardson & Son, of Hartlepool. The vessel and engines have been built under the superintendence of Mr. Casey, who was present on behalf of the owners at the launch, of London, and, on leaving the ways, she was named the *Joseph Arbib* by Miss Bessie Dixon.

Inflexible.—On February 4th there was launched from the yard of Messrs. Short:Brothers, at Pallion, Sunderland, an iron screw steamer, built to the order of Messrs. Anderson, Horan, & Co., Sunderland, of the following dimensions and particulars :—Length between perpendiculars, 280 ft.; breadth, 38 ft.; and depth of hold, 27 ft. 6 inches, with a deadweight carrying capacity of about 3,250 tons. The vessel has been built to the highest class in Lloyd's Registry, under special survey, is constructed on the spar deck principle, and is fitted with long bridge over engines and boilers, with accommodation for officers, &c. The saloon is under the spar deck aft, and the vessel is divided into five water-tight compartments. The cargo can be worked from four large hatchways by a powerful steam winch at each. She has water ballast in fore and aft holds, and under engine and boilers, and is fitted with Emerson & Walker's windlass, and Bow, M'Lachlan, & Co.'s patent steam-steering gear, while the winches and donkey boiler are supplied by Messrs. Clark, Chapman, & Gurney, of Gateshead, and include all the latest improvements for despatch in working the vessel. On leaving the ways she was named the *Inflexible*, the ceremony of christening being performed by Mrs. Nuttall, of the Oaks. The vessel is to be fitted with engines and boilers of 180 horse-power, by Mr. John Dickinson, Monkwearmouth, with all the latest improvements in marine engineering.

DEPOSITING DOCK.—On February 4th the Barrow Shipbuilding Company launched from their yard a new depositing dock, built on Clark and Stanfield's patent, capable of accommodating vessels of nearly 3,200 tons displacement. It is built of iron, in the shape of the letter L, there being a series of twelve pontoons, each divided into four water-tight compartments by three transverse bulkheads, thus making forty-eight water-tight compartments. When a vessel requires to be docked for repairs, &c., the pontoons are sunk by being filled with water, and the vessel is placed on the top of them. By means of pumping the dock is made to float, and the vessel can if necessary be carried to a permanent staging now in course of erection on Old Barrow Island, where it can be deposited by the sinking of the pontoons, and the dock is thus released for a second vessel if occasion should require it. The dock can be extended in length and increased in power so as to dock and deposit vessels of 5,000 tons or even 6,000 tons displacement. A similar dock has been built and is now in successful operation in the south of Russia.

Treneglos.—On February 4th there was launched from the shipbuilding yard of Messrs. John Readhead & Co., South Shields, an iron screw steamer of the following dimensions—viz., 249 by 36 by 17½. The vessel has been built for Messrs. Edward Hain & Son, St. Ives, Cornwall, and will be classed 100 A 1 at Lloyd's. She will be fitted with engines of 120 horse-power, also built by Messrs. Readhead, and with Harfield's patent windlass, four steam winches, water ballast, six iron bulkheads, and all other modern requirements to fit her for a first-class Mediterranean boat. The vessel was named the *Treneglos* by Mrs. James Readhead.

Esk.—On February 4th a fishing smack was launched from the dockyard of the Whitby and Robin Hood's Shipbuilding and Graving Dock Company. Her dimensions are as follows :—Length extreme between perpendiculars, 74 ft. 6 ins.; extreme breadth, 19 ft. 9 ins.; depth of hold, per measurement, 10 ft. In all respects she will be fitted with all approved modern appliances for facilitating her movements, more especially in regard to the discharging of her cargoes. As she left slipway she was christened the *Esk* by Miss Robinson, daughter of Mr. B. Robinson, Esk-terrace.

Salerno.—On February 4th, Messrs. Osborne. Graham, & Co. launched from their yard at Hylton an iron screw-steamer. named the *Salerno*, built to the order of Messrs. R. W. Jones & Co., of Newport (Mon.). The vessel is of the following dimensions :—Length between perpendiculars 235 ft, by 33 ft. beam, and 16 ft. 9 in., depth of hold, to be classed 100 A 1 at Lloyd's. She will be fitted with compound engines by the North-Eastern Marine Engineering Company (Limited), of 120 horse-power, nominal, with cylinders 30 in., and 55 in., diameter, by 36 in., stroke. The vessel is provided with all appliances for rapid loading and discharging and with all recent improvements. There are three steam winches and donkey boilers, and she has a complete outfit, besides large hatches and shifting boards to enable her to pass the Board of Trade under the Grain Cargoes Act. On leaving the ways she was named by Mrs. Le Pelley, wife of Captain Le Pelley, who will take command.

Ealing.—On February 4th, a screw-steamer was launched from the building yard of Messrs. Hodgson & Soulsby, Blyth, of the following dimensions :—Length over all 292 ft.,; breadth extreme, 36 ft.,; depth of hold, 24 ft.,; carrying capacity, 3,000 tons—or say 12,500 qrs of heavy grain, besides 200 tons of fuel. The engines are compound direct acting surface-condensing 250-horse power nominal, and have been built by Messrs. R. & W. Hawthorn, Newcastle. The vessel has been built to the order of Messrs. Watts, Ward & Co., of London, Newcastle and Blyth, and is the second steamer constructed for this firm by Messrs. Hodgson & Soulsby. As the steamer glided down the ways she was named the *Ealing*, by Miss Arnison of Newcastle.

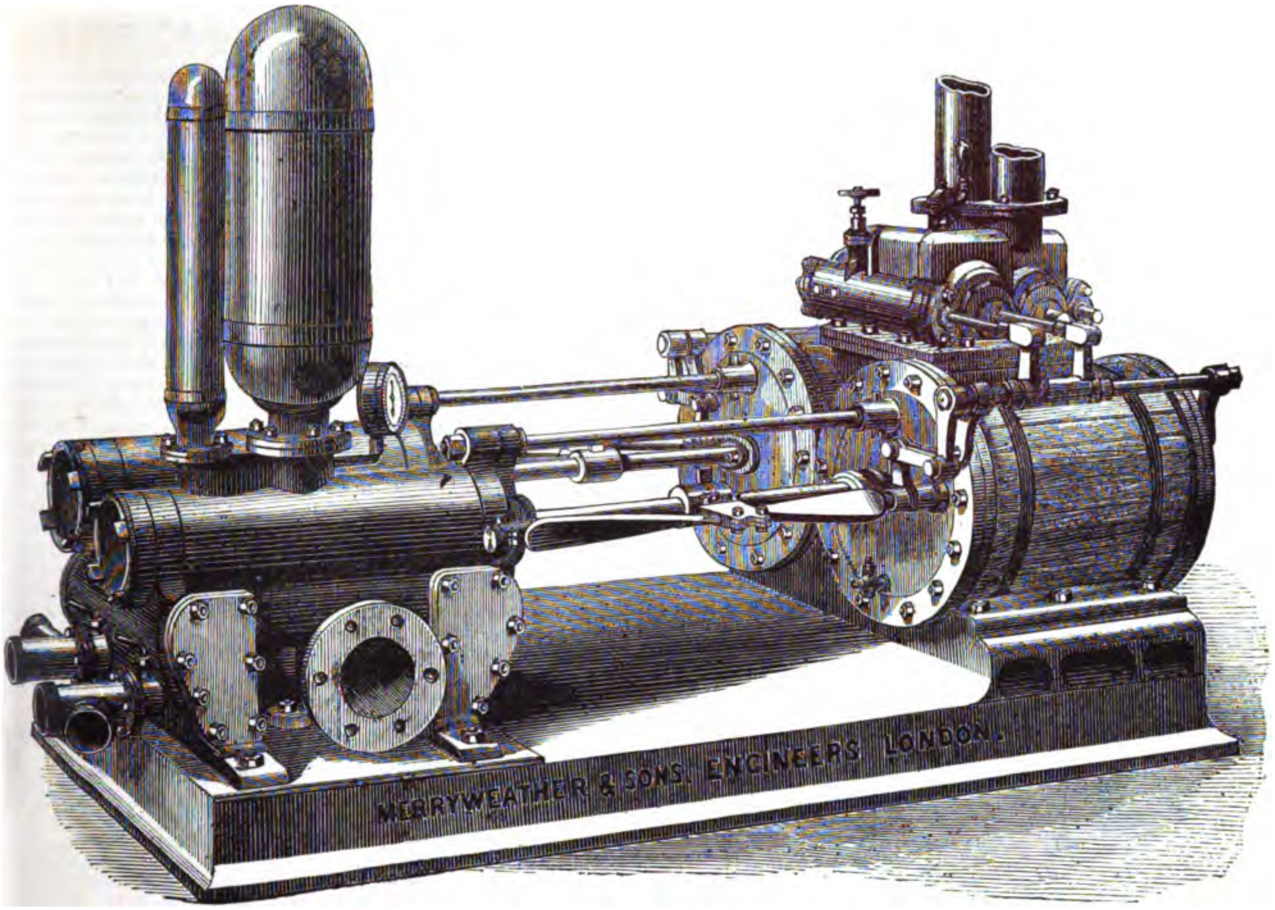
Boston City.—On February 6th Messrs. William Gray & Co., West Hartlepool, launched an iron steamship, to the order of Messrs. Thomas Furness & Co, of West Hartlepool, for their line between that port and America. Her dimensions are :—Length, 280 ft. breadth, 40 ft. depth 22 ft. 6 in., carrying capacity 3,000 tons deadweight. The engines of 250-horse power, will be supplied by Messrs. Blair & Co., of Stockton-on-Tees. She will be furnished with all the latest improvements, including water condenser capable of supplying 500 head of cattle and a large number of small stock, fittings for carrying which will be arranged on an entirely new plan, enabling the steamer to carry general cargo on her cattle decks when not occupied by live stock. On leaving the ways she was named the *Boston City*, by Miss Dora Furness. The *Boston City* was built under the superintendence of Captain T. King, the company's superintendent at West Hartlepool.

Haidar-Pasha.—On February 6th the steamer *Haidar-Pasha*, built to the order of Mr. W. J. Alt. for the Haidar-Pasha to Ismid Railway, was launched from the building yard of Messrs. Samuda Brothers, and was christened by Miss Mabel Alt. She is a paddle-wheel vessel, intended for crossing the neck of the Bosphorus and working in conjunction with the Ismid railway, and is 155 ft. long by 22 ft. with large deck accommodation for passengers, and is fitted with engines by Messrs. Maudslay & Field.

Lady Longden (s.s.).—On February 6th Messrs. Forrestt & Sons launched from their Britannia yard, at Millwall, a finely modelled steamer of the following dimensions :—Length over all, 125 ft.; length between perpendiculars, 120 ft.; breadth extreme, 20 ft.; depth moulded, 8 ft. 8 ins. The christening ceremony was performed by Miss Bond, who had been asked to represent Lady Longden on the occasion, that lady, who had promised to be present, having returned to India. The vessel is built of steel to take the highest class at Lloyd's. She is fitted with a bridge-deck amidships, poop, and topgallant forecastle. She will be schooner-rigged, and is intended to carry general cargo and passengers. The engines are of the compound condensing type, 15 ins. and 28 ins. diameter of cylinders, with a stroke of 21 ins. The vessel has been built to the order of T. A. Tambayah, Esq., of Colombo, and is intended as the pioneer vessel of a line of coasting steamers for Ceylon. Messrs. Forrestt & Son have also in hand four large iron steamers for a London firm, a large twin screw barge for H.M. Government, a powerful screw tug for London owners, four 80-ft. iron barges for India, besides numerous smaller iron and steel launches, &c.

Hesperia.—On February 7th, there was launched from the Barrow Shipbuilding Company's yard, Barrow-in-Furness, an iron screw steamer of the following dimensions :—Length, 338 ft.; breadth, 37 ft. 6 in.; gross tonnage, 3,100 tons. She will be supplied by her builders with engines of 480-horse power. As the vessel left the ways she was named the *Hesperia*, by Lady Ramsden. The *Hesperia* will be fitted with all the latest improvements, and is intended for the Atlantic trade.

Eastward.—On February 9th Earle's Shipbuilding and Engineering Company (Limited), launched from their yard a screw fishing cutter for the Great Northern Steamship Fishing Company (Limited), of Hull. The vessel was named *Eastward* by Miss Potter. This boat is built of iron, to class 100 A 1 at Lloyd's,



MERRYWEATHER & SONS. ENGINEERS. LONDON.

FIG. 5.—(*For Description see Page* 262.)

and is 135 ft. long between perpendiculars, 22 ft. beam, and 11 ft. deep. She has engines of 60 nominal horse power, having cylinders 21 and 40 in. diameter by 27 in. stroke, and is intended for carrying fish from the company's fleet to Hull.

Dodona.—On February 16th there was launched from the shipbuilding yard of Joseph L. Thompson & Sons, North Sands, Sunderland, an iron screw steamer, of 2,000 tons burthen, built to to class 100 A 1 at Lloyd's, and under special survey, to the order of Mr. Thomas Hick and partners, of Scarborough. After the launch the vessel was taken to the new quay of Mr. John Dickinson, where she has been engined. The engines are of 140 horse-power nominal; four steam winches, Emerson & Walker's patent windlass, Cooper & Taylor's steam stearing gear amidships, and all the modern appliances are being fitted. The accommodation for the captain and officers is in the full poop aft, being divided into fore and aft cabins; the engineer's berths are amidships, and crew accommodation in the topgallant forecastle. The naming of the vessel *Dodona* was performed by Miss Hick, of Scarborough. The *Dodona* is intended for the Mediterranean and Black Sea Trades, and will be under the command of Captain Thomas Pearson, of Scarborough.

Howards. - On February 18th Messrs. Robert Thompson & Sons successfully launched from their shipbuilding yard at Southwick, Sunderland, an iron screw-steamer for J. F. Marshall, Esq., Sunderland, of the following dimensions:—Length over all, 232 ft.; breadth, 32½ ft.; depth of hold, 16 ft., having been constructed under Lloyd's special survey to class 100 A 1. The vessel has long quarterdeck, bridge and topgallant forecastle, large hood aft covering steering gear and forming entrance to cabin, which is fitted up for captain and officers. Engineers and petty officers are placed under bridge, crew and firemen in forecastle. She has self-trimming hatches, iron plate rails, crane on forecastle, ample water ballast in both holds, also in peaks to enable vessel to trim well; steam winches and donkey boiler, Emerson, Walker & Co.'s patent windlass, Davis's steering gear amidships and screw gear aft. All deck fittings are made of iron. Schooner rig, and has all the latest improvements. Her engines are 130-horse power, by Messrs. Black, Hawthorn, & Co., of Gateshead. On leaving the ways she was named the *Howards*, by Mrs. Marshall, wife of the owner.

Pensher.—On February 18th Messrs. Short Brothers launched from their yard, at Pallion, Sunderland, a screw steamer, built for local owners, of the following dimensions:—Length, 240 ft.; breadth, 35 ft.; depth of hold, 18 ft., with a deadweight carrying capacity of 2,000 tons, The vessel has short poop, long raised quarter-deck, bridge-house over engines and boilers, and topgallant forecastle, water ballast, all fore and aft, four large hatches and steam winches, and all the latest improvements for despatch. On leaving the ways she was named the *Pensher*. She is to be fitted with engines, of 140 horse-power, by Mr. John Dickinson, with all the newest improvements in marine engineering.

Vendome.—On February 18th Messrs. Baxter & Co. launched from their yard at the North Sand Point, Sunderland, the screw steamer *Vendome*, built to the order of Messrs. Dansey & Robinson, of London, and intended for the coasting trade. The vessel, which is registered at Lloyd's in the highest class, is furnished with water ballast fore and aft, two steam winches, Emerson & Walker's patent combination windlass, bridge amidships, accommodation for captain and saloon amidships, full forecastle for crew and firemen, and all the most modern improvements. As the vessel was moving off the ways she was christened by Mrs. Baxter. The vessel has since left for the Tyne, where she will have compound engines, 60 horse-power, fitted by the Wallsend Slipway and Engineering Company (Limited). Her dimensions are as follows:—Length, 155 ft.; breadth, 23 ft. 6 ins.; depth of hold, 13 ft. 6 ins.

Dordogne.—On February 18th there was launched for the Cardiff Steam Shipping Company, Cardiff, by C. S. Swan & Hunter, Wallsend, Newcastle-on-Tyne, an iron screw steamer of the following dimensions:—Length between perpendiculars, 200 ft.; breadth, 29 ft. 3 ins.; depth, 15 ft. The vessel will carry about 1,050 tons deadweight, and is fitted with passenger accommodation, and will be employed on the line between Cardiff and Bordeaux. She will be fitted with engines 26 and 47 diameter ot cylinders, 36 length of stroke, 92 horse-power, by George Clark, Esq., Southwick, Sunderland. The vessel was named the *Dordogne* by Miss Hunter.

China.—On February 20th there was launched at Messrs. Palmer's shipbuilding yard, Jarrow, a screw steamer named the *China*, built for Messrs. R. Rubattino & Co., of Genoa. Her length is 412 ft.; breadth, 44½ ft.; depth. 31¾ ft. 3 in. Accommodation has been supplied for both first and second-clsss passengers, while the comfort of the crew has not been neglected. She has a deadweight carrying capacity of 4,500 tons, and water ballast in after hold. The vessel has been fitted with all the latest improvements. She is provided with eight boats, including one steam launch, built of steel, three cutters, also of steel, and four of wood. The engines are by Messrs. Palmer & Co., and are on the inverted, combined, self-acting, surface-condensing principle, with cylinders 54 and 96 in. respectively; 60 in. stroke, and 500-horse power nominal, with four cylindrical double-ended boilers, and two donkey boilers. The vessel is intended for the special mail service between Genoa and Bombay, and has been built under the personal superintendence of Captain Brizzolesi, of Genoa. Mrs. Price, wife of the general manager, performed the christening ceremony.

Jeanie.—On February 20th Messrs. Edward Withy& Co.launched from Middleton Shipyard, West Harplepool, an iron screw steamer, built to the order of Messrs. Coverdale, Todd & Co., of West Hartlepool. Her principal dimensions are:—Length between perpendiculars, 275 ft.; beam, extreme, 35 ft. 6 in.; depth, moulded, 20 ft. 9 in. She is built to Lloyd's highest class, and has poop, long quarter-deck, bridge-house, and topgallant forecastle extending to the foremast, double bottom all fore and aft on the cellular principle; the decks, masts, chart house, engine skylight, and cabin companion are of iron. She will be fitted with four hatches, steam winches, and patent windlass, and will be rigggd as a double topsail schooner; engines of 170-horse power wili be supplied by Messrs. T. Richardson & Sons, of Hartlepool Ironworks. This vessel is No. 105 in the builders' yard, and the fifth built by them for the same owners. She will be principally engaged in the Black Sea and Atlantic trades. On leaving the ways the steamer was christened *Jeanie*, by Miss Webster, daughter of Captain Webster, who will command her.

Middlesbrough.—On February 22nd there was successfully launched from the yard of her builders, Messrs. Raylton, Dixon, & Co., a steamship named the *Middlesbrough*, and which has been built to the order of Messrs. Hogg & Henderson, of this port. Her dimensions are:—Length over all, 250 ft.; breadth, 35 ft. 11in.; depth of hold, 15 ft. 6 in., and she will carry over 1,600 tons at 15 ft. 6 in. draught. She is built on the quarter-deck system, having bridge amidships, topgallant forecastle, iron decks, &c., according to the first class ships of this description, and she will be fitted with engines by Messrs. Blair & Co., Limited, Stockton, of 100 horse-power nominal.

LAUNCHES.—SCOTCH.

Hecuba.—On January 31st, there was launch from Messrs. Scott & Co.'s shipbuilding-yard at Greenock a crew steamer of 600 tons, which has been built to the order of Messrs. Alfred Holt & Co., of Liverpool. The dimensions of the new vessel, which was named the *Hecuba*, and is to be employed in the China trade, are as follows:—Length, 232 ft.; breadth, 32.6 ft.; and depth, 16.6 ft. Her cylinders are 22 and 46 inches, with a piston stroke of 36 in. She is fitted with an oval boiler to work to 80 lbs pressure. The new steamer was towed into the Victoria Harbour to be completed.

Norodom.—On February 1st, Messrs. Scott & Co., launched from their shipbuilding yard at Cartsdyke, Greenock, an iron screw steamer of about 430 tons register, built to the order of the Messageries Fluvials de Cochinchine, of Paris, and intended for the Cochin China trade. Her dimensions are as follows:—Length, 199 ft.; breadth, 26 ft. 3 in.; and depth, 15 ft. 6 in. Her cylinders are 24 in. and 48 in., with a piston stroke of 24 in. She is fitted with two circular boilers to work to 70 lbs pressure. As the vessel left the ways she was named the *Norodom*. The Chesapeake towed her to the East India Harbour, where she will be completed.

Lolland.—On February 1st. Messrs. H. M'Intyre & Co., launched from their shipbuilding-yard at Merksworth an iron screw-steamer of 700 tons. The vessel, which is named the *Lolland*, is built to the order of Det Lollandsk-engelske Dampskibsselskad, of Nakskov, Denmark, and is intended for the cattle trade between Denmark and Newcastle. She has an awning deck, and is fitted for cattle, is classed 100 A 1 at Lloyd's, and has all the most recent improvements in hull and machinery. Messrs. Hutson & Corbett, Glasgow, are the engineers. The *Lolland* has been built under the superintendence of Captain Fenger, who is to be her future Commander. The naming of the vessel was performed by Miss M'Intyre, Abbotsburn House, daughter of one of the builders.

Glenshee.—An iron barque of 850 tons register, named the *Glenshee*, was launched from the yard of Messrs. Alexander Stephen & Sons, Dundee. Her dimensions are:—Length, 204 ft.; breadth, 34 ft.; depth in hold, 19 ft. The vessel has been built to the order of Messrs. W. O. Taylor & Co., and is sister ship to the *Glenfarg*, which was launched last year for the same owners. Captain Wood, formerly of the ship *Glenlyon*, has been appointed to the command of the *Glenshee*. Messrs. Stephen have on hand two other ships of larger dimensions and of steel, for Messrs. W. O. Taylor & Co.

Birksgate.—On February 2nd, there was launched from the shipbuilding yard of Messrs. David & Wm. Henderson & Co., Meadowside Works, Partick, Glasgow, a screw steamer, classed 100 A 1 at Lloyd's, built under special survey, and of the following dimensions:—Length, 255 ft., breadth, 33 ft., depth 24 ft., moulded; and having a gross tonnage of 1,450 tons. This vessel is built on the cellular system, and has water ballast both fore and aft. She is fitted up with steam steering gear, three steam winches steam windlass, and all appliances for the rapid loading and discharge of cargo, and has accommodation for 50 first and 50 second-class passengers. She is built to the order of A. L. Elder, Esq., for Messrs. Simpson, of Adelaide, and intended for their colonial trade, As the vessel left the ways she was named *Birksgate* by Miss Black. After the launch the vessel was towed alongside the builders' wharf, where they will fit her with compound machinery of 1,200 indicated horse power, having all the most modern improvements. On completion she will steam out to Australia, under the command of Captain M'Kenzie, who has superintended the construction of the vessel.

Pelican.—On February 6th there was launched from the shipbuilding yard of Messrs. Barclay, Curle & Co., Whiteinch Glasgow, an iron screw steamer of 2,550 tons, for Messrs, Slater, White & Co., Leith. On leaving the ways she was named the Pelican by Mrs. James Gilchrist, 7, Kelvingrove-terrace.

Glenogle.—On February 7th the London & Glasgow Shipbuilding & Engineering Company launched from their yard at Govan, a large addition to the Glen Line fleet of tea clippers, named the *Glenogle*, for service between London and China—the managing owners being Messrs M'Gregor, Gow, & Co., Glasgow and London. The new vessel took the water in splendid style, and the ceremony of naming her was performed by Miss Reid, daughter of Mr Reid, of Kilmardinny. The *Glenogle* is the largest steamer built for the company. her dimensions being:—Length 440 ft., breadth 45 ft., depth, 29 ft., 2 in., with a gross tonnage of 4,000. She is built on the cellular system, with sharply defined lines, and to the highest class at Lloyd's and all the Board of Trade requirements. In addition, the new Glen Liner has been specially surveyed by the Admiralty officials, and put on the list of cruisers which can be used in the event of war with another maritime nation, and also for the conveyance of troops, The engines which are being built by the firm to the design and specifications of Mr. Wm. C. Roberts are of the three cylinder type, one of these being 59½ and two of 83½ in., diameter and 60 in., stroke, having all the latest and several new improvements, and when in full working order are expected to develop at least 5,250-horse power. Her equipments will include Messrs. Muir & Caldwell's steam steering gear, Messrs Napier Brothers' hand steering gear and windlass, Messrs Clarke's steam winches, and Messrs Chapman & Gurney's patent cranes. The *Glenogle*, besides carrying a large cargo, will be fitted up for a limited number of first-class passengers, and in the internal fittings teakwood will be largely used, and the saloon the saloon and berths are to be heated by steam-pipes.

Alora.—On February 7th, Messrs. Henry Murray launched from their Port Glasgow yard an iron screw steamer named the *Alora* of the following dimensions:—Length, 193 ft., breadth of beam, 27 ft., depth of hold, 14 ft., 500 tons register; and built to the highest class at Lloyds. Messrs James Howden & Co., Glasgow, will supply the engines. The *Alora* has been built to the order of Messrs. Goodyear & Co., Liverpool, and is to be engaged in trading between London and the Mediterranean. Captain Pearce will be in command.

Henry Swayne.—On February 16th, Messrs. Russell & Co., launched from their Port Glasgow yard an iron barque of the following dimension:—Length, 190 ft., breadth of beam 30 ft., 6 in., depth of hold 18 ft., 700 tons. As she left the ways the vessel was named *Henry Swayne.* by Mrs. Paterson, wife of the Captain. The *Henry Swayne* is a sister ship to the Bandeeth, and has been built for Messrs. W. & J. Lockett, Liverpool. She will load in Port Glasgow for Valparaiso.

Sherbro.—On February 18th, Messrs. John Elder & Co., launched from their shipbuilding and engineering works, Fairfield, Govana, steel screw steamer of about 1,700 tons gross, and of the following dimensions:—Length between perpendiculars, 300 ft.; breadth, 36 ft.; depth of hold, 19 ft. 11 in. This vessel is specially designed to have large carrying capacity, combined with light draught of water, and is for that reason entirely built of steel. She will thus be enabled to cross the bars, which are situated at the entrance of most of the African ports, and save the necessity of transhipping the cargo to shallow-draught vessels. The engines, which are being supplied by the same firm, are on their compound principle, with all the latest improvements, and will develop 1,200-horse power indicated, which will give a speed of about 12 knots an hour. The vessel, though intended principally for cargo, will have accommodation on deck for about 20 passengers, besides officers, engineers, and crew, and will be fitted with steam windlass, steam winches, steam steering gear, and all the latest improvements. This vessel has been built for the British and African Steam Navigation Company, of Glasgow, is classed 20 years in red at the Liverpool Underwriters' Registry, and is similar to the *Coansa* and *Malemba*, built in 1880 for the same company. As the vessel left the ways she was named the *Sherbro* by Mrs. Robert Cowan M'Kinnon, of Hillhead.

Mentmore.—On February 19th, a screw steamer was launched from Messrs. J. Key & Sons' shipbuilding-yard, Kinghorn. Arrangements had been made for the launch taking place on Saturday at 2. 30, but when all was ready a telegram from the insurance company was received warning the builders that if the launch took place then, the wind and sea being most unpropitious, it would not be at the risk of the company. Accordingly, the launch was arranged to come on Sunday at 3. 30 P.M., and it was accomplish in a most successful manner. She was named the *Mentmore*, and will trade from Liverpool. She was thereafter towed by three tugs to Leith, where she will be fitted out for the American cattle and meat trade. The customary naming ceremony was performed by Miss Bond, sister of one of the partners. The *Mentmore* will receive her engines and fittings at Leith.

Falls of Afton.—On February 20th, Messrs Russell & Co., Cartsdyke, Greenock, launched a four-masted iron sailing ship, of 1,900 tons, which has been built to the order of Messrs. Breckinridge & Co., of Glasgow, and is to be employed in the East India Trade. The dimensions of the new vessel are:—Length, 268 ft.; breadth, 41 ft.; and depth, 23 ft. 9 in. On leaving the ways the vessel was named the *Falls of Afton*.

Earl of Powis.—On February 20th Messrs Robert Duncan & Co., launched at Port Glasgow, an iron screw steamer named the *Earl of Powis*, of the following dimensions:—Length, 130 ft.; breadth of beam, 21 ft.; depth of hold, 7 ft., 6 in.; registered tonnage, 116. This steamer has been built for the Shropshire Union Canal Company (London and North-Western Railway Company), and is to trade betwean Liverpool and Chester. She has been fitted for towing barges and carrying passengers, and is classed 20 years in the Liverpool register. A pair of patent compound disconnecting twin-screw engines will be supplied by Messrs. Rankine & Blackmore, Greenock.

Alexandra.—On February 20th, a new patent hopper dredger of 500 tons, built and engined by Messrs. William Simons & Co., was launched complete from their works at Renfrew. It is the property of the Manchester, Sheffield, and Lincolnshire Railway, and has been constructed under the direction of Mr. Sacre, C. E., their engineer; it is the second hopper dredger supplied to them by this firm. This vessel is fitted with twin screws, and two sets of separate compound engines, and two boilers of 80 horse-power; its bucket girder traverses beyond the bow for the purpose of cutting shoals or dry banks, and thus dredge its own flotation down to 25 ft. depth of water; it will carry 500 tons of its own dredgings at a speed of seven miles per hour, and on board are fitted steam appliances for mooring, lifting, dreding, traversing and manoeuvring.

Arracan.—On February 21st Messrs Robert Duncan & Co. launched at Port Glasgow a screw steamer of the following dimensions:—Length 346 ft.; breadth of beam, 40 ft.; depth of hold, 25 ft.; 2,880 gross tonnage, 1,855 tons nett. As she left the ways she was named the *Arracan* by Miss Emma Thomson, daughter of one of the directors of the British & Burmese Steam Navigation. Co., Glasgow (Messrs. P. Henderson & Co., agents), for which company the steamer has been built. She has been fitted for 30 first-class and 20 second-class passengers, and has full poop, bridge, and topgallant forecastle. The *Arracan* is to be engaged in the Rangoon trade. The engines, which are to be compound direct-acting vertical, will be supplied by Messrs. Denny & Co., Dumbarton; cylinders 38 in.; and 68 in.; with 51-in.; stroke, and of 290-horse power. Immediately after the launch the *Arracan* was towed to Dumbarton.

Clan Macdonald.—On February 21st Messrs. Scott & Co., shipbuilders, Cartsdyke, Greenock, launched from their yard an iron screw steamer, of 2,800 tons register, built to the order of Messrs. Cayzer, Irvine & Co., Glasgow, the owners of the Clan Line of steamships. The dimensions of the vessel are as follow:—Length, 330 ft.; breadth, 39 ft.; and depth, 28 ft. She will be supplied from the Greenock Foundry Company with a pair of powerful compound engines, the cylinders of which are 41 and 71 inches in diameter by 48 inches stroke. She will be fitted with two double-ended boilers, 12 ft. 9 in. each by 18 ft. in length, to a working pressure of 80 lbs. to the square inch. On leaving the ways she was named the *Clan Macdonald*. After the launch the steamer was towed to the Victoria Harbour, where her engines and boilers will be put on board.

Clan Cameron.—On February 22nd a splendid iron screw steamer, of about 2.600 tons, for Messrs. Cayzer, Irvine & Co.'s Clan Line, was launched from Messrs. Alexander Stephen & Sons' shipbuilding-yard at Linthouse, and was named the *Clan Cameron* by Mrs. Ogilvie, 1, Doune-teraace, Kelvinside. This steamer is the fifth constructed for the Clan owners by Messrs. Stephen—who have three more in hand for the same line. She is built under special survey to class 100 A1 three-deck rule in Lloyd's (for which she is considerably in excess of Lloyd's requirements), and the engines, which are also by Messrs. Stephen, are of the most improved compound surface-condensing type, with cylinders 38 in. and 68 in. diameter by 45 stroke, and ample boilers suitable for a working pressure of 85 lbs. The first-class passenger accommodation is in a house aft, beautifully designed and very prettily finished; the officers are located in houses amidships, and a topgallant forecastle is provided for the crew. Great attention has been paid throughout to ventilation. The vessel is amply supplied with steam-steering gear, steam winches, and all the best modern appliances for working purposes. She has also provision for water ballast in double bottom on the bracket principle throughout, and is fitted with the extra water-tight bulkheads required by the Admiralty in order to taking a place on the list of vessels suitable for transports.

Casino.—On February 21st, Messrs. Gourlay Brothers & Company launched a handsome iron screw-steamer. The vessel is of the following dimensions:—Length between perpendiculars, 160 ft.; depth of hold, 10 ft. 3 in.; beam moulded, 24 ft.; and register, 426 tons. The vessel has been built to the order of Mr. B. B. Nicoll, of Sydney, for his coast trade between Sydney and the Richmond River. As the vessel left the ways she was named *Casino* by Mrs. J. Y. Guthrie, of Rosebery Crescent, Edinburgh. The *Casino* is a very handsome model, and is superbly fitted up for carrying a large number of passengers, the saloon being in the hurricane deck amidships, forward of all machinery, oil smell &c. She has a long topgallant forecastle, under which her second class passengers are accommodated. She is rigged with three masts, and is intended, like all the other vessels built for the firm, to carry a large cargo on a light draught. A steam revolving crane and two steam winches have been fitted, and all appliances for quickly handling cargo are of the most modern description. She is supplied by the builders with a pair of modern compound engines of about 70 horse-power nominal, and a large multitubular steel boiler, intended to drive the vessel about 10 knots. The *Casino* is built under the special survey of the Board of Trade, and classed 90 A at Lloyd's. She will be ready for sea in about three weeks, when she will leave for Australia. The *Casino* is the fifth steamer built by the Messrs. Gourlay for the Messrs. Nicoll. The steamer is fitted to carry 42 saloon and 26 second class passengers.

Helen Nicoll.—On February 21st, Messrs. Gourlay Brothers & Co. launched a handsome iron screw steamer, named the *Helen Nicoll* by Miss Maggie Nicoll, daughter of the owner. Like the *Casino*, the *Helen Nicoll* is intended for general cargo and passenger trade, and has been designed with a view to carrying a large cargo on a light draught; and to ensure a good speed a pair of the builders' high and low pressure compound engines of about 65-horse power nominal, with a large multitubular steel boiler, have been supplied. A very handsome saloon, fitted under hurricane deck amidships, with separate ladies' saloon on upper deck, combined with thorough ventilation, will meet the necessities of a warm climate. The whole of the saloon fittings are most elaborate. The *Helen Nicoll* will be rigged as a brigantine, and will carry a good spread of canvas. The passenger accommodation is amidship, forward of engines and boilers, and occupies the whole width of the ship. The appliances for cargo are very complete, there being three steam winches and large donkey boiler. Accommodation for the officers, galley, &c., is fitted on the quarter-deck. After shipping engines and boilers at the large crane the vessel will be completed with all speed and dispatched for Australia, her owner sailing with her. The dimensions of the *Helen Nicoll* are:

—Length, 157 ft.; breadth, 22 ft.; depth, 10 ft. 3 in.; and register, 383 tons. She is classed 90 A at Lloyd's. The launch was witnessed by a large party of the friends of the Messrs Nicoll.

LAUNCHES.—IRISH.

Pollie Whittaker.—On January 21st, a three-masted schooner was launched from the shipbuilding-yard of Mr. Paul Rodgers, Carrickfergus. Her dimensions are:—Length, 109 ft.; breadth of beam, 24 ft. 2 in.; depth of hold, 12 ft.; register tonnage about 192. She has been classed at Lloyd's for 12 years A 1. The ceremony of christening was performed by Mrs. Dixon, wife of Captain Robert Dixon, who will command the new vessel, which will henceforth be known as the *Pollie Whittaker*.

Mary E. Wadham.—On February 2nd a screw steamer was launched from the iron shipbuilding yard of Messrs. M'Ilwaine & Lewis, Abercorn Basin, Belfast. The vessel, which is 190 ft. long, 27 ft. broad, with 15 ft. 6 in. breadth of beam, and 850 tons deadweight and capacity, was built to the order of Messrs. George Bargate & Co., of Barrow-in-Furness. The engines are 90 nominal horse-power, and the cylinders 24 and 46 diameter, with 36 in. stroke, and she is expected to steam between 10 and 11 knots with full cargo. She has a double bottom on the bracket system, and is in every respect fitted as a high-class ship, being built under special survey, and is classed at the highest standard at Lloyd's. She was christened the *Mary E. Wadham* by Mrs. Wadham, of Millwood, Dalton-in-Furness.

British Prince.—On February 4th a very fine screw steamer was launched from the shipbuilding-yard of Messrs. Harland & Wolff, Queen's Island, Belfast. This vessel is the fifth of the same class that has been built for the British Shipowners' Company, of Liverpool, and is of the following dimensions:—Length, 420 ft.; breadth of beam, 42 ft.; gross tonnage, 4,000 tons. She is built of Siemens and Martin's steel, and will be classed 100 A1 at Lloyd's. Her engines will be 4.000-horse power. She has four masts, and the steam windlass, steam winches, and steam steering-gear will be on the most improved principle. She will probably be in a position to proceed to sea in about six weeks. The *British Prince* will be placed on the Atlantic trade, the same as sister vessels which are now running between Liverpool and Philadelphia. She is now lying in the Abercorn Basin, and will be fitted up as rapidly as possible. It may be mentioned that another vessel in the stocks will be ready for launching in a short time.

LAUNCH.—FRENCH.

Dupuy de Lôme. On February 5th the "Forges et Chantiers de la Mediterranee," launched from their Graville Shipbuilding yard near Havre, an iron screw steamer built for the "Compagnie Commerciale de Transports a' Vapeur Français" of Havre, the pioneer of a new line between Havre and New-Orleans. The dimensions of the vessel are: Length over all 390 ft. length between perpendiculars 376 ft.; breadth moulded 40 ft. Depth moulded 32 ft. tonnage net registered 2,700 tons, gross tonnage 3,400 tons. The vessel will be fitted by the same firm with direct acting surface condensing compound engines of 1,600 indicated horse-power. She will carry about 4,600 tons deadweight and has been built under special survey to the first class in "Bureau Veritas" register. She is spar-decked, with two iron decks, rigged with four iron masts and provided with the latest modern improvements for loading and discharging, five steam winches, steam windlass, Stapfer de Dudo's patent steering gear, etc., The vessel, on leaving the ways was named *Dupuy de Lôme* by Mrs G Dupuy de Lôme, daughter-in-law of the celebrated naval architect. After the launch which was accomplished most successfully on the direction of Mr. A. Marmiesse, chief constructor of the shipyard, the *Dupuy de Lôme* was towed into the Havre docks for the purpose of having the masts and engines put on board.

LAUNCH.—ITALIAN.

Birmania.—On January 29th there was launched from the shipbuilding yard of Messrs. Orlando Bros. an iron screw steamer of 3,100 tons, built to the order of Messrs. Rubatino & Co. Her dimensions are as follows:—Length, 310 ft.; breadth, 36 ft.; depth, 28 ft. She is schooner rigged, and has a raised forecastle, while aft there is a spacious dining saloon. She contains all the latest improvements for the rapid working of cargoes, including steam windlass, two steam winches, and three steam cranes; also Muir & Caldwell's patent steam steering gear, four iron ship's boats and two gigs. She will be fitted with compound surface-condensing engines of 1.100 indicated horse-power. There will be accommodation for fifty first class passengers, large dining saloon, smoking-room, lavatories, &c. The launch was in every way a success, the christening ceremony being gracefully performed by the Signora Scelsi, wife of the Prefect of Leghorn, who named the steamer the *Birmania*. Among the visitors were the two Princes of Birmany, who are studying at the Royal Italian Naval College at Leghorn.

LAUNCHES.—SWEDISH.

Asernoy.—On January 20th there was launched from the yard of the Motala company at Norrköping a twin screw steamer, built to the order of the Russian government. This steamer, which will be used for inspections of the great canal system between the lakes in Russia, is of the following dimensions:—Length, 137 ft.; breadth, 19 ft.; draught of water aft 5 ft., fore 4 ft. 6 in.; the machinery, of 50 nominal horse power, will give the vessel, which is of a very fine model, a good speed. At the same yard there was launched on January 4th a screw steamer which will be fitted with an engine of 60 nominal horse power. The company Södern at Norrköping will be the owners. The principal dimensions are as follows:—Length, 130 ft.; breadth moulded, 23½ ft.; draught of water, 9½ ft. This steamer is intended for cargo as well as passengers, and will be fitted with the latest improvements for quick despatch. The material in both these steamers is of the Motala works own make.

Oslo.—On January 31st was launched from Kockum's shipbuilding yard, Malmö, Sweden, a cargo steamer *Oslo*, built for the Christiania Steamship Company, in Norway. The steamer measures 225 ft. in length, 31 ft. in breath, and 15 ft. 3 in. depth of hold. She is spar-decked, built to Lloyd's survey class 100 A 1, and will be engined by the builders with compound engines of about 600 indicated horses. The steamer will carry about 1200 tons and is the first of two twin steamers for the same company.

LAUNCH.—FINLAND.

Murmansky.—On January 26th Messrs. Wm. Chrichton & Co., launched from their shipbuilding yard at Abo, Finland, an iron screw steamer, built for a Company in St. Petersburg, who are already the owners of several steamers trading on the Murmansky Coast and Wardoe Islands in the White Sea. This steamer which has the highest class French Lloyds is of the following dimensions: length, 167 ft., breadth, 22 ft., depth of hold, 11 ft., and has a draught of 8 ft. She is to be fitted with a compound surface condensing engine of 360 indicated horse power, water ballast, steam winches and all the latest improvements, and is to be ready for sea by the 1st of June. The keel of the *Murmansky* was laid in the end of September last, she having thus been built in the short time of four months. A launch at this time of the year in Finland is of rare occurrence, and could not have taken place if the winter had not been so unusually mild as it is, seeing that the river, where the before-mentioned vessel was launched, would under ordinary circumstances have been frozen over with ice 3 ft. thick.

TRIAL TRIPS.

Ranelagh.—On January 27th the *Ranelagh* (s), built and engined by Messrs. John Key & Sons, of Kirkcaldy, was taken out of the harbour and underwent a most satisfactory trial. The distance run was on each occasion five miles, being between Inchkeith and Oxcar Beacon, which was run both with and against tide, giving the following results:—First run, with 70 revolutions, 25 min. 50 sec. equal to 11·615 knots against wind and tide; second run, with 76 revolutions, 20 min. 53 sec., equal to 14·40 knots with wind and tide, giving a mean speed of 13·1 knots per hour, being three-quarters of a knot per hour above the guaranteed speed. The following are the principal dimensions of the vessel:—Length, 204 ft.; breadth, 29 ft.; depth of hold, 19 ft. 2 in. The engines are 160-horse power nominal, having cylinders 30 in. and 60 in., with 39-inch stroke, capable of developing 1,000-horse power indicated. The steamer is built to the order of the Australian Steam Navigation Company, and sails for Sydney direct.

Caliban.—On January 27th, the screw steamer yacht *Caliban* made a most successful trial at sea. She has been built to the order of a French nobleman for the Mediterranean by Messrs. Edwards & Symes, of London. Her length is 112 ft. over all, breadth, 16 ft. 4 in.; and depth of hold, 10 ft. 6 in.; and fitted by the builders with compound surface condensing engines of the highest class, and finish of 35-horse power nominal, she has been built under the highest class at Lloyd's, is fitted with a most unique steam windlass of special design, which does its work most efficiently. Amidships she has a handsome panelled polished teak deckhouse with a clear height of 7 ft. inside, above which is the bridge and steering gear. The cabin accommodation is on a scale most unusual for a yacht of her tonnage, the cabins and saloons being both large and lofty, panelled in polished pitch pine, mahogany, and teak, with brass and electro plated fittings, upholstered in utrecht velvet and cabin stores with Wilton tiles and polished brass mountings. She is fitted with three pole masts fore and aft, schooner rigged with awnings all fore and aft, and on the sea trial of two hours made an average speed of nearly 11 knots per hour, the machinery working most satisfactory and is the largest steam yacht that has been built on the Thames for some years, and is a credit to this enterprising firm, who have others building.

Foscolino.—On January 28th the new steamship *Foscolino*, the first built to the order of the Wear Steamship Company (Limited), managed by Messrs. R. Wrightson and Sayers, of the Exchange, Sunderland, ran a successful trial. The *Foscolino* was launched five weeks ago from the yard of Messrs. Pickersgill, Southwick, and she is 230 ft. in length, 31 ft. in breadth, 15 ft. 6 in. in depth, of 716 tons nett register, and has a carrying capacity of 1,400 tons, whilst the most improved machinery necessary for a cargo steamer has been provided. Her engines, which are on the compound surface-condensing principle, have cylinders of 27 in. and 50 in. diameter, with a 30-inch stroke, and during the trial ran 78 revolutions to the minute, developing 520-horse power, and a mean speed of 10 knots per hour.

Eleanor.—On January 30th, the London and North-Western Railway Company's new paddle steamer *Eleanor*, just completed by Messrs. Laird Brothers, Birkenhead, left the Mersey and proceeded to Holyhead to take her place on her station; and the run was considered as the official trial trip. There was a heavy sea on, and, the weather being hazy, the course steered was longer than it otherwise would have been; but, notwithstanding these disadvantages, the run from the Rock Light to the end of the Holyhead Breakwater was accomplished in three hours and 54 minutes, which gives a mean speed of 16 knots an hour. The engines worked splendidly, and developed about 1,850 indicated horse power, and the trial was considered highly satisfactory in all respects. The *Eleanor*, it may be mentioned, is the 500th vessel built and finished by Messrs. Laird, and the eighth built by them for the London and North-Western Railway Company, and, like the *Isabella*, *Lily*, and *Violet*, she is constructed of steel manufactured at the railway company's works at Crewe. Her dimensions are:—Length, 253 ft. 6 in.; beam, 31 ft.; depth in hold, 14 ft. 6 in., with a tonnage of 1,118 tons O.M. She is fitted with two distinct sets of compound oscillating engines, which can be worked either together for regular work, or immediately disconnected by steam gear and worked independently for manœuvring the vessel in difficult circumstances. The passenger accommodation is contained in a full poop, entirely shut off from that part of the deck where the cattle are stowed, and comprises a saloon about 45 feet long and the full width of the vessel. On the lower deck forward are comfortable second-class cabins and special accommodation for drovers. Fittings are provided for about 400 head of cattle, besides sheep, and special care has been devoted to the ventilation of the holds and 'tween decks.

Rydal Fell.—The screw steamer *Rydal Fell*, recently launched from the yard of Messrs Murdoch & Murray, Port Glasgow for the new Fell Line of steamships, went down the Clyde for her trial trip on February 1st. After having compasses adjusted in the Gareloch, she proceeded to the measured mile to test the working of the engines and speed of the vessel. The machinery, which was fitted on board by Messrs. Dunsmuir & Jackson, Govan, worked in every way to the satisfaction of the owners, Messrs. Hume, Smith & Co., The average speed attained was 11¼ knots per hour.

Ludgate Hill.—On February 2nd, this twin screw steamer, another of the large steel vessels recently built by Messrs. Dobie & Co., was taken down the Clyde upon the official trial trip. The dimensions of the *Ludgate Hill* are—420 ft. in length; 47 ft. in breadth; and 26½ ft. in depth; having a gross tonnage of 4,162 tons, and deadweight capacity of 5, 200 tons, with engines of 600-horse power nominal, supplied by Messrs. James Howden & Co., and the speed attained exceeded 14 knots. The appointments and outfit of the present steamer, like those which preceded her, are of the most substantial kind.

Afrikann.—On Feb. 10 a new steamer, named the *Afrikann*, for trade between Rotterdam and the West Coast of Africa, which has been built by Messrs. Raylton, Dixon, & Co., to the order of the New African Steamship Company, of Rotterdam, proceeded on her trial trip from the Middlesbrough Docks. She is built on the spar-deck rule, and is 225 ft. long between perpendiculars, by 31 ft. beam and 22 ft. depth of hold to spar deck, and will carry over 1,300 tons on 16 ft. draught. The has iron main deck laid with wood, cabin aft for captain and a few passengers, with accommodation under the bridge for her officers and engineers, and chart room and steam quartermaster for steering. Her engines, of 100 horse power nominal, by Messrs. Blair & Co., of Stockton, worked most satisfactorily, and all gave complete satisfaction to a small company of her owners, officers, and builders, who witnessed her trial trip.

Ahdeek. (*s*)—On February 14th, the screw steamer *Ahdeek*, launched from the yard of Messrs. Short Pallion. in December last, to the order of Messrs. Walker & Butchart, West Suniside, had a trial trip to sea, which proved of a highly satisfactory character. The dimensions of the *Ahdeek* are:—Length 245 ft.; breadth 34 ft. 6 in.; depth of hold 18 ft., 6 in.; deadweight carrying capacity, 2,050 tons; and she is classed in Lloyd's highest list, having been built under special survey. Intended for the general carrying trade, care has been taken to provide the most approved appliances for the purpose of navigation, or for the shipment and discharge of cargo, including four steam winches (one to each hold), Harfield's patent windlass, steel wire ropes, and Higginson's Quartermaster steam steering gear. After the compasses had been adjusted, a run was made to Marsden and back, for the purpose of testing the engines. These were supplied by the North-Eastern Marine Engine Company, and are on the compound surface condensing principle, Allan's patent, with cylinders 32 in. and 61 in. diameter and 36 in. stroke. During the trial they worked without a hitch maintaining a pressure of 79 lbs, vacuum 26½ in.; and performed 60 revolutions per minute, indicating 750-horse power. The log showed that fully 10 knots an hour had been attained.

Merton Hall.—On February 20th this vessel left Dundee to make her trial trip in the North Sea, and went as for as Aberdeen. Her machinery worked very satisfactorily. The average speed from the river to Aberdeen was 11½ knots per hour, and from the Bell Rock to the Bay of Tay her speed was 12 knots,

The *Canada*, one of the numerous corvettes of the *Comus* class, which was launched at Portsmouth on August 26th last, went out of harbour on February 15th, for a contractor's six hours' full power trial of her engines in the Solent. After one hour's steaming, the forward crank pin heated to such a degree that it was necessary to ease the engine down to dead slow, and put a stop to the trial. The engines were afterwards worked to half-speed for the purpose of testing the jet injection. The forward drop rudder was also tried, but in consequence of the trim of the ship, the value of the experiment was of the slightest. During the hour the ship was maintained at full power, a speed of over 14 knots was realised, while the horse power, indicated was 2,332·76, or 33 horses over the contract power. The *Canada*, went out of harbour again on Friday, February 17th, for a six hours' contractors' full-power trial of her engines. Captain Colomb, of the Steam Reserve, took command of the ship, while the machinery was watched on behalf of the Admiralty by Mr. John Oliver, the Steam Reserve being represented by Mr. J. H. Ellis, Chief Inspector of Machinery, and the Factory Department of the Dockyard by Mr. E. Newman, Chief Engineer. The forward draught of the ship was 14 ft. 2 in., and the after draught 17 ft. 8 in., giving a mean draught of 15 ft. 11 in. She was, therefore, very light as compared with her mean load draught, which is 17 ft. 9 in.; but she was brought down by means of iron ballast 3 ft. 6 in. by the stern, so as to give her screw the proper degree of immersion. The ship got under way at eight o'clock, but the first observations were not made until half-past nine, care being taken to work up the steam gradually to avoid all danger of hot bearings. At the end of the six honrs's continuous running the following means were obtained:—Steam in boilers, 58·33 lb.; vacumn, 27·5 in. forward and 27·1 in. aft; revolutions per minute, 104·94; mean pressure, 39·37 lb. in the high-pressure and 11·31 lb. in the low-pressure cylinders; total indicated horse-power, 2,432·73. This is very satisfactory, being in round numbers 133-horse power above the contract, without having had recourse to the blast. The speed realised, as tested by several runs on the measured mile, was 14,177 knots per hour. The *Canada* returned into harbour at the end of the trial, and will be completed for commission.

Athabasca.—This new steamer has been built by Messrs. M. Pearse & Co., Stockton-on-Tees, to the order of Messrs. Tapscott & Co., of Liverpool. This steamer has been constructed of extra strength, and built to the highest class in Lloyd's. The following are the dimensions:—Length between perpendiculars, 300 ft.; breadth of beam, 38 ft. 6 ins.; and depth of hold, 27 ft. 6 ins. Her total deadweight capacity is 3,300 tons. She has a forecastle, bridge, and poop. The bridge is carried to the afterside of the engine room to give extra protection to the engines and boilers in heavy weather; the bulwarks are 4 ft. high, which are left open opposite the hatches to allow the seas to run quickly off her decks. She is fitted with Donkins, Nichol, & Co.'s steam steering gear, and Dunlop, Bell, & Co.'s steam winches, and Suffield's patent volutical fresh water condenser. The old cat and fish davits have been done away with, and a single strong crane is made to take their place. This arrangement has given great satisfaction on the other steamers belonging to the same owners. The engines are constructed by Messrs. Blair & Co., Limited, of Stockton-on-Tees. The diameter of the cylinders are 38 in. by 71 in., and 45 in. stroke, with a boiler pressure of 80lbs. per square inch, the boilers are fitted with Fox's patent corrugated furnaces. The speed obtained on her run from the Tees to the Tyne, where she was taken to load, was 11 knots, the engines working very smoothly at the rate of 64 revolutions per minute under easy steam, and she proved a most satisfactory vessel in every respect, and gave great satisfaction to the owners and Mr. F. J. Pilcher, consulting engineer, of Liverpool, under whose superintendence the vessel was built.

Peter the Great,—On January 30th, the Russian turret-ship *Peter the Great*, which came to the Clyde a few months ago in order to be supplied with entirely new engines by Messrs. Elder & Co., of Glasgow, went down the Clyde on her first preliminary trial trip. She left the anchorage at noon, and returned shortly after four o'clock. Though not under full steam at any time during the trip, she succeeded in attaining an average speed of 12½ knots per hour.

The Douglas.—On February 15th, this steamer, launched some time ago by Messrs. Hall, Russell & Co., went out to the Aberdeen Bay for trial of speed, and gave very satisfactory results, attaining a speed of 13½ knots per hour, with the engines working very smoothly and indicating 1,425-horse power. *The Douglas* leaves Aberdeen direct for China in about two weeks.

Recent Applications for Patents connected with Marine Engineering, Ship Construction, and Mechanical Appliances for use in Ships, from 24th January 1882, to 20th February, 1882.

292 H. Lumley. Rudders.
333 P. B. Delany (communicated by T. J. Handyford). Electric cables.

EDITORIAL NOTES.

THE ship railway, suggested by Captain Eads, over the Isthmus of Panama, has been allowed to sleep for a long time. It is, however, now being brought prominently forward in America, and money is being asked for its construction. Now that it has reached so practical a form it may be worth our while to give it some attention. There can be little doubt that if vessels can be successfully lifted by hydraulic power on to dry docks, as they are in Messrs. Stansfield & Clarke's dock, that a similar appliance can be used to lift vessels of any burthen on to a suitable cradle for land transit. The propulsion, then, of such a carriage on an inland railroad is only a question of sufficient propelling or hauling power, and a metalled road-way of requisite stability. So far, all is within the reach of modern engineering enterprise, though on a gigantic scale, and at enormous cost. The main difficulty will arise with the question of what should be the best form for the bearing or rolling surfaces of the carrying cradle. As a very average rule the weight of any carrying truck on railways is, at least, half that of the load, and a weight of 10 tons is about all that can be put on any pair of wheels and axle of the ordinary construction and on the usual road-way. To deal then with a vessel of only 4,000 tons, the carriage will weigh another 2,000 tons, and if carried on ordinary rails and axles would require to be distributed over 600 pairs of wheels. For driving power we may estimate that a heavy locomotive can only just take 200 tons up an incline of one in 100, which gradients Captain Eads expects to meet with. To deal with the vessel of 4,000 tons and carriage 30 heavy locomotives would be required. As many iron clads are much over 4,000 tons in weight, and the weight of ocean-going steamers are constantly on the increase, the foregoing figures are but a mild estimate of the difficulties to be encountered in such an enterprise.

WE see that the application of the Siren fog signals are to be very largely increased. They have been tested by the Admiralty, the Corporation of the Trinity House, and foreign Governments, at great expense during the last few years. The Siren is to be adopted in her Majesty's Royal Navy, and should prove of great value for giving signals from vessel to vessel in foggy weather. We see that a very good hot air or caloric engine has been used very extensively with Holme's Sirens for driving purposes. This engine, which is the invention of Mr. Buckett, though not much known in the outside market, has already been largely applied around our coasts compressing the air for fog signalling. This engine seems to be very economical in its work, requiring only 2½ lbs. of fuel per horse-power generated. The fire-place is closed hermetically, the air being forced in through the fuel. As the heated products of combustion from the coke are used direct, in moving the piston there is no chimney required. A pressure of 37 lbs., it is stated, can be maintained in the engine, and there is an entire absence of danger from fire or explosion. The supply of air is regulated by the action of the engine itself. We note that a large and influential company is being formed to manufacture and supply the Sirens to all navies and coasts, and to supply the Buckett hot air engines to the open market.

AGAIN is the question of the relative strength of the British Navy, as compared with those of the other countries, brought prominently forward for discussion. Lord Henry Gordon has embodied a series of speeches in the form of a pamphlet, entitled "Fore-warned, Fore-armed," in which this comparison of force is carried on as far as 1885. At present our number of iron clads are but little in excess of those of France, and in looking forward to the year 1885 the author of the pamphlet fears that England's present small supremacy will have disappeared. For ourselves, we think that these scares may be useful in keeping our attention to what we are doing towards keeping up our navy, and that it should be the best of its kind; but, at the same time, should war arise, we should always find some friend to swell our number of available ships, and if not, it is still quite an open question whether fast unarmoured cruisers with heavy guns, torpedoes, and great ramming power and speed, such as could be drawn at any time from our mercantile marine, would not go far to decide the command of the sea.

APPARENTLY, aerial voyages will soon become as popular as those on the more stable element, water. In spite of the lamentable accident which has so lately cast a shadow on aerial enterprise, we find that Colonel Burnaby has successfully accomplished a balloon voyage across the Channel. His experience has served to point out that much discrimination and coolness is required by the aeronaut to avail himself of those currents of wind which will drive him in the required direction. For instance, although Colonel Burnaby started with a wind favourable to his purpose, when he had almost attained the coast of France the wind veered round to south-south-west, and he began to drift back to sea. He, however, immediately rose to a higher altitude, and found there his original current which safely carried him over Normandy, where he descended without danger or difficulty. Mr. Coxwell and another independent party are both about to make similar trips to France. If these several excursionists prove that steady currents can be relied on at certain altitudes we shall probably find balloon voyaging to the Continent become a popular amusement.

APPARENTLY, Mr. Chamberlain's suggestion of the establishment of a Shipping Council is about to bear fruit. We see that the Newcastle Local Marine Board have adopted several resolutions upon the composition and powers of a Board, which they would recommend to the Board of Trade. The suggestions are these:—1. That the powers at present vested in the officers of the Board of Trade to stop unseaworthy ships and overloaded ships should be continued. 2. That the existing regulations as to the optional load-line marks should not be interfered with or altered. 3. That in all cases of detention of ships and steamers on the alleged ground of overloading or unseaworthiness, or from any cause, an immediate appeal should be made to the local shipping council, constituted as suggested in the sixth resolution. 4. That the shipping council for the Newcastle district shall include Hartlepool, Sunderland, North Shields, South Shields, Newcastle, and Berwick. 5. That the local marine boards of the suggested district should be reconstructed and made into a local shipping council. 6. That the local shipping council should consist of shipbuilders, engineers, legal gentlemen, and shipowners, and seafaring men; so many to be elected by the Board of Trade, and so many by the shipowners. 7. That a shipping council so constituted would be composed of the most competent men of the district, and their decisions in all matters of dispute between the officers of the Board of Trade and the shipowner could not fail to command the confidence of all parties. 8. That a local shipping council would afford a ready and inexpensive mode of settling all disputes as to unseaworthiness, overloading, or other alleged causes for detaining ships by the officers of the Board of Trade, and would put an end to the cruel, expensive, and oppressive litigation so justly complained of by the shipowners and the Board of Trade.

THE Americans are determined to carry out their project of carrying their mails in American bottoms. A Bill is being pressed through Congress, appropriating 25,000,000 dols., as a subsidy divided into ten equal annual instalments, and distributed as follows:—One-fifth to the Pacific Coast; two-fifths to Philadelphia and the ports of the north; and two-fifths to Baltimore and the ports of the south, including the Gulf. The subsidy is only to be given to ships owned, manned and built by Americans. They are to be of 4,000 tons, running at 18 knots; 3,000 tons, running at 14 knots; 2,000 tons, running at 13 knots; and 1,000 tons, running at 11 knots respectively. The English mails are to be carried at 18 knots, with a subsidy of 33 dols. per mile, half for each voyage, and the other services are 30 dols., 25 dols., and 20 dols. respectively. As this subsidy represents ten per cent. approximately on the costs of the ships, leaving entire receipts from freight and passenger traffic to cover expenses, it is a great catch for the American ship owners and builders, though evidently at the cost of the ratepayers.

LLOYD'S RULES AS AFFECTING MARINE BOILER CONSTRUCTION.[*]

By J. T. MILTON, Esq., Assistant Chief Engineer Surveyor to Lloyd's Register, Member.

April 30th.

AT a recent meeting of the Institution of Mechanical Engineers at Newcastle, a notable paper was read by Mr. F. C. Marshall on "The Progress of Marine Engineering," in which appears a statement to the effect that "the ordinary marine boiler, encumbered as it is by the regulations of the Board of Trade and of Lloyd's Committee, does not admit of much reduction in the weight of material or of water carried when working." Mr. Kirk, in the discussion which followed, remarked that "a locomotive boiler which is considered safe on a railway would not be passed for use in a steamer at the same pressure;" while, in replying on the discussion of the paper, Mr. Marshall explained that though he did not complain of the restrictions, "yet restrictions existed, and as long as they did exist they would have difficulty in modifying the form of marine boilers materially," and he endorced the remarks as to the locomotive boiler on shipboard. Such statements as these, coming from such well-known authorities, and so widely circulated as they have been, will in my opinion, tend to produce the erroneous impression in the minds of shipowners that Lloyd's Register is an obstructive institution, preventing them from obtaining all the advantages of high-steam pressure. In the present paper I shall endeavour to prove that this is not the case, by showing that the only restrictions imposed by Lloyd's Register are such as are actually demanded by considerations of safety. I would here venture to remark that the experience of the surveyors to Lloyd's Register, gained in the periodical examinations of marine boilers of all types, gives them exceptionally good opportunities of judging not only of the original strengths required for the structures to withstand the wear and tear to which they are subjected, but also of the defects of different modes of construction; as probably no persons in the kingdom have so many and such varied examples of marine boilers of all descriptions, of all ages, and in all stages of corrosion passing continually under their inspection. First, as to the restrictions regarding forms or types of boilers. Lloyd's Rules require any novelty in the construction of either boilers or machinery to be specially submitted to the Committee at as early a date as possible. The merits and demerits of each plan thus submitted are very carefully considered, and in very few cases indeed have the Committee of Lloyd's Register refused entirely to sanction any arrangement which has been proposed to be actually used. In every case of novel boilers in which it was evident that the original design or a modification of it fully provided for safety, unconditional approval has been given, whilst in many cases in which it is considered that the continued efficiency and safety of the boilers for long periods are dependent upon more than ordinary care and attention being bestowed upon them, they have been approved of, subject to their being frequently submitted to survey. I may mention that nine types of novel boilers have been passed unconditionally by Lloyd's Register, six types have been approved of, subject to frequent re-survey, while the Perkins' and Howard boilers are the only types which have been strongly objected to and disallowed. Of these novel boilers, those of the last-mentioned types have already been taken out of the s.s. *Wanderer* and *Howard* respectively, at the instance of their owners, and replaced by others of ordinary form; of the nine passed unconditionally, two have been taken out of the vessels in which they were fitted, and two have been materially modified, after a few months' trial, on account of their not giving economical results equal to the anticipations of their designers, not in either case on account of their having proved to be dangerous; of the five types of boiler approved of subject to frequent examinations, the results in every case have proved that the restrictions prescribed have been absolutely required, one type of boiler fitted in two coasting steamers having been found to have become somewhat damaged in the short space of three months between consecutive surveys; whilst two sets of similar boilers fitted in unclassed vessels making longer voyages, and therefore not subjected to the same amount of supervision, became absolutely dangerous, through their having been allowed to become dirty, and these have had to be removed. I think that this clearly shows that so far as *form* of boilers is concerned, any restrictions imposed by Lloyd's Register have not been uncalled for, while I think it will be conceded without question that on the subject of the use of mild steel for marine boilers coming to the front, the action taken by Lloyd's Register in approving of its use, on being satisfied of its quality, greatly facilitated its introduction. Next, with regard to the restrictions imposed by Lloyd's Register in the matter of strength. All structures must be made with a strength in excess of the load which they are designed to bear, in order to provide for their safety in the event of the occurrence of any or all of the following contingencies:—Latent defects or plans in the material. Errors or defects of workmanship. Exceptionally severe strains which may possibly be brought to bear upon the structures by causes other than those which they are designed to resist. The weakening effects of corrosion or wear and tear.

Upon the relative probabilities of the occurrence of these contingencies in different structures depends the excess of strength required in their design, the proper allowance for each of the causes being determined by actual experience. In the case of marine boilers, it is with the last-mentioned cause that we have principally to deal. As I have previously stated, the surveyors of Lloyd's Register possess exceptional advantages in observing the effects of corrosion, and this experience was brought to bear upon the subject at the time when the rules for the strengths of boilers were revised some three years ago. I have recently examined into the original scantlings of a large number of boilers made by eminent firms of marine engineers, and fitted on board vessels classed in Lloyd's Register just prior to the time when the officers of that Society commenced to survey machinery, confining my examination to the cases in which the boilers had not been built under Board of Trade supervision, and where the manufacturers were, therefore, to a large extent untrammelled and left free to carry out their own ideas on the subject of strength; and in every one of these cases the boilers would now be allowed by Lloyd's rules to work at a pressure, considerably above that for which they were designed. I find that on an average they would be allowed 25 per cent. greater pressure as regards the cylindrical shells, 44 per cent. greater pressure as regards the combustion chamber plating, 38 per cent. as regards stays, and 38 per cent. as regards furnaces, while in many cases the strengths far exceeded these averages. Of course, in regard to the surplus excesses of furnaces, and to some extent also in some cases in regard to the combustion chamber plates, it is difficult to work exactly down to any fixed rule, as an extra 1-32 on the thickness of the plate will increase the strength about 15 per cent.; but there is no such difficulty in regard to the shells, and this large margin shows that Lloyd's Rules in this case have not thrown obstructions on the previous practice, while the fact that the present rules are now worked down to by nearly all makers seems to show that, on the contrary, by inspiring confidence in less scantlings, they have really led the way for an increased pressure being carried by the same type of boiler to the extent of at least 25 per cent. That this confidence has not been misplaced is shown by the remarkable immunity from serious accidents of boilers which have been passed by Lloyd's Register; but, at the same time, I will endeavour to show that much, if any, further reduction of scantling would be imprudent, taking into account the deterioration to which all parts of boilers are liable.

First, let us take the case of cylindrical shells, the great thickness of which is the greatest obstacle at present to the carrying of increased pressures with the present type of boiler. Lloyd's Rules provide a different co-efficient of stress for boiler shell plates, according as the longitudinal seams are made with lap or butt-strapped joints, and as the rivet holes in these joints are drilled or punched, the co-efficients also varying with the thickness of the plate employed. Messrs. Parker & John some time ago carried out a series of experiments in order to determine the loss of strength of steel plates occasioned by punching the rivet holes without subsequently annealing the plate, and at the same time, in order to obtain comparative results in the case of iron, they made similar experiments with various thicknesses of iron plates. Their experiments showed, without doubt, that iron loses considerably in strength by punching, although to a less extent than steel; but we can scarcely assume that the loss of strength is less than 10 per cent., as in most cases it was found to be more than this. Lloyd's Rules provide for a stress of about 10 per cent. less being borne by punched plate than by the same plate in which the holes are drilled; at the same time, as experiments do not show that rivets are any stronger in drilled than in punched holes, the same stress is practically allowed upon them in each case by reducing the larger co-efficient of stress by 10 per cent. so far as the rivets are concerned for cases in which the holes are drilled. Practically, if boiler plate unpunched is credited with a strength of 20 tons per square inch, Lloyd's Rules credit the punched plates, and also the rivets either in punched or drilled holes, with a strength of 18 tons per square inch. Lloyd's

---

[*] Read at the Twenty-third Session of the Institution of Naval Architects; the Right Hon. the Earl of RAVENSWORTH, President in the Chair.

Rules in new boilers made with lap joints allow a stress of 7,750 and 8,500 lbs. per square inch with thin plates, say 6-16 thick, according as the holes are punched or drilled, in 9-16 plates they allow 8,250 and 9,000 lbs., in 13-16 and thicker plates they allow 8,500 and 9,500 lbs. per square inch respectively. These figures, neglecting all possible imperfections of workmanship, and assuming a strength of plate of 18 and 20 tons per square inch respectively give a margin of strength of 5·2, 4·9, and 4·7 times respectively. If these plates become uniformly corroded to the extent of 1-16 of an inch, the same working pressure will produce stresses of about 9,300 lbs. and 10,200 lbs. per square inch in each case, the margin of strength being in all cases reduced to about 4·4 times, while a corrosion of 1-8 of an inch in the three cases reduces this margin to 3·5, 3·8, and 4·0, and a corrosion of 3-16 brings these numbers to 2·6, 3·3, and 3·6 respectively. This amount of corrosion is not an uncommon amount to be met with in boiler shells six or eight years old, and would so lessen the strength of the thinner plate as to demand a considerable reduction of the working pressure, while even in the thicker plate the margin of strength is less than many prudent engineers would care about working with, considering that these figures do not provide for any contingency as to defective material or workmanship. In shell plates fitted with double butt straps, if the straps are originally made somewhat thicker than the half of the thickness of the plates, a considerable uniform corrosion can take place without weakening the joint at all. For instance, suppose the butt straps are made ¾ the thickness of the plate, and the strength of the joint is made to be originally 75 per cent. of that of the solid plate, then a uniform corrosion to the extent of ¼ of the thickness of the plate, will reduce throughout to that of the riveted joint, so that the only loss of strength the structure would receive is that gained by the crossing of the joints—an amount which experiments have shown to be very small, with the wide plates now generally used. On the other hand, corrosion is often very far from uniform, and in the event of a leaky joint—a by no means unknown occurrence in the bottoms of boilers—the corrosion always found at neglected leaky places will attack the weakest place, the joint itself, and will really weaken the structure. Taking these points into consideration, Lloyd's Rules allow a greater stress with double butt strapped joints than with lap joints, although not so much greater as the uniform corrosion theory alone would justify.

Coming now to stays; the greatest stress allowed is 6,000 lbs. per square inch calculated from the smallest part of the stay, both with large and small stays; but when we consider that large stays are almost invariably made with raised threads and have the ends welded on, and that the strength of the welds cannot be relied upon to be equal to that of the rest of the bar, and also that the smaller screw stays have the threads left on them and are thus to some extent protected from corrosion, we see that a very appreciable amount of corrosion on each will be required to bring their strength to an equality. In flat plates supported by stays, and also in circular furnaces subjected to external pressure, we find a deal of difficulty in estimating the pressure which will produce a given amount of stress. In all the experiments on these joints with the results of which I am aquainted, the principal point observed has been the ultimate pressure producing rupture or collapse. In some only of the cases have the bulges and sets at the different pressures been carefully observed, while the critical pressure at which permanent set was first produced has in most, if not all, of the experiments on flat plates, to be estimated to be between two pressures, more or less widely apart, as the stages at which the observations were made were few or numerous. For instance, in some of a very extensive set of experiments made recently it is recorded that there was no set or bulge at 50 lbs., and 1-64th set at 100 lbs. in one case, while in another there is no set recorded at 200 lbs. and 1-32nd set at 300 lbs. pressure, the results thus giving no definite knowledge as to the exact proof pressure within 50 per cent. of the truth in the first case and 33 per cent. in the second. Experiments conducted in this way are nearly useless, as far as concerns any light they throw upon the elastic or useful strength of flat plates supported by stays.

Now in most structures the stress produced in any part is proportional to the load producing it, not only up to the elastic or proof stress, but also up to the ultimate strength of the material, so that an experiment giving the ultimate strength of the structure will also give a fair idea of its proof or elastic strength, if the ratio of the proof stress to the ultimate strength of the material is known. In the cases both of flat plates and furnaces, however, this does not hold good. With both, so soon as the proof strength is exceeded, the ratio of stress to load becomes widely different from what it was before. In the case of the flat plates, when a large amount of bulging has been produced by the pressure, the material is evidently wholly in a state of tension, whereas up to the proof strength the material must be in tension only where it becomes convex, and in compression where it becomes concave. The ultimate pressures such plates will bear are therefore, with ductile material, considerably more than double their proof pressures, being more proportional to the ductility or power of stretching than to the original stiffness or rigidity of the plates. Further, it is to be remarked that in all boilers, it is impossible to keep the plates exposed to the action of the heat of the furnace gases absolutely clean, and a very thin scale upon the water side of the plate is sufficient to offer such an obstruction to the flow of heat through it that the plate must become somewhat overheated, and when more than a very thin scale is allowed to accumulate, the plates must get very hot, and lose considerably in rigidity. This contingency has to be provided for, as well as the loss of strength due to corrosion. As a matter of fact, we find that very few, if any, old boilers have their chamber plates unbuckled, whilst, in very many comparatively new boilers, the plates are largely bulged through overheating alone, although they are found to be of their original thickness and to have a large margin of strength when cold. These considerations must not be lost sight of when comparing the pressures which are allowed in practice with the ultimate strengths found by experiments upon cold plates. Lloyd's Rules give a larger coefficient for ½ inch than for 7-16th plates, thus to some extent providing for corrosion, and they also give a greater coefficient for plates in which the stays are fitted with nuts than for those in which the heads are riveted, on account of the greater security afforded by the former method of securing the stays where buckling of the plates is to be apprehended. With regard to the Rules as they are at present for flat plates, I think I may safely say that they do not throw any serious obstacle in the way of working with a pressure of 200 lbs. per square inch, which largely exceeds any pressure that is either being used or contemplated at present, whilst experience gained with old boilers does not warrant any reduction of scantlings from those now required. In the cases of furnaces, we very much require some elaborate and costly experiments to determine the true law as to their actual strengths, the number of experiments made on full-sized furnaces up to the present being very small. Fairbairn's experiments were made principally on small models, and the rule he deduced, or modifications of it, have generally been used by engineers in designing flues, but, unfortunately, this rule does not well apply to the dimensions of furnaces usually adopted in marine boilers. For instance, it cannot be considered that a flue 7 ft. long and 3 ft. 6 in. diameter, made of ½-inch plates, would have its strength doubled by fitting an anti-collapsing ring at the middle of its length—a result which Fairbairn's Rule would lead one to suppose.

Recently, Mr. Fox, of Armley, Leeds, has made some experiments on flues about 7 ft. long and 3 ft. diameter, but as his experiments were made solely as a means of comparison of plain v. corrugated flues, various lengths and diameters were not necessary for his purpose, and were accordingly not used. In these experiments it is to be noted that all the plain flues collapsed at a much lower pressure than that deducible from Fairbairn's Rule, from their dimensions and thickness. Although there is such a lack of experiments giving the actual collapsing pressures of furnaces, we have an immense number of experiments of a negative character. The great number of actual furnaces at present running safely show that their collapsing pressure is at least greater than that at which they work, and thus prove that the rules by which they were designed provide at least sufficient strength for practical purposes, while not one of the many cases coming under my knowledge of actual collapse of furnaces at the ordinary working pressure has been due to constructive weakness. In some of the cases the cause has been clearly seen to be shortness of water, in others it has been the accumulation of lime-scale, in several others it has been the accumulation of a peculiarly tenacious scale, apparently principally composed of precipitated carbonate or sulphate of lime from the water, intimately mixed with mineral oil from the cylinders.

A very thin coating of this greasy deposit appears to be quite as non-conducting as a much thicker deposit of crystalline scale. Several collapses are traceable to a deposit of common salt, through allowing the density of the water in the boiler to gradually accumulate up to the saturation point; and in one at least of the two or three cases in which the furnaces have lately collapsed, but have been found to be perfectly clean on the vessel's arrival in port, this accumulation of salt has been the cause of the accident, but the engineers have, by freshening the water after the accident, dissolved the deposit. All these cases come under the category of overheating, not of structural weakness, for although the use to which furnaces are put necessitates their being raised to a temperature somewhat above that of the steam, and therefore requires their being made thicker than would suffice to withstand the working pressure if they were always cold, yet no thickness of plate whatever will give sufficient rigidity at a red heat to prevent such accidents if they are subjected to such conditions.
